Design fire scenarios come from two sources: those that are specified in 5.5.3.1 through 5.5.3.8, and those that are developed by the design team based on the unique characteristics of the building as required by 5.5.2. In most, if not all, cases, more than one design fire scenario will be developed to meet the requirements of 5.5.2.

Once the set of design fire scenarios is established, both those specified by 5.5.3.1 through 5.5.3.8 and those that are developed as required by 5.5.2, they need to be quantified into a format that can be used for the evaluation of proposed designs. The *SFPE Engineering Guide to Performance-Based Fire Protection* outlines a process and identifies tools and references that can be used at each step of this process.

A.5.5.2 The protection systems and features used to meet the challenge of the design fire scenario should be typical of, and consistent with, those used for other similar areas of the building. They should not be designed to be more effective in the building area addressed than in similar areas not included and that are, therefore, not explicitly evaluated.

A.5.5.3 It is desirable to consider a wide variety of different fire scenarios to evaluate the complete life safety capabilities of the building or structure. Fire scenarios should not be limited to a single or a couple of worst-case fire scenarios.

The descriptive terms used to indicate the rate of fire growth for the scenarios are intended to be generic. Use of *t*-squared fires is not required for any scenario.

A.5.5.3.1 An example of Design Fire Scenario 1 for a health care occupancy would involve a patient room with two occupied beds with a fire initially involving one bed and the room door open. This is a cursory example in that much of the explicitly required information indicated in 5.5.3.1 can be determined from the information provided in the example. Note that it is usually necessary to consider more than one scenario to capture the features and conditions typical of an occupancy.

A.5.5.3.2 Design Fire Scenario 2 examples include a fire involving ignition of gasoline as an accelerant in a means of egress, clothing racks in corridors, renovation materials, or other fuel configurations that can cause an ultrafast fire. The means of egress chosen is the doorway with the largest egress capacity among doorways normally used in the ordinary operation of the building. The baseline occupant characteristics for the property are assumed. At ignition, doors are assumed to be open throughout the building.

A.5.5.3.3 An example of Design Fire Scenario 3 is a fire in a storage room adjacent to the largest occupiable room in the building. The contents of the room of fire origin are specified to provide the largest fuel load and the most rapid growth in fire severity consistent with the normal use of the room. The adjacent occupiable room is assumed to be filled to capacity with occupants. Occupants are assumed to be somewhat impaired in whatever form is most consistent with the intended use of the building. At ignition, doors from both rooms are assumed to be open. Depending on the design, doorways connect the two rooms or they connect via a common hallway or corridor.

For purposes of this scenario, an occupiable room is a room that might contain people; that is, a location within a building where people are typically found.

A.5.5.3.4 An example of Design Fire Scenario 4 is a fire originating in a concealed wall or ceiling space adjacent to a large, occupied function room. Ignition involves concealed combustibles, including wire or cable insulation and thermal or acoustical insulation. The adjacent function room is assumed to be occupied to capacity. The baseline occupant characteristics for the property are assumed. At ignition, doors are assumed to be open throughout the building.

A.5.5.3.5 An example of Design Fire Scenario 5 is a cigarette fire in a trash can. The trash can is close enough to room contents to ignite more substantial fuel sources but is not close enough to any occupant to create an intimate-with-ignition situation. If the intended use of the property involves the potential for some occupants to be incapable of movement at any time, the room of origin is chosen as the type of room likely to have such occupants, filled to capacity with occupants in that condition. If the intended use of the property does not involve the potential for some occupants to be incapable of movement, the room of origin is chosen to be an assembly or function area characteristic of the use of the property, and the trash can is placed so that it is shielded by furniture from suppression systems. At ignition, doors are assumed to be open throughout the building.

A.5.5.3.6 An example of Design Fire Scenario 6 is a fire originating in the largest fuel load of combustibles possible in normal operation in a function or assembly room, or in a process/manufacturing area, characteristic of the normal operation of the property. The configuration, type, and geometry of the combustibles are chosen so as to produce the most rapid and severe fire growth or smoke generation consistent with the normal operation of the property. The baseline occupant characteristics for the property are assumed. At ignition, doors are assumed to be closed throughout the building.

This scenario includes everything from a big couch fire in a small dwelling to a rack fire in combustible liquids stock in a big box retail store.

A.5.5.3.7 An example of Design Fire Scenario 7 is an exposure fire. The initiating fire is the closest and most severe fire possible consistent with the placement and type of adjacent properties and the placement of plants and combustible adornments on the property. The baseline occupant characteristics for the property are assumed.

This category includes wildlands/urban interface fires and exterior wood shingle problems, where applicable.

A.5.5.3.8 Design Fire Scenario 8 addresses a set of conditions with a typical fire originating in the building with any one passive or active fire protection system or feature being ineffective. Examples include unprotected openings between floors or between fire walls or fire barrier walls, failure of rated fire doors to close automatically, shutoff of sprinkler system water supply, nonoperative fire alarm system, inoperable smoke management system, or automatic smoke dampers blocked open. This scenario should represent a reasonable challenge to the other building features provided by the design and presumed to be available.

The concept of a fire originating in ordinary combustibles is intentionally selected for this scenario. This fire, although presenting a realistic challenge to the building and the associated building systems, does not represent the worst-case scenario or the most challenging fire for the building. Examples include the following:

(1) Fire originating in ordinary combustibles in the corridor of a patient wing of a hospital under the following conditions:
   (a) Staff is assumed not to close any patient room doors upon detection of fire.
   (b) The baseline occupant characteristics for the property are assumed, and the patient rooms off the corridor are assumed to be filled to capacity.
   (c) At ignition, doors to patient rooms are not equipped with self-closing devices and are assumed to be open throughout the smoke compartment.
(2) Fire originating in ordinary combustibles in a large assembly room or area in the interior of the building under the following conditions:
   (a) The automatic suppression systems are assumed to be out of operation.
   (b) The baseline occupant characteristics for the property are assumed, and the room of origin is assumed to be filled to capacity.
   (c) At ignition, doors are assumed to be closed throughout the building.
(3) Fire originating in ordinary combustibles in an unoccupied small function room adjacent to a large assembly room or area in the interior of the building under the following conditions:
   (a) The automatic detection systems are assumed to be out of operation.
   (b) The baseline occupant characteristics for the property are assumed, the room of origin is assumed to be unoccupied, and the assembly room is assumed to be filled to capacity.
   (c) At ignition, doors are assumed to be closed throughout the building.

A.5.5.3.8(3) The exemption is applied to each active or passive fire protection system individually and requires two different types of information to be developed by analysis and approved by the authority having jurisdiction. System reliability is to be analyzed and accepted. Design performance in the absence of the system is also to be analyzed and accepted, but acceptable performance does not require fully meeting the stated goals and objectives. It might not be possible to meet fully the goals and objectives if a key system is unavailable, and yet no system is totally reliable. The authority having jurisdiction will determine which level of performance, possibly short of the stated goals and objectives, is acceptable, given the very low probability (i.e., the system's unreliability probability) that the system will not be available.

A.5.6 The *SFPE Engineering Guide to Performance-Based Fire Protection* outlines a process for evaluating whether trial designs meet the performance criteria during the design fire scenarios. Additional information on reviewing the evaluation of a performance-based design can be found in the *SFPE Code Official's Guide to Performance-Based Design Review*.

The procedures described in Sections 5.2 and 5.4 identify required design fire scenarios among the design fire scenarios within which a proposed fire safety design is required to perform and the associated untenable conditions that are to be avoided in order to maintain life safety. Section 5.6 discusses methods that form the link from the scenarios and criteria to the goals and objectives.

Assessment methods are used to demonstrate that the proposed design will achieve the stated goals/objectives by providing information indicating that the performance criteria of Section 5.2 can be adequately met. Assessment methods are permitted to be either tests or modeling.

Tests. Test results can be directly used to assess a fire safety design when they accurately represent the scenarios developed by using Section 5.4 and provide output data matching the performance criteria in Section 5.2. Because the performance criteria for this *Code* are stated in terms of human exposure to lethal fire effects, no test will suffice. However, tests will be needed to produce data for use in models and other calculation methods.

Standardized Tests. Standardized tests are conducted on various systems and components to determine whether they meet some predetermined, typically prescriptive criteria. Results are given on a pass/fail basis — the test specimen either does or does not meet the pre-established criteria. The actual performance of the test specimen is not usually recorded.

Scale. Tests can be either small, intermediate, or full scale. Small-scale tests are used to test activation of detection and suppression devices and the flammability and toxicity of materials. Usually, the item to be tested is placed within the testing device or apparatus. Intermediate-scale tests can be used to determine the adequacy of system components — for example, doors and windows — as opposed to entire systems. The difference between small- and intermediate-scale tests is usually one of definition provided by those conducting the test. Full-scale tests are typically used to test building and structural components or entire systems. The difference between intermediate- and large-scale tests is also subject to the definition of those performing the test. Full-scale tests are intended to most closely depict performance of the test subject as installed in the field; that is, most closely represent real world performance.

Full-scale building evacuations can provide information on how the evacuation of a structure is likely to occur for an existing building with a given population without subjecting occupants to the real physical or psychological effects of a fire.

Data Uses. The data obtained from standardized tests have three uses for verification purposes. First, the test results can be used instead of a model. This use is typically the role of full-scale test results. Second, the test results can be used as a basis for validating the model. The model predictions match well with the test results. Therefore, the model can be used in situations similar to the test scenario. Third, the test results can be used as input to models. This is typically the use of small-scale tests, specifically flammability tests.

Start-Up Test. Start-up test results can be used to demonstrate that the fire safety system performs as designed. The system design might be based on modeling. If the start-up test indicates a deficiency, the system needs to be adjusted and retested until it can be demonstrated that the design can meet the performance criteria. Typically, start-up tests apply only to the installation to which they are designed.

Experimental Data. Experimental data from nonstandardized tests can be used when the specified scenario and the experimental setup are similar. Typically, experimental data are applicable to a greater variety of scenarios than are standardized test results.

Human and Organizational Performance Tests. Certain tests determine whether inputs used to determine human performance criteria remain valid during the occupancy of a building. Tests of human and organizational performance might include any of the following:

(1) Measuring evacuation times during fire drills
(2) Querying emergency response team members to determine whether they know required procedures
(3) Conducting field tests to ensure that emergency response team members can execute tasks within predetermined times and accuracy limits

Design proposals should include descriptions of any tests needed to determine whether stated goals, objectives, and performance criteria are being met.

Modeling. Models can be used to predict the performance criteria for a given scenario. Because of the limitations on using only tests for this purpose, models are expected to be used in most, if not all, performance-based design assessments.

The effect of fire and its toxic products on the occupants can be modeled, as can the movement and behavior of occupants during the fire. The term *evacuation model* will be used to describe models that predict the location and movements of occupants, and the term *tenability model* will be used to describe models that predict the effects on occupants of specified levels of exposure to fire effects.

Types of Fire Models. Fire models are used to predict fire-related performance criteria. Fire models can be either probabilistic or deterministic. Several types of deterministic models are available: computational fluid dynamics (CFD or field) models, zone models, purpose-built models, and hand calculations. Probabilistic fire models are also available but are less likely to be used for this purpose.

Probabilistic fire models use the probabilities as well as the severity of various events as the basis of evaluation. Some probabilistic models incorporate deterministic models, but are not required to do so. Probabilistic models attempt to predict the likelihood or probability that events or severity associated with an unwanted fire will occur, or they predict the "expected loss," which can be thought of as the probability-weighted average severity across all possible scenarios. Probabilistic models can be manifested as fault or event trees or other system models that use frequency or probability data as input. These models tend to be manifested as computer software, but are not required to do so. Furthermore, the discussion that follows under "Sources of Models" can also be applied to probabilistic models, although it concentrates on deterministic models.

CFD models can provide more accurate predictions than other deterministic models, because they divide a given space into many smaller-volume spaces. However, since they are still models, they are not absolute in their depiction of reality. In addition, they are much more expensive to use, because they are computationally intensive. Because of their expense, complexity, and intensive computational needs, CFD models require much greater scrutiny than do zone models.

It is much easier to assess the sensitivity of different parameters with zone models, because they generally run much faster and the output is much easier to interpret. Prediction of fire growth and spread has a large number of variables associated with it.

Purpose-built models (also known as stand-alone models) are similar to zone models in their ease of use. However, purpose-built models do not provide a comprehensive model. Instead, they predict the value of one variable of interest. For example, such a model can predict the conditions of a ceiling jet at a specified location under a ceiling, but a zone model would "transport" those conditions throughout the enclosure.

Purpose-built models might or might not be manifested as computer software. Models that are not in the form of software are referred to as hand calculations. Purpose-built models are, therefore, simple enough that the data management capabilities of a computer are not necessary. Many of the calculations are found in the *SFPE Handbook of Fire Protection Engineering*.

Types of Evacuation Models. Four categories of evacuation models can be considered: single-parameter estimation methods, movement models, behavioral simulation models, and tenability models.

Single-parameter estimation methods are generally used for simple estimates of movement time. They are usually based on equations derived from observations of movement in nonemergency situations. They can be hand calculations or simple computer models. Examples include calculation methods for flow times based on widths of exit paths and travel times based on travel distances. Sources for these methods include the *SFPE Handbook of Fire Protection Engineering* and the NFPA *Fire Protection Handbook*.

Movement models generally handle large numbers of people in a network flow similar to water in pipes or ball bearings in chutes. They tend to optimize occupant behavior, resulting in predicted evacuation times that can be unrealistic and far from conservative. However, they can be useful in an overall assessment of a design, especially in early evaluation stages where an unacceptable result with this sort of model indicates that the design has failed to achieve the life safety objectives.

Behavioral simulation models take into consideration more of the variables related to occupant movement and behavior. Occupants are treated as individuals and can have unique characteristics assigned to them, allowing a more realistic simulation of the design under consideration. However, given the limited availability of data for the development of these models, for their verification by their authors, or for input when using them, their predictive reliability is questionable.

Tenability Models. In general, tenability models will be needed only to automate calculations for the time-of-exposure effect equations referenced in A.5.2.2.

Other Models. Models can be used to describe combustion (as noted, most fire models only characterize fire effects), automatic system performance, and other elements of the calculation. There are few models in common use for these purposes, so they are not further described here.

Sources of Models. A compendia of computer fire models are found in the *SFPE Computer Software Directory* and in Olenick, S. and Carpenter, D., "An Updated International Survey of Computer Models for Fire and Smoke," *Journal of Fire Protection Engineering*, 13, 2, 2003, pp. 87–110. Within these references are models that were developed by the Building Fire Research Laboratory of the National Institute of Standards and Technology, which can be downloaded from the Internet at http://www.bfrl.nist.gov/864/fmabs.html. Evacuation models are discussed in the *SFPE Handbook of Fire Protection Engineering* and the NFPA *Fire Protection Handbook*.

Verification and validation. Models should undergo verification and validation to ensure that they are appropriate for their intended use. "Verification" is a check of the math used in the models. "Validation" is a check of the physics used in the model. The *SFPE Guidelines for Substantiating a Fire Model for a Given Application* provides a process for verifying and validating models.

The design professional should present the proposal, and the authority having jurisdiction, when deciding whether to approve a proposal, should consider the strength of the evidence presented for the validity, accuracy, relevance, and precision of the proposed methods. An element in establishing the strength of scientific evidence is the extent of external review and acceptance of the evidence by peers of the authors of that evidence.

Models have limitations. Most are not user friendly, and experienced users are able to construct more reasonable models and better interpret output than are novices. For these reasons, the third-party review and equivalency provisions of 5.1.4 and 5.3.3 are provided. The intent is not to discourage the use of models, only to indicate that they should be used with caution by those who are well versed in their nuances.

Input Data. The first step in using a model is to develop the input data. The heat release rate curve specified by the user is the driving force of a fire effects model. If this curve is incorrectly defined, the subsequent results are not usable. In addition to the smoldering and growth phases that will be specified as part of the scenario definition, two additional phases are needed to complete the input heat release rate curve — steady burning and burnout.

Steady burning is characterized by its duration, which is a function of the total amount of fuel available to be burned. In determining the duration of this phase, the designer needs to consider how much fuel has been assumed to be consumed in the smoldering and growth phases and how much is assumed to be consumed in the burnout phase that follows. Depending on the assumptions made regarding the amount of fuel consumed during burnout, the time at which this phase starts is likely to be easy to determine.

The preceding discussion assumes that the burning objects are solid (e.g., tables and chairs). If liquid or gaseous fuels are involved, the shape of the curve will be different. For example, smoldering is not relevant for burning liquids or gases, and the growth period is very short, typically measured in seconds. Peak heat release rate can depend primarily on the rate of release, on the leak rate (gases and liquid sprays), or on the extent of spill (pooled liquids). The steady burning phase is once again dependent on the amount of fuel available to burn. Like the growth phase, the burnout phase is typically short (e.g., closing a valve), although it is conceivable that longer times might be appropriate, depending on the extinguishment scenario.

Material properties are usually needed for all fuel items, both initial and secondary, and the enclosure surfaces of involved rooms or spaces.

For all fires of consequence, it is reasonable to assume that the fire receives adequate ventilation. If there is insufficient oxygen, the fire will not be sustained. An overabundance of oxygen is only a concern in special cases (e.g., hermetically sealed spaces) where a fire might not occur due to dilution of the fuel (i.e., a flammable mixture is not produced). Therefore, given that the scenarios of interest will occur in nonhermetically sealed enclosures, it is reasonable to assume that adequate ventilation is available and that, if a fire starts, it will continue to burn until it either runs out of fuel or is extinguished by other means. The only variable that might need to be assumed is the total vent width.

Maximum fire extent is affected by two geometric aspects: burning object proximity to walls and overall enclosure dimensions.

The room dimensions affect the time required for a room to flashover. For a given amount and type of fuel, under the same ventilation conditions, a small room will flashover before a large room. In a large room with a small amount of fuel, a fire will behave as if it is burning outside — that is, adequate oxygen for burning and no concentration of heat exist. If the fuel package is unchanged but the dimensions of the room are decreased, the room will begin to have an affect on the fire, assuming adequate ventilation. The presence of the relatively smaller enclosure results in the buildup of a hot layer of smoke and other products of combustion under the ceiling. This buildup, in turn, feeds more heat back to the seat of the fire, which results in an increase in the pyrolysis rate of the fuel and, thus, increases the amount of heat energy released by the fire. The room enclosure surfaces themselves also contribute to this radiation feedback effect.

Probabilistic data are expressed as either a frequency (units of inverse time) or a probability (unitless, but applicable to a stated period of time). An example of the former is the expected number of failures per year, and the range of the latter is between zero and one, inclusive. Probabilities can be either objective or subjective. Subjective probabilities express a degree of belief that an event will occur. Objective probabilities are based on historical data and can be expressed as a reliability of an item, such as a component or a system.

A.5.6.3.3 Procedures used to develop required input data need to preserve the intended conservatism of all scenarios and assumptions. Conservatism is only one means to address the uncertainty inherent in calculations and does not eliminate the need to consider safety factors, sensitivity analysis, and other methods of dealing with uncertainty. The *SFPE Guidelines for Substantiating a Fire Model for a Given Application* outlines a process for identifying and treating uncertainty and other inaccuracies introduced through the use of fire models.

A.5.6.4 An assessment method translates input data, which might include test specifications, parameters, or variables for modeling, or other data, into output data, which are measured against the performance criteria. Computer fire models should be evaluated to ensure that they are appropriate for their intended use in accordance with the *SFPE Guidelines for Substantiating a Fire Model for a Given Application.*

A.5.7 The assessment of precision required in 5.8.2 will require a sensitivity and uncertainty analysis, which can be translated into safety factors.

Sensitivity Analysis. The first run a model user makes should be labeled as the base case, using the nominal values of the various input parameters. However, the model user should not rely on a single run as the basis for any performance-based fire safety system design. Ideally, each variable or parameter that the model user made to develop the nominal input data should have multiple runs associated with it, as should combinations of key variables and parameters. Thus, a sensitivity analysis should be conducted that provides the model user with data that indicate how the effects of a real fire might vary and how the response of the proposed fire safety design might also vary.

The interpretation of a model's predictions can be a difficult exercise if the model user does not have knowledge of fire dynamics or human behavior.

Reasonableness Check. The model user should first try to determine whether the predictions actually make sense; that is, whether they do not upset intuition or preconceived expectations. Most likely, if the results do not pass this test, an input error has been committed.

Sometimes the predictions appear to be reasonable but are, in fact, incorrect. For example, a model can predict higher temperatures farther from the fire than closer to it. The values themselves might be reasonable; for example, they are not hotter than the fire, but they do not "flow" down the energy as expected.

A margin of safety can be developed using the results of the sensitivity analysis in conjunction with the performance criteria to provide the possible range of time during which a condition is estimated to occur.

Safety factors and margin of safety are two concepts used to quantify the amount of uncertainty in engineering analyses. Safety factors are used to provide a margin of safety and represent, or address, the gap in knowledge between the theoretically perfect model — reality — and the engineering models that can only partially represent reality.

Safety factors can be applied either to the predicted level of a physical condition or to the time at which the condition is predicted to occur. Thus, a physical or a temporal safety factor, or both, can be applied to any predicted condition. A predicted condition (i.e., a parameter's value) and the time at which it occurs are best represented as distributions. Ideally, a computer fire model predicts the expected or nominal value of the distribution. Safety factors are intended to represent the spread of the distributions.

Given the uncertainty associated with data acquisition and reduction, and the limitations of computer modeling, any condition predicted by a computer model can be thought of as an expected or nominal value within a broader range. For example, an upper layer temperature of 1110°F (600°C) is predicted at a given time. If the modeled scenario is then tested (i.e., full-scale experiment based on the computer model's input data), the actual temperature at that given time could be 1185°F or 1085°F (640°C or 585°C). Therefore, the temperature should be reported as 1110°F + 75°F/–25°F (600°C + 40°C/–15°C) or as a range of 1085°F to 1185°F (585°C to 640°C).

Ideally, predictions are reported as a nominal value, a percentage, or an absolute value. As an example, an upper layer temperature prediction could be reported as "1110°F (600°C), 55°F (30°C)," or "1110°F (600°C), 5 percent." In this case, the physical safety factor is 0.05 (i.e., the amount by which the nominal value should be degraded and enhanced). Given the state-of-the-art of computer fire modeling, this is a very low safety factor. Physical safety factors tend to be on the order of tens of percent. A safety factor of 50 percent is not unheard of.

Part of the problem in establishing safety factors is that it is difficult to state the percentage or range that is appropriate. These values can be obtained when the computer model predictions are compared to test data. However, using computer fire models in a design mode does not facilitate this comparison, due to the following:

(1) The room being analyzed has not been built yet.
(2) Test scenarios do not necessarily depict the intended design.

A sensitivity analysis should be performed, based on the assumptions that affect the condition of interest. A base case that uses all nominal values for input parameters should be developed. The input parameters should be varied over reasonable ranges, and the variation in predicted output should be noted. This output variation can then become the basis for physical safety factors.

The temporal safety factor addresses the issue of when a condition is predicted and is a function of the rate at which processes are expected to occur. If a condition is predicted to occur

2 minutes after the start of the fire, this prediction can be used as a nominal value. A process similar to that already described for physical safety factors can also be employed to develop temporal safety factors. In such a case, however, the rates (e.g., rates of heat release and toxic product generation) will be varied instead of absolute values (e.g., material properties).

The margin of safety can be thought of as a reflection of societal values and can be imposed by the authority having jurisdiction for that purpose. Because the time for which a condition is predicted will most likely be the focus of the authority having jurisdiction (e.g., the model predicts that occupants will have 5 minutes to safely evacuate), the margin of safety will be characterized by temporal aspects and tacitly applied to the physical margin of safety.

Escaping the harmful effects of fire (or mitigating them) is, effectively, a race against time. When assessing fire safety system designs based on computer model predictions, the choice of an acceptable time is important. When an authority having jurisdiction is faced with the predicted time of untenability, a decision needs to be made regarding whether sufficient time is available to ensure the safety of building occupants. The authority having jurisdiction is assessing the margin of safety. Is there sufficient time to get everyone out safely? If the authority having jurisdiction feels that the predicted egress time is too close to the time of untenability, the authority having jurisdiction can impose an additional period of time that the designer will have to incorporate into the system design. In other words, the authority having jurisdiction can impose a greater margin of safety than that originally proposed by the designer.

A.5.8.1 The *SFPE Engineering Guide to Performance-Based Fire Protection* describes the documentation that should be provided for a performance-based design.

Proper documentation of a performance-based design is critical to design acceptance and construction. Proper documentation will also ensure that all parties involved understand the factors necessary for the implementation, maintenance, and continuity of the fire protection design. If attention to details is maintained in the documentation, there should be little dispute during approval, construction, start-up, and use.

Poor documentation could result in rejection of an otherwise good design, poor implementation of the design, inadequate system maintenance and reliability, and an incomplete record for future changes or for testing the design forensically.

A.5.8.2 The sources, methodologies, and data used in performance-based designs should be based on technical references that are widely accepted and used by the appropriate professions and professional groups. This acceptance is often based on documents that are developed, reviewed, and validated under one of the following processes:

(1) Standards developed under an open consensus process conducted by recognized professional societies, codes or standards organizations, or governmental bodies
(2) Technical references that are subject to a peer review process and published in widely recognized peer-reviewed journals, conference reports, or other publications
(3) Resource publications, such as the *SFPE Handbook of Fire Protection Engineering*, which are widely recognized technical sources of information

The following factors are helpful in determining the acceptability of the individual method or source:

(1) Extent of general acceptance in the relevant professional community, including peer-reviewed publication, widespread citation in the technical literature, and adoption by or within a consensus document
(2) Extent of documentation of the method, including the analytical method itself, assumptions, scope, limitations, data sources, and data reduction methods
(3) Extent of validation and analysis of uncertainties, including comparison of the overall method with experimental data to estimate error rates, as well as analysis of the uncertainties of input data, uncertainties and limitations in the analytical method, and uncertainties in the associated performance criteria
(4) Extent to which the method is based on sound scientific principles
(5) Extent to which the proposed application is within the stated scope and limitations of the supporting information, including the range of applicability for which there is documented validation, and considering factors such as spatial dimensions, occupant characteristics, and ambient conditions, which can limit valid applications

In many cases, a method will be built from, and will include, numerous component analyses. Such component analyses should be evaluated using the same acceptability factors that are applied to the overall method, as outlined in items (1) through (5).

A method to address a specific fire safety issue, within documented limitations or validation regimes, might not exist. In such a case, sources and calculation methods can be used outside of their limitations, provided that the design team recognizes the limitations and addresses the resulting implications.

The technical references and methodologies to be used in a performance-based design should be closely evaluated by the design team and the authority having jurisdiction, and possibly by a third-party reviewer. The strength of the technical justification should be judged using criteria in items (1) through (5). This justification can be strengthened by the presence of data obtained from fire testing.

A.5.8.11 Documentation for modeling should conform to ASTM E 1472, *Standard Guide for Documenting Computer Software for Fire Models*, although most, if not all, models were originally developed before this standard was promulgated. Information regarding the use of the model DETACT-QS can be found in the *SFPE Engineering Guide–the Evaluation of the Computer Fire Model DETACT-QS.*

A.6.1.2.1 Assembly occupancies might include the following:

(1) Armories
(2) Assembly halls
(3) Auditoriums
(4) Bowling lanes
(5) Club rooms
(6) College and university classrooms, 50 persons and over
(7) Conference rooms
(8) Courtrooms
(9) Dance halls
(10) Drinking establishments
(11) Exhibition halls
(12) Gymnasiums
(13) Libraries
(14) Mortuary chapels
(15) Motion picture theaters
(16) Museums
(17) Passenger stations and terminals of air, surface, underground, and marine public transportation facilities
(18) Places of religious worship

(19) Pool rooms
(20) Recreation piers
(21) Restaurants
(22) Skating rinks
(23) Special amusement buildings, regardless of occupant load
(24) Theaters

Assembly occupancies are characterized by the presence or potential presence of crowds with attendant panic hazard in case of fire or other emergency. They are generally or occasionally open to the public, and the occupants, who are present voluntarily, are not ordinarily subject to discipline or control. Such buildings are ordinarily not used for sleeping purposes. Special conference rooms, snack areas, and other areas incidental to, and under the control of, the management of other occupancies, such as offices, fall under the 50-person limitation.

Restaurants and drinking establishments with an occupant load of fewer than 50 persons should be classified as mercantile occupancies.

Occupancy of any room or space for assembly purposes by fewer than 50 persons in another occupancy, and incidental to such other occupancy, should be classified as part of the other occupancy and should be subject to the provisions applicable thereto.

For special amusement buildings, see 12.4.8 and 13.4.8.

A.6.1.3.1 Educational occupancies include the following:

(1) Academies
(2) Kindergartens
(3) Schools

An educational occupancy is distinguished from an assembly occupancy in that the same occupants are regularly present.

A.6.1.4.1 Day-care occupancies include the following:

(1) Adult day-care occupancies, except where part of a health care occupancy
(2) Child day-care occupancies
(3) Day-care homes
(4) Kindergarten classes that are incidental to a child day-care occupancy
(5) Nursery schools

In areas where public schools offer only half-day kindergarten programs, many child day-care occupancies offer state-approved kindergarten classes for children who need full-day care. As these classes are normally incidental to the day-care occupancy, the requirements of the day-care occupancy should be followed.

A.6.1.5.1 Health care occupancies include the following:

(1) Hospitals
(2) Limited care facilities
(3) Nursing homes

Occupants of health care occupancies typically have physical or mental illness, disease, or infirmity. They also include infants, convalescents, or infirm aged persons.

A.6.1.6.1 It is not the intent that occupants be considered to be incapable of self-preservation just because they are in a wheelchair or use assistive walking devices, such as a cane, a walker, or crutches. Rather, it is the intent to address emergency care centers that receive patients who have been rendered incapable of self-preservation due to the emergency, such as being rendered unconscious as a result of an accident or being unable to move due to sudden illness.

A.6.1.7.1 Detention and correctional occupancies include the following:

(1) Adult and juvenile substance abuse centers
(2) Adult and juvenile work camps
(3) Adult community residential centers
(4) Adult correctional institutions
(5) Adult local detention facilities
(6) Juvenile community residential centers
(7) Juvenile detention facilities
(8) Juvenile training schools

See A.22.1.1.1.6 and A.23.1.1.1.6.

A.6.1.7.2 Chapters 22 and 23 address the residential housing areas of the detention and correctional occupancy as defined in 3.3.190.5. Examples of uses, other than residential housing, include gymnasiums or industries.

A.6.1.8.1.1 The application statement of 24.1.1.1 limits each dwelling unit to being "occupied by members of a single family with not more than three outsiders." The *Code* does not define the term *family*. The definition of family is subject to federal, state, and local regulations and might not be restricted to a person or a couple (two people) and their children. The following examples aid in differentiating between a single-family dwelling and a lodging or rooming house:

(1) An individual or a couple (two people) who rent a house from a landlord and then sublease space for up to three individuals should be considered a family renting to a maximum of three outsiders, and the house should be regulated as a single-family dwelling in accordance with Chapter 24.
(2) A house rented from a landlord by an individual or a couple (two people) in which space is subleased to 4 or more individuals, but not more than 16, should be considered and regulated as a lodging or rooming house in accordance with Chapter 26.
(3) A residential building that is occupied by 4 or more individuals, but not more than 16, each renting from a landlord, without separate cooking facilities, should be considered and regulated as a lodging or rooming house in accordance with Chapter 26.

A.6.1.8.1.3 So-called apartment hotels should be classified as hotels, because they are potentially subject to the same transient occupancy as hotels. Transients are those who occupy accommodations for less than 30 days.

A.6.1.8.1.4 Rooms within dormitories intended for the use of individuals for combined living and sleeping purposes are guest rooms or guest suites. Examples of dormitories include college dormitories, fraternity and sorority houses, and military barracks.

A.6.1.9.1 The following are examples of facilities classified as residential board and care occupancies:

(1) Group housing arrangement for physically or mentally handicapped persons who normally attend school in the community, attend worship in the community, or otherwise use community facilities
(2) Group housing arrangement for physically or mentally handicapped persons who are undergoing training in preparation for independent living, for paid employment, or for other normal community activities

(3) Group housing arrangement for the elderly that provides personal care services but that does not provide nursing care
(4) Facilities for social rehabilitation, alcoholism, drug abuse, or mental health problems that contain a group housing arrangement and that provide personal care services but do not provide acute care
(5) Assisted living facilities
(6) Other group housing arrangements that provide personal care services but not nursing care

A.6.1.10.1 Mercantile occupancies include the following:

(1) Auction rooms
(2) Department stores
(3) Drugstores
(4) Restaurants with fewer than 50 persons
(5) Shopping centers
(6) Supermarkets

Office, storage, and service facilities incidental to the sale of merchandise and located in the same building should be considered part of the mercantile occupancy classification.

A.6.1.11.1 Business occupancies include the following:

(1) Air traffic control towers (ATCTs)
(2) City halls
(3) College and university instructional buildings, classrooms under 50 persons, and instructional laboratories
(4) Courthouses
(5) Dentists' offices
(6) Doctors' offices
(7) General offices
(8) Outpatient clinics (ambulatory)
(9) Town halls

Doctors' and dentists' offices are included, unless of such character as to be classified as ambulatory health care occupancies. *(See 3.3.190.1.)*

Birth centers should be classified as business occupancies if they are occupied by fewer than four patients, not including infants, at any one time; do not provide sleeping facilities for four or more occupants; and do not provide treatment procedures that render four or more patients, not including infants, incapable of self-preservation at any one time. For birth centers occupied by patients not meeting these parameters, see Chapter 18 or Chapter 19, as appropriate.

Service facilities common to city office buildings, such as newsstands, lunch counters serving fewer than 50 persons, barber shops, and beauty parlors are included in the business occupancy group.

City halls, town halls, and courthouses are included in this occupancy group, insofar as their principal function is the transaction of public business and the keeping of books and records. Insofar as they are used for assembly purposes, they are classified as assembly occupancies.

A.6.1.12.1 Industrial occupancies include the following:

(1) Drycleaning plants
(2) Factories of all kinds
(3) Food processing plants
(4) Gas plants
(5) Hangars (for servicing/maintenance)
(6) Laundries
(7) Power plants
(8) Pumping stations
(9) Refineries
(10) Sawmills
(11) Telephone exchanges

In evaluating the appropriate classification of laboratories, the authority having jurisdiction should treat each case individually, based on the extent and nature of the associated hazards. Some laboratories are classified as occupancies other than industrial; for example, a physical therapy laboratory or a computer laboratory.

A.6.1.13.1 Storage occupancies include the following:

(1) Barns
(2) Bulk oil storage
(3) Cold storage
(4) Freight terminals
(5) Grain elevators
(6) Hangars (for storage only)
(7) Parking structures
(8) Truck and marine terminals
(9) Warehouses

Storage occupancies are characterized by the presence of relatively small numbers of persons in proportion to the area.

A.6.1.14.1.3 Examples of uses that might be incidental to another occupancy include the following:

(1) Newsstand (mercantile) in an office building
(2) Giftshop (mercantile) in a hotel
(3) Small storage area (storage) in any occupancy
(4) Minor office space (business) in any occupancy
(5) Maintenance area (industrial) in any occupancy

A.6.1.14.1.3(2) Examples of uses that have occupant loads below the occupancy classification threshold levels include the following:

(1) Assembly use with fewer than 50 persons within a business occupancy
(2) Educational use with fewer than 6 persons within an apartment building.

A.6.1.14.3.2 For example, a common path of travel that occurs wholly in a business tenant space, in a multiple occupancy building containing assembly and business occupancies, should not have to meet the assembly occupancy common path of travel limitation.

A.6.1.14.4.5 Where the *Code* text states that the provision has applicability to the building, rather than just to the occupancy, the provision applies to the entire building, regardless of whether the separated occupancies form of protection is used. For example, the provision of 18.3.5.1 requires that the entire building housing a health care occupancy be sprinklered. Contrast that with the requirement of 20.3.4.1, which requires an ambulatory health care facility, and not the entire building, to be provided with a fire alarm system.

A.6.2.1.3 Under the provision of 6.2.1.3, any violation of the requirements of Chapters 11 through 42 for separation or protection of hazardous operation or storage would inherently involve violation of the other sections of the *Code*, unless additional egress facilities appropriate to high hazard contents were provided.

A.6.2.2.1 These classifications do not apply to the application of sprinkler protection classifications. See NFPA 13, *Standard for the Installation of Sprinkler Systems*. Depending on the use of the space, the area might require special hazard protection in accordance with Section 8.7.

A.6.2.2.2 Chapter 42 recognizes storage of noncombustible materials as low hazard. In other occupancies, it is assumed that, even where the actual contents hazard is normally low, there is sufficient likelihood that some combustible materials or hazardous operations will be introduced in connection with building repair or maintenance, or some psychological factor might create conditions conducive to panic, so that the egress facilities cannot safely be reduced below those specified for ordinary hazard contents.

A.6.2.2.3 Ordinary hazard classification represents the conditions found in most buildings and is the basis for the general requirements of this *Code*.

The fear of poisonous fumes or explosions is necessarily a relative matter to be determined on a judgment basis. All smoke contains some toxic fire gases but, under conditions of ordinary hazard, there should be no unduly dangerous exposure during the period necessary to escape from the fire area, assuming there are proper exits.

A.6.2.2.4 High hazard contents include occupancies where flammable liquids are handled or used or are stored under conditions involving possible release of flammable vapors; where grain dust, wood flour or plastic dust, aluminum or magnesium dust, or other explosive dusts are produced; where hazardous chemicals or explosives are manufactured, stored, or handled; where materials are processed or handled under conditions producing flammable flyings; and other situations of similar hazard.

Chapters 40 and 42 include detailed provisions on high hazard contents.

A.7.1.1 An installation of supplemental evacuation equipment is not recognized as a means of egress. Consequently, such equipment does not satisfy any requirement for minimum number of, capacity of, travel distance to, or remoteness of, means of egress.

A.7.1.3.2.1(1) In existing buildings, existing walls in good repair and consisting of lath and plaster, gypsum wallboard, or masonry units can usually provide satisfactory protection for the purposes of this requirement where a 1-hour fire resistance rating is required. Further evaluation might be needed where a 2-hour fire resistance rating is required. Additional guidelines can be found in Annex O of NFPA 914, *Code for Fire Protection of Historic Structures*, and in the *SFPE Handbook of Fire Protection Engineering*.

A.7.1.3.2.1(3) In existing buildings, existing walls in good repair and consisting of lath and plaster, gypsum wallboard, or masonry units can usually provide satisfactory protection for the purposes of this requirement where a 1-hour fire resistance rating is required. Further evaluation might be needed where a 2-hour fire resistance rating is required. Additional guidelines can be found in Annex O of NFPA 914, *Code for Fire Protection of Historic Structures*, and in the *SFPE Handbook of Fire Protection Engineering*.

A.7.1.3.2.1(6) It is not the intent to require the structural elements supporting outside stairs, or structural elements that penetrate within exterior walls or any other wall not required to have a fire resistance rating, to be protected by fire resistance–rated construction.

A.7.1.3.2.1(9) Means of egress from the level of exit discharge is permitted to pass through an exit stair enclosure or exit passageway serving other floors. Doors for convenience purposes and unrelated to egress also are permitted to provide access to and from exit stair enclosures and exit passageways, provided that such doors are from corridors or normally occupied spaces. It is also the intent of this provision to prohibit exit enclosure windows, other than approved vision panels in doors, that are not mounted in an exterior wall.

A.7.1.3.2.1(10)(b) Penetrations for electrical wiring are permitted where the wiring serves equipment permitted by the authority having jurisdiction to be located within the exit enclosure, such as security systems, public address systems, and fire department emergency communications devices.

A.7.1.3.2.3 This provision prohibits the use of exit enclosures for storage or for installation of equipment not necessary for safety. Occupancy is prohibited other than for egress, refuge, and access. The intent is that the exit enclosure essentially be "sterile" with respect to fire safety hazards.

A.7.1.4.1 See Chapters 12 through 42 for further limitations on interior wall and ceiling finish.

A.7.1.4.2 See Chapters 12 through 42 for further limitations on interior floor finish.

A.7.1.5 For the purpose of this requirement, projections include devices such as lighting equipment, emergency signaling equipment, environmental controls and equipment, security devices, signs, and decorations that are typically limited in area.

A.7.1.6.4 The foreseeable slip conditions are those that are likely to be present at the location of the walking surface during the use of the building or area. Examples of foreseeable conditions include a swimming pool deck and exterior means of egress, generally, that are likely to be wet.

Regarding the slip resistance of treads, it should be recognized that, when walking up or down stairs, a person's foot exerts a smaller horizontal force against treads than is exerted when walking on level floors. Therefore, materials used for floors that are acceptable as slip resistant (as described by ASTM F 1637, *Standard Practice for Safe Walking Surfaces*) provide adequate slip resistance where used for stair treads. Such slip resistance includes the important leading edges of treads, the part of the tread that the foot first contacts during descent, which is the most critical direction of travel. If stair treads are wet, there is an increased danger of slipping, just as there is an increased danger of slipping on wet floors of similar materials. A small wash or drainage slope on exterior stair treads is, therefore, recommended to shed water. (*See Templer, J. A., The Staircase: Studies of Hazards, Falls, and Safer Design, Cambridge, MA: MIT Press, 1992.*)

A.7.1.7.2 Aside from the problems created for persons who are mobility impaired, small changes of elevations in floors are best avoided because of the increased occurrence of missteps where the presence of single steps, a series of steps, or a ramp is not readily apparent. Although small changes of elevation pose significant fall risks in the case of individual movement, they are even more undesirable where crowds traverse the area.

A contrasting marking stripe on each stepping surface can be helpful at the nosing or leading edge so that the location of each step is readily apparent, especially when viewed in descent. Such stripes should be not less than 1 in. (25 mm), but should not exceed 2 in. (51 mm), in width. Other methods could include a relatively higher level of lighting, contrasting colors, contrasting textures, highly prominent handrails, warning signs, a combination thereof, or other similar means. The construction or application of marking stripes should be such that slip resistance is consistent over the walking surface and no tripping hazard is created *(see also A.7.2.2.3.3.2)*. Depending on the distractions of the surroundings, the familiarity of users with a particular small change of level, and especially the number of people that might be in a group traversing the change of level (thereby reducing visibility of the level changes), a strong argument can be made for the elimination of steps and ramps that might pose a risk of missteps.

A.7.1.8 Elements of the means of egress that might require protection with guards include stairs, landings, escalators, moving walks, balconies, corridors, passageways, floor or roof openings, ramps, aisles, porches, and mezzanines.

Escalators and moving walks, other than previously approved existing escalators and moving walks, are prohibited from serving as components of the required means of egress. Building occupants using the escalator at the time of fire or similar emergency must traverse some portion of the escalator to gain access to a required egress route. For those building occupants using the escalator, such travel along the escalator is part of their means of egress. The requirement that guards be provided at the open side of means of egress that exceed 30 in. (760 mm) above the floor or grade below is meant to be applied to escalators and moving walks.

A.7.1.10.1 A proper means of egress allows unobstructed travel at all times. Any type of barrier including, but not limited to, the accumulations of snow and ice in those climates subject to such accumulations is an impediment to free movement in the means of egress. Another example of an obstruction or impediment to full instant use of means of egress is any security device or system that emits any medium that could obscure a means of egress. It is, however, recognized that obstructions occur on a short-duration basis. In these instances, awareness training should be provided to ensure that blockages are kept to a minimum and procedures are established for the control and monitoring of the area affected.

A.7.2.1.2.1 Figure A.7.2.1.2.1(a) and Figure A.7.2.1.2.1(b) illustrate the method of measuring clear width for doors.

In cases where a chapter requires a door width, for example, of not less than 36 in. (915 mm), this requirement can be met by a door leaf of the minimum specified width if the term *clear width* does not appear as part of the minimum width requirement. A pair of cross-corridor doors subject to such a requirement would be judged under the following criteria:

(1) Each door leaf is required to be not less than 36 in. (915 mm) in width.
(2) The pair of doors is required to provide sufficient, clear, unobstructed width (which will be less than the door leaf width measurement) to handle its assigned occupant load, based on a calculation using the appropriate egress capacity factor in Table 7.3.3.1.

Where swinging doors do not open at least 90 degrees, the clear width of the doorway should be measured between the face of the door and the stop.

It is not the intent to regulate projections above the 6 ft 8 in. (2030 mm) height.

A.7.2.1.2.2 Figure A.7.2.1.2.2(a) and Figure A.7.2.1.2.2(b) illustrate the method of measuring egress capacity width for purposes of calculating door egress capacity.

A.7.2.1.2.3.2(2) A example of a room that is "not required to be accessible to persons with severe mobility impairments" is one that is not required to be accessible by *NFPA 5000*, Chapter 10.

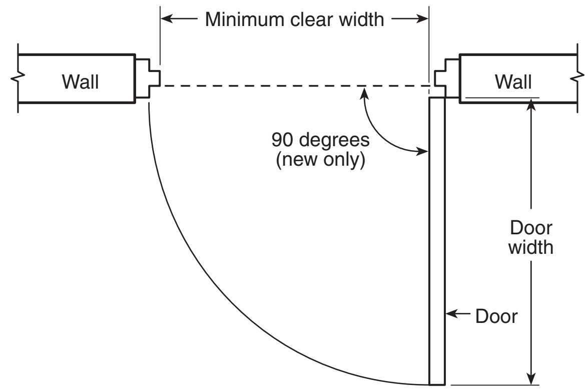

FIGURE A.7.2.1.2.1(a) Minimum Clear Width.

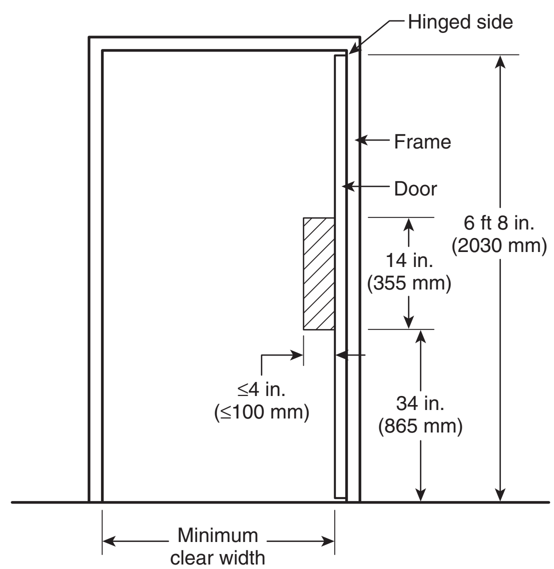

FIGURE A.7.2.1.2.1(b) Minimum Clear Width with Permitted Obstructions.

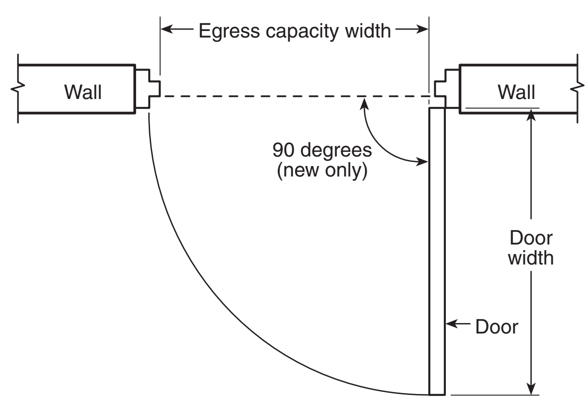

FIGURE A.7.2.1.2.2(a) Door Width — Egress Capacity.

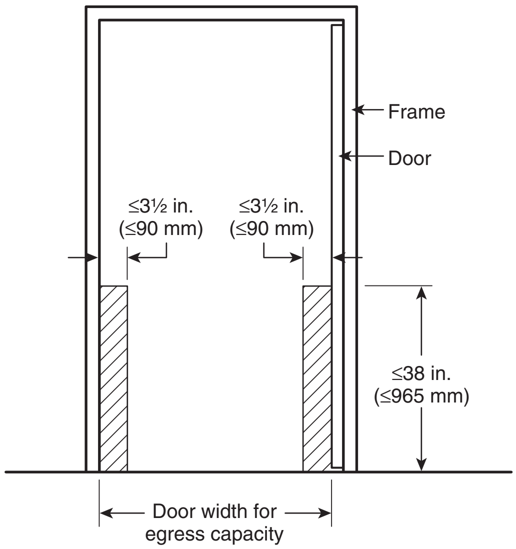

FIGURE A.7.2.1.2.2(b) Door Width — Egress Capacity with Permitted Obstructions.

A.7.2.1.2.3.2(3) A example of a room that is "not required to be accessible to persons with severe mobility impairments" is one that is not required to be accessible by *NFPA 5000*, Chapter 10.

A.7.2.1.2.3.2(9) The relative egress carrying capacity of door openings and stairs is based on the two-to-three ratio used in Table 7.3.3.1 to help balance the capacity of various egress elements and ensure that downstream egress facilities do not form a bottleneck or constriction to flow. For example, a stairway with a nominal width of 56 in. (1420 mm) should be served by an exit discharge door with a minimum width opening of 37 in. (940 mm) if only one discharge door is provided. It might be advantageous for two discharge doors to serve such a stairway, each with a more typical clear opening width of 32 in. (810 mm). This would facilitate access, into the exit, of fire fighters and other emergency responders without causing undue interference to evacuees attempting to transition from the stair to the exit discharge door.

A.7.2.1.4.1 Where doors are subject to two-way traffic, or where their opening can interfere with pedestrian traffic, an appropriately located vision panel can reduce the chance of accidents.

Swinging doors in horizontal- or vertical-rolling partitions should be permitted in a means of egress where the following criteria are met:

(1) The door or doors comply with 7.2.1.4.
(2) The partition in which the doors are mounted complies with the applicable fire protection rating and closes upon smoke detection or power failure at a speed not exceeding 9 in./s (230 mm/s) and not less than 6 in./s (150 mm/s).
(3) The doors mounted in the partition are self-closing or automatic-closing in accordance with 7.2.1.8.

A.7.2.1.4.3 The requirements of 7.2.1.4.3 are not intended to apply to the swing of cross-corridor doors, such as smoke barrier doors and horizontal exits. Neither are the requirements intended to apply to doors from rooms that are typically unoccupied, such as janitor's closets, electrical closets, or telecommunications closets.

A.7.2.1.5.2 Some fire door assemblies are listed for use with fire pins or fusible links that render the door leaf release inoperative upon exposure to elevated temperature during a fire. The door leaf release mechanism is made inoperative where conditions in the vicinity of the door opening become untenable for human occupancy, and such door opening no longer provides a viable egress path.

A.7.2.1.5.5.1 Where the entrance consists of an exterior vestibule, the locking arrangement should be permitted on the egress side of either the interior or exterior door of the vestibule.

A.7.2.1.5.6(5) Separate power supplies might be provided to the electronic lock and the releasing hardware. In this case, it is critical that the lock be arranged to release upon loss of power to the releasing hardware to ensure occupants can egress in the event of a power failure.

A.7.2.1.5.8 It is intended that the re-entry provisions apply only to enclosed exit stairs, not to outside stairs. This arrangement makes it possible to leave the stairway at such floor if the fire renders the lower part of the stair unusable during egress or if the occupants seek refuge on another floor.

A.7.2.1.5.10 Examples of devices that might be arranged to release latches include knobs, levers, and bars. This requirement is permitted to be satisfied by the use of conventional types of hardware, whereby the door is released by turning a lever, knob, or handle or by pushing against a bar, but not by unfamiliar methods of operation, such as a blow to break glass. It is also within the intent of this requirement that switches integral to traditional doorknobs, lever handles, or bars, and that interrupt the power supply to an electromagnetic lock, be permitted, provided that they are affixed to the door leaf. The operating devices should be capable of being operated with one hand and should not require tight grasping, tight pinching, or twisting of the wrist to operate.

A.7.2.1.5.10.3 Examples of devices that, when used with a latch, can be arranged to require not more than one additional releasing operation include night latches, dead bolts, and security chains.

A.7.2.1.5.12 Examples of devices prohibited by this requirement include locks, padlocks, hasps, bars, chains, or combinations thereof.

A.7.2.1.6 None of the special locking arrangements addressed in 7.2.1.6 are intended to allow *credentialed egress, request to exit*, or similar provisions, where an occupant cannot leave the building without swiping a card through a reader. Where such an arrangement is desired to keep track of occupants, the swiping of cards needs to be procedural but not necessary for releasing the door lock or latch. Free egress needs to be available at all times. Another option to free egress is the use of a delayed-egress locking system.

A.7.2.1.6.1.1(3) It is not the intent to require a direct physical or electrical connection between the door release device and the lock. It is the intent to allow door movement initiated by operating the door release device required in 7.2.1.5.10 as one option to initiate the irreversible process.

Several factors need to be considered in approving an increase in delay time from 15 seconds to 30 seconds. Some of the factors include occupancy, occupant density, ceiling height, fire hazards present, fire protection features provided, and the location of the delayed-egress locks. An example of a location where the increase in delay time might not be approved is at an exit stair discharge door.

A.7.2.1.6.1.1(4) In the event that the authority having jurisdiction has permitted increased operation time, the sign should reflect the appropriate time.

A.7.2.1.6.2 It is not the intent to require doors that restrict access but that comply with 7.2.1.5.10 to comply with the access-controlled egress door provisions of 7.2.1.6.2. The term *access-controlled* was chosen when the requirements of 7.2.1.6.2 were first added to the *Code* to describe the function in which a door is electronically locked from the inside in a manner that restricts egress. It is not the *Code's* intent to prohibit methods of securing the door in a locked position from the outside with access control products, provided that the egress requirements of 7.2.1.6.2 are met.

A.7.2.1.6.3(14) It is not the intent to prohibit elevator lobby doors from being equipped with card access systems for gaining access, for example, to tenant spaces. It is the access-controlled egress door system described in 7.2.1.6.2 that is prohibited from being installed on the same door as the lock addressed by 7.2.1.6.3.

A.7.2.1.7.2 The presence of fire exit hardware on a door does not imply the door is required to be a fire protection–rated door.

A.7.2.1.8.1 Examples of doors designed to normally be kept closed include those to a stair enclosure or horizontal exit.

A.7.2.1.9 Special-purpose horizontally sliding accordion or folding door assemblies installed in accordance with 7.2.1.14 should not be considered powered doors subject to the provisions of 7.2.1.9.

Powered doors are divided into two categories — power assisted and power operated. Power-assisted doors that conform to ANSI/BHMA A156.19, *American National Standard for Power Assist and Low Energy Power Operated Doors*, use limited power to operate the door. They require fewer safeguards as compared to full power–operated doors. These door operators are for swinging doors only. Power-operated doors that conform to ANSI/BHMA A156.10, *American National Standard for Power Operated Pedestrian Doors*, require more power to operate the door and require additional safeguards to provide protection against personal injury. Power-operated doors can be swinging, sliding, or folding doors.

A.7.2.1.9.1 An example of the type of door addressed by 7.2.1.9.1 is one actuated by a motion-sensing device upon the approach of a person.

A.7.2.1.9.1.5 Although a single power-operated door leaf located within a two-leaf opening might alone not provide more than 30 in. (760 mm) of clear width in the emergency breakout mode, where both leaves are broken out to become side hinged, the required egress width is permitted to be provided by the width of the entire opening.

A.7.2.1.11.1.3 Security access turnstiles are designed to control security access into and out of buildings. Security access turnstiles might utilize physical barriers consisting of arms, wings, gates, or panels. The subject physical barriers come in various heights and function by retracting or opening in the direction of travel.

A.7.2.1.15.1 Door assemblies within the required means of egress (e.g., door assemblies that discharge from exit enclosures) require a higher level of care and maintenance throughout the life of their installations to ensure they perform as intended by the *Code*. Annual inspection and functional testing of these door assemblies is necessary to verify that they are maintained in proper working condition. Panic hardware and fire exit hardware devices are specifically required to be used in assembly and educational occupancies. However, door leaves that are equipped with panic hardware or fire exit hardware, in areas not specifically required by the *Code* (e.g., stairwell entry doors and double-egress cross-corridor door assemblies not serving an assembly occupancy), should be subject to annual inspection and functional testing to ensure that the operating hardware functions correctly in accordance with 7.2.1.7, since the presence of panic hardware and fire exit hardware implies it is required by the *Code*.

Additionally, door assemblies that are electrically controlled egress doors in accordance with 7.2.1.5.5 and door assemblies that are equipped with special locking arrangements in accordance with 7.2.1.6 are outfitted with electrified hardware and access control devices that are susceptible to wear and abuse. Consequently, these door assemblies need to be inspected and tested on an annual basis, regardless of the occupant load being served.

In cases where the authority having jurisdiction determines there is a distinct hazard to building occupant safety, the inspection requirements of 7.2.1.15 should be applied to other exit access, exit, and exit discharge door assemblies.

A.7.2.1.15.2 See NFPA 80, *Standard for Fire Doors and Other Opening Protectives*, Annex J, for information pertaining to performance-based inspection, testing, and maintenance of door assemblies.

A.7.2.1.15.7 Performing corrective action work on door assemblies frequently requires ordering replacement components that might take time to produce, ship, and install. Consideration of the time it takes to procure and install components should be included in the timeline for restoring the door assemblies to normal working condition.

A.7.2.2.2.1.1(2) It is the intent of 7.2.2.2.1.1(2) to permit the use of Table 7.2.2.2.1.1(b) in existing buildings, even where there is a change in occupancy per 4.6.11. Safety improvements should be made that are reasonable and feasible at minimal cost. Improvements include removal, repair, or replacement of step coverings, as described in A.7.2.2.3.5, particularly Figure A.7.2.2.3.5(e), and addition of functional handrails and guardrails in place of, or in conjunction with, other rails, as described in 7.2.2.4.

A.7.2.2.2.1.2 In some cases, the egress capacity provisions of 7.3.3 will require a stair to have a greater width than the minimum specified in 7.2.2.2.1.2(B).

A.7.2.2.2.1.2(B) The stair width requirement of 7.2.2.2.1.2(B) is based on accumulating the occupant load on each story the stair serves.

The accumulating of occupant load is done for the purposes of the requirements of 7.2.2.2.1.2 only. The egress capacity requirements of Section 7.3 are NOT cumulative on a story-by-story basis.

If additional exits provide egress capacity, the occupant load served by such additional exits, up to the limit permitted for the egress capacity of such additional exits, is not added to the total occupant load considered for the minimum stair width requirements of 7.2.2.2.1.2.

If horizontal exits are provided on any of the stories, the total occupant load of all compartments on the story with the horizontal exits is used in the calculation of the minimum stair width requirements of 7.2.2.2.1.2. The number of stairs permitted through application of horizontal exit requirements in

7.2.4 is not affected by the minimum stair width requirements of 7.2.2.2.1.2.

The examples that follow illustrate applications of the minimum stair width requirement.

A stair in a building two stories in height above grade plane that has 2000 persons on the second story, among 10 equally sized stairs that serve the second story, would be considered to have an occupant load of 200 persons for the purposes of applying Table 7.2.2.2.1.2(B). The minimum width of such a stair would be 44 in. (1120 mm).

For a building with a relatively large floor area, a typical 44 in. (1120 mm) stair would not be required to be increased in width until it serves a building approximately 14 stories in height above grade plane, calculated as follows:

[A.7.2.2.2.1.2(B)]

$$\frac{2000 \text{ persons}}{\text{147 persons per floor for a 44 in. (1120 mm) width stair}} \approx 14 \text{ stories}$$

For egress in the descending direction, only the stair width below the 14 stories with the total occupant load of 2000 persons per stair, or 4000 persons if served by two equally sized stairs, would need to be increased to 56 in. (1420 mm). If the building is 20 stories in height above grade plane, only the stairs on the lowest 7 stories would be required to have the 56 in. (1420 mm) width.

For a building 41 stories in height above grade plane with 200 persons on each story (or 8000 persons overall, not including the level of exit discharge), with two equally sized stairs, each stair would be considered to have an occupant load of 4000 persons for the purposes of applying Table 7.2.2.2.1.2(B). Only the portion of the stair serving 2000 persons would be required to have the wider width. If each story provides the same floor area for occupancy, the upper 20 stories would have 44 in. (1120 mm) stairs, and the lowest 20 stories would have the 56 in. (1420 mm) stairs, as a minimum.

A.7.2.2.2.4 If properly designed and constructed, stairs with winders are not necessarily more dangerous than other stairs. Attention to the factors that follow helps to make winders generally more effective for egress and safety. Handrails should be continuous, without breaks at newel posts, from story to story. Handrails located at a greater than normal distance from the inner turn of winders can improve safety by constraining stair users to walk on the portion of the treads providing deeper treads, which should have not less than 11 in. (280 mm) of depth. Combinations of straight flights and winders are best arranged with winders located only below the straight flight. This arrangement is best because the winders provide larger tread dimensions over much of their width than do typical treads on straight flights. A descending person will, thus, be unlikely to experience a reduction of tread depth during descent, a condition of nonuniformity that is best avoided.

A.7.2.2.3.3.2 The tripping hazard referred to in 7.2.2.3.3.2 occurs especially during descent, where the tread walking surface has projections such as strips of high-friction materials or lips from metal pan stairs that are not completely filled with concrete or other material. In addition, the installation of a retrofit, surface-mounted stair nosing or a strip of high-friction material onto an existing stair tread might produce a projection that creates a tripping hazard. For example, the slight elevation difference between the new stair tread nosing and the stair tread might create enough of an elevation change to trip the stair user. Tread nosings that project over adjacent treads can also be a tripping hazard. ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities*, illustrates projecting nosing configurations that minimize the hazard.

A.7.2.2.3.3.3 "Consistent surface traction" means that slip resistance is reasonably uniform and adequate to minimize risk of slipping across the treads where users' feet contact the tread surface.

For the front-to-back direction, particular attention should be given to consistency of slip resistance in the front two-thirds of the tread, but preferably the entire tread surface. For descent, initial foot contact occurs at the nosing; for ascent, it occurs in the middle of the tread.

For the side-to-side direction, particular attention should be given to consistency of slip resistance within the clear width of the stair between handrails, especially on the portion contacted by users' feet. For most users, this will extend to within about 6 in. (150 mm), measured horizontally, of the handrails; however, some vulnerable stair users might place the front portions of their feet below the handrails.

Consistency is important because misleading user expectation of underfoot conditions is a major factor in missteps and falls involving slipping.

Regarding the slip resistance of treads, it should be recognized that, when walking up or down stairs, a person's foot exerts a smaller horizontal force against treads than is exerted when walking on level floors, including on landings. Therefore, materials used for floors that are acceptable as slip resistant (as described by ASTM F 1637, *Standard Practice for Safe Walking Surfaces* and standards specifically addressing tribology, including ANSI/ASSE A1264.2, *Standard for the Provision of Slip Resistance on Walking/Working Surfaces*) provide adequate slip resistance where used for stair treads. Such slip resistance includes the important leading edges of treads, the part of the tread that the foot first contacts during descent, which is the most critical direction of travel. If stair treads are wet, there is an increased danger of slipping, just as there is an increased danger of slipping on wet floors of similar materials. A small wash or drainage slope on exterior stair treads is, therefore, recommended to shed water. *(See Templer, J. A., The Staircase: Studies of Hazards, Falls, and Safer Design, Cambridge, MA: MIT Press, 1992.)*

A.7.2.2.3.4 A small drainage slope for stair treads subject to wetting can improve tread slip resistance *(see also A.7.2.2.3.3.2)*. A consistent slope to a side of the stair, where drainage is possible, might be preferable to a front-to-back slope of the treads. Providing a pitch of ⅛ in./ft to ¼ in./ft (10 mm/m to 21 mm/m) aids the shedding of water from a nominally horizontal surface.

A.7.2.2.3.5 Figure A.7.2.2.3.5(a), Figure A.7.2.2.3.5(b), Figure A.7.2.2.3.5(c), and Figure A.7.2.2.3.5(d) illustrate the method for measuring riser height and tread depth. Stairs that are covered with resilient floor coverings might need additional tread depth beyond the minimum specified in the *Code*. Any horizontal projection of resilient covering materials beyond the tread nosing and riser, such as carpet and underlayment, can interfere with users' feet and thereby reduce usable tread depth. At the tread nosing, such resilient covering materials might not be capable of providing stable support for users' feet. Generally, effective tread depth is reduced by the uncompressed thickness of such resilient coverings, and might be further reduced over time if coverings are not well secured, and, consequently, might move forward at the nosings. *[See Figure A.7.2.2.3.5(e).]*

FIGURE A.7.2.2.3.5(c) Tread Depth.

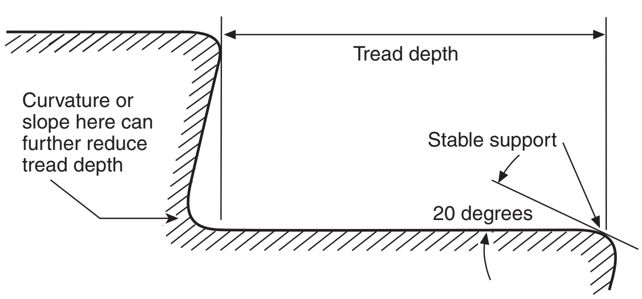

FIGURE A.7.2.2.3.5(d) Tread Measurement with Stable Support at Leading Edge.

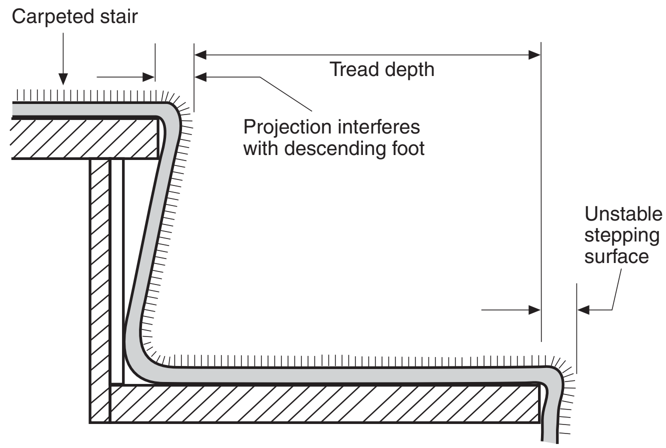

FIGURE A.7.2.2.3.5(e) Tread Measurement with Unstable Stepping Surface at Leading Edge.

A.7.2.2.3.6 A relatively common error in much of home stair construction and, more rarely, in other stair construction is a failure to make the landing nosing projection consistent with the projection of all other nosings in the stair flight. Such an error can easily occur if the stair flight is installed as a prefabricated unit where the top landing does not have a comparable nosing and the unit includes nosing projections. This heightens the risk of an overstepping misstep, at the second or third step down, by a person who is descending.

A fairly reliable test of step dimension uniformity is the crouch and sight test, in which the inspector crouches on the landing above a flight of stairs to confirm that all of the nosings, including the landing nosing, line up. Unless there is a rare matched variation in the height of a step riser and in the tread depth, both proportionally larger or smaller than other steps in the flight, such that the internosing slope or pitch is maintained consistent in the flight, the visual alignment of the nosings in the crouch and sight test will indicate dimensional uniformity. Thus, as a first task in any stair inspection, the crouch and sight test should be routinely performed. If the stair does not pass this visual test, careful measurements performed in accordance with 7.2.2.3.5 are essential. If the stair appears to pass this test, indicating that the internosing slope or pitch is consistent, a prudent second, quick test is to measure the internosing distances for each step to confirm their consistency.

Step dimensions or their uniformity should not be measured by simply laying a measuring tape or stick on the tread or against the riser. Such measurements could be misleading and erroneous relative to the criteria set out in 7.2.2.3.5, particularly if nosing projections are not uniform (as addressed in 7.2.2.3.6.5), if treads slope, or if the slopes vary within a stair flight.

A.7.2.2.3.6.5 "Safety yellow" is the widely used, standard color (described in ANSI/NEMA Z535.1, *Standard for Safety Colors*) to be used for a "caution" function, as a solid color or in alternating, angled yellow-black bars or other geometric combination that draws attention beyond merely designating a nosing. Other nosings, not located above nonuniform risers, need only contrast with the remainder of the step and can be of any color providing contrast relative to the remainder of the tread. Note that similar specification of distinctive and contrasting nosing markings is called for in assembly seating aisle stairs *(see, respectively, 12.2.5.6.6(7) and 12.2.5.6.10.1).* The safety problems of exterior stairs in assembly aisles and adjacent to a sloping public way are similar, as each individual step has to be visually detected in a reliable fashion. In addition, the presence and location of steps with unavoidably nonuniform risers must be effectively communicated, especially when viewed in the descent direction. Widely varying light conditions further heighten the need for such markings.

A.7.2.2.4.1.4 The intent of this provision is to place handrails for the required egress width only, regardless of the actual width. The required egress width is provided along the natural path of travel to and from the building. Examples of this requirement are shown in Figure A.7.2.2.4.1.4. The reduced intermediate handrail spacing of 60 in. (1525 mm), along with a handrail height within the permissible height limits, allows users to reach and grasp one handrail. Except as noted in 7.2.2.4.2 and 7.2.2.4.4, handrails are not required on stair landings.

A.7.2.2.4.5 Figure A.7.2.2.4.5 illustrates some of the requirements of 7.2.2.4.4.

A.7.2.2.4.5.4 Additional handrails, beyond those required by the *Code*, are permitted at heights other than those stipulated. For example, where children under the age of five are major users of a facility, an additional handrail at a height in the range of 28 in. to 32 in. (710 mm to 810 mm) might be useful. Generally, children prefer to use, and can effectively use, handrails that are located at shoulder to head height due to their developmental characteristics and their less developed balance and walking abilities. At age 3, head height ranges from 35 in. to 40 in. (890 mm to 1015 mm); shoulder height averages 29 in. (735 mm). At age 5, head height ranges from 39 in. to 46 in. (990 mm to 1170 mm); shoulder height ranges from 31 in. to 37 in. (785 mm to 940 mm).

A.7.2.2.4.5.6(2) Handrails should be designed so they can be grasped firmly with a comfortable grip and so the hand can be slid along the rail without encountering obstructions. The profile of the rail should comfortably match the hand grips. For example, a round profile, such as is provided by the simplest round tubing or pipe having an outside diameter of 1½ in. to 2 in. (38 mm to 51 mm), provides good graspability for adults. Factors such as the use of a handrail by small children and the wall-fixing details should be taken into account in assessing handrail graspability. The most functional, as well as the most preferred, handrail shape and size is circular with a 1½ in. (38 mm) outside diameter (according to research conducted using adults). Handrails used predominantly by children should be designed at the lower end of the permitted dimensional range.

Handrails are one of the most important components of a stair; therefore, design excesses such as oversized wood handrail sections should be avoided, unless there is a readily perceived and easily grasped handhold provided. In handrail design, it is useful to remember at all times the effectiveness of a simple round profile that allows some locking action by fingers as they curl around and under the handrail.

Perimeter dimension, referred to in 7.2.2.4.5.6(2), is the length of the shortest loop that wraps completely around the railing.

A.7.2.2.4.6.2(3) This reduction in required height applies only to the stair, not to the landings.

A.7.2.2.4.6.3 Vertical intermediate rails are preferred to reduce climbability.

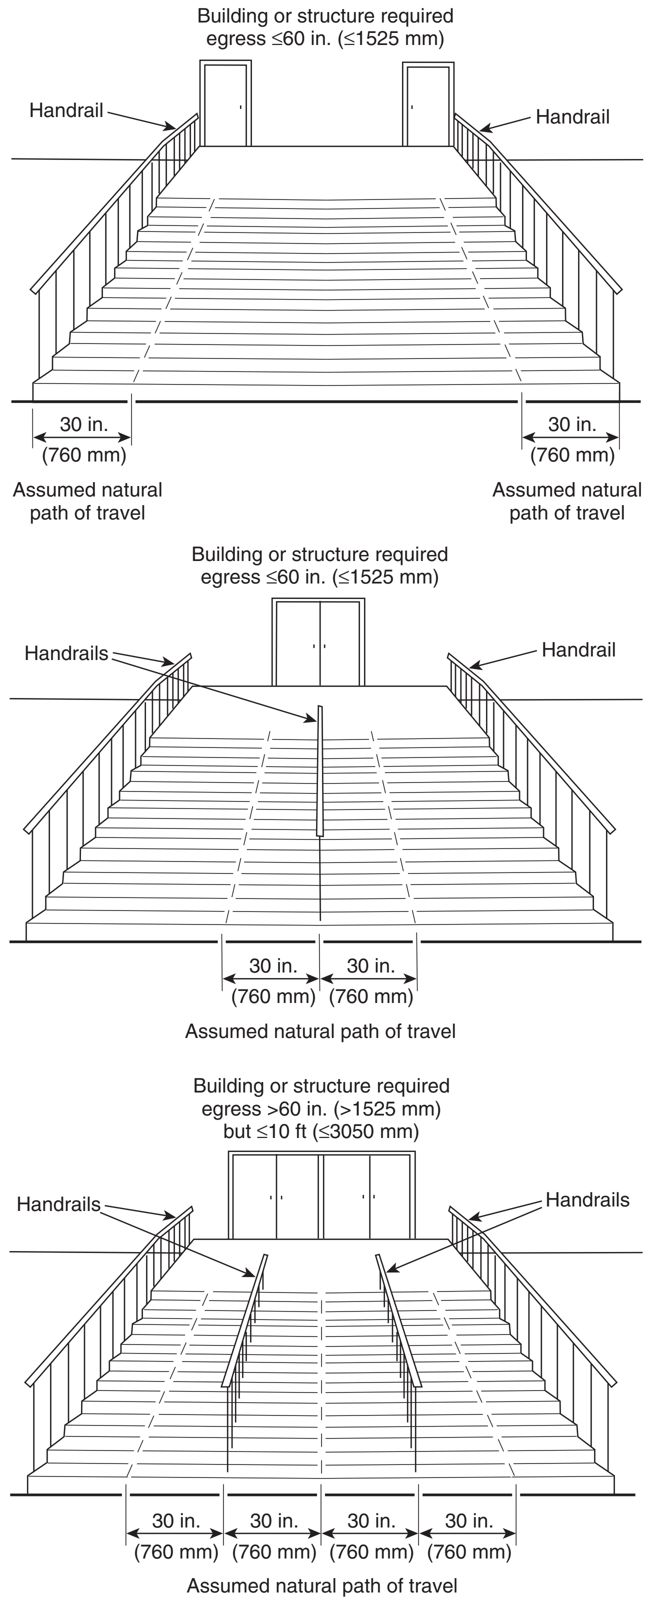

FIGURE A.7.2.2.4.1.4 Assumed Natural Paths of Travel on Monumental Stairs with Various Handrail Locations.

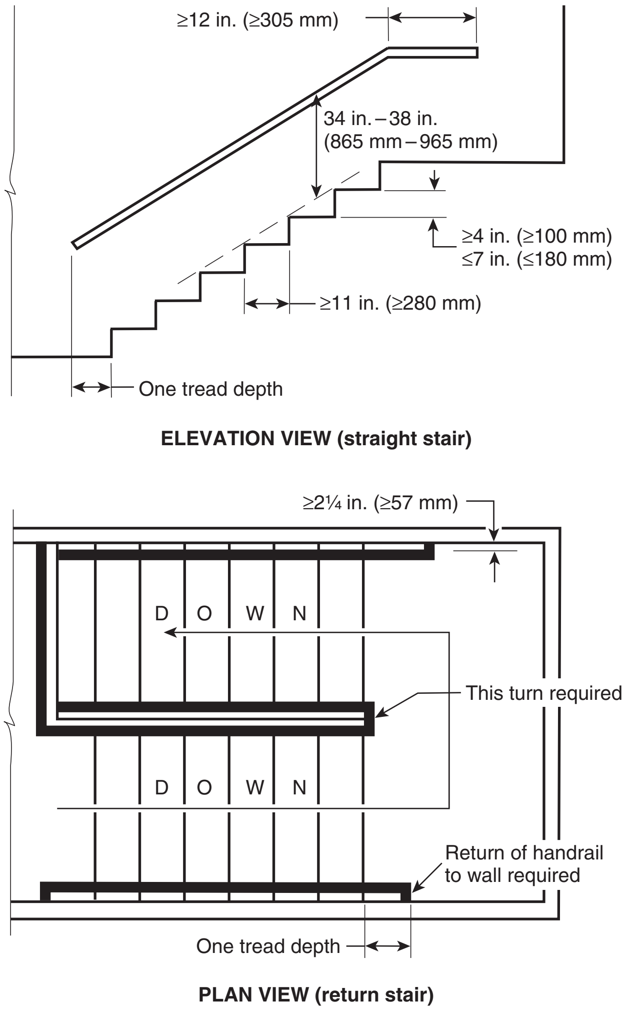

FIGURE A.7.2.2.4.5 Handrail Details.

A.7.2.2.5.2 The purpose of this provision is to protect the exterior wall of a stairway from fires in other portions of the building. If the exterior wall of the stair is flush with the building exterior wall, the fire would need to travel around 180 degrees in order to impact the stair. This has not been a problem in existing buildings, so no protection is required. However, if the angle of exposure is less than 180 degrees, protection of either the stair wall or building wall is required.

Figure A.7.2.2.5.2(a), Figure A.7.2.2.5.2(b), and Figure A.7.2.2.5.2(c) illustrate the requirement, assuming nonrated glass on the exterior wall of the stair is used.

A.7.2.2.5.3 An example of a use with the potential to interfere with egress is storage.

A.7.2.2.5.4 Figure A.7.2.2.5.4 shows an example of a stairway marking sign.

A.7.2.2.5.4.1(M) It is not the intent to require a sign that reads ROOF ACCESS, as such message might be misinterpreted by building occupants as an alternative egress route. However signs that read ROOF ACCESS are not prohibited, as many such signs have been installed in existing buildings so as to make a requirement for removal impractical. Historically, the ROOF ACCESS sign has provided information for the fire

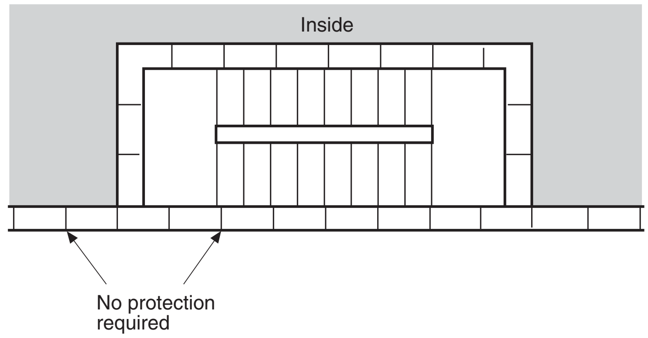

FIGURE A.7.2.2.5.2(a) Stairway with Nonrated Exterior Wall in Same Plane as Building Exterior Wall.

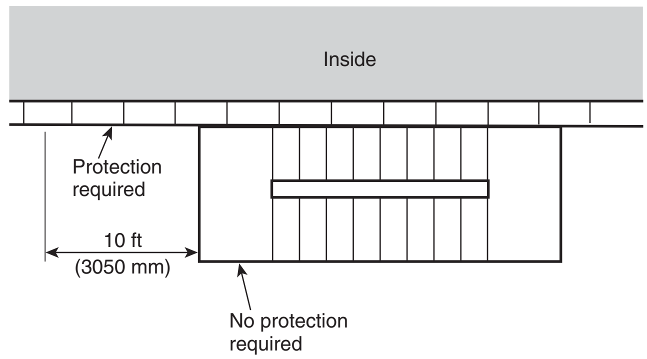

FIGURE A.7.2.2.5.2(b) Stairway with Unprotected Exterior Perimeter Protruding Past Building Exterior Wall.

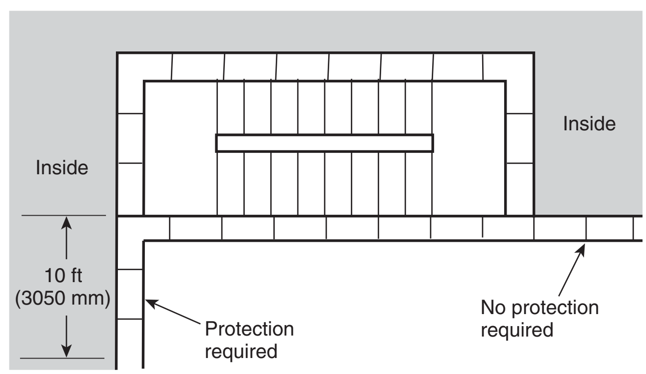

FIGURE A.7.2.2.5.2(c) Stairway with Nonrated Exterior Wall Exposed by Adjacent Exterior Wall of Building.

department. Where there is no roof access, such information will be posted via a NO ROOF ACCESS sign. The absence of the NO ROOF ACCESS sign should be understood by the fire department to mean that roof access is possible.

A.7.2.2.5.4.3 Where environmental conditions (such as illumination levels and directionality or a complex visual field that draws a person's attention away from stair treads) lead to a hazardous reduction in one's ability to perceive stair treads, they should be made of a material that allows ready discrimination of the number and position of treads. In all cases, the

FIGURE A.7.2.2.5.4 Example of a Stairway Marking Sign.

leading edges of all treads should be readily visible during both ascent and descent. A major factor in injury-producing stair accidents, and in the ability to use stairs efficiently in conditions such as egress, is the clarity of the stair treads as separate stepping surfaces.

For stair nosing marking, surface-applied material, such as adhesive-backed tape and magnetic strips, should not be used, as it is not durable under the scuffing from users' feet and, in coming loose, it creates a tripping hazard. While a carefully applied and consistently maintained coating is acceptable, contrasting color or photoluminescent material integral with the nosings is preferable because of its permanence. It is also the intent of 7.2.2.5.4.3 to require the contrasting stairway tread marking to be a material integral with the stair tread and not a material integral with a stair nosing product that is installed on the stair tread. See also 7.1.6.4 and 7.2.2.3.6 for slip resistance uniformity requirements, as well as prohibition of projections on the treads.

Guidance on the use of photoluminescent marking is provided by ASTM E 2030, Standard *Guide for Recommended Uses of Photoluminescent (Phosphorescent) Safety Markings*. Additional marking, for example, at the side boundaries of the stair, should be applied in accordance with the guidance provided therein.

A.7.2.2.5.4.4 Coatings and other applied markings, if used, should be durable for the expected usage, especially at end terminations of the marking and at changes in stair direction where usage is more extensive and hand forces are larger.

A.7.2.2.5.5.1 Exit stair treads are required to incorporate a marking stripe that is applied as a paint/coating or be a material that is integral with the nosing of each step. It is the intent of this provision to require the contrasting stairway tread marking to be a material integral with the stair tread and not a material integral with a stair nosing product that is installed on the stair tread. See also 7.1.6.4 and 7.2.2.3.6 for slip resistance requirements, as well as 7.2.2.3.3.2, which prohibits tread projections.

A.7.2.2.5.5.5 Examples of obstacles addressed by 7.2.2.5.5.5 are standpipes, hose cabinets, and wall projections.

A.7.2.2.5.5.7(B)(1) The marking stripe for door hardware should be of sufficient size to adequately mark the door hardware. This marking could be located behind, immediately adjacent to, or on the door handle or escutcheon.

A.7.2.2.6.2 The guards that are required by 7.1.8 and detailed in 7.2.2.4.5 will usually meet this requirement where the stair is not more than 36 ft (11 m) above the finished ground level. Special architectural treatment, including application of such devices as metal or masonry screens and grilles, will usually be necessary to comply with the intent of this requirement for stairs over 36 ft (11 m) above the finished ground level.

A.7.2.2.6.3.1 Where outside stairs are not required to be separated from interior portions of the building in accordance with 7.2.2.6.3.1(1) through (5), such stairs are considered exits and not exit access.

A.7.2.2.6.5 See A.7.2.2.3.4.

A.7.2.3.9.1 The design pressure differences required by 7.2.3.9.1 are based on specific gas temperatures and ceiling heights. The system is required to be approved, because anticipated conditions might be different from those on which the design pressure differences were calculated and, thus, different design pressure differences might be needed. For additional information on necessary minimum design pressure differences, including calculational techniques, or maximum pressure differences across doors to ensure reasonable operating forces, see NFPA 92, *Standard for Smoke Control Systems.*

A.7.2.4.1.2 An example of one way to provide the required egress capacity from the upper floor of a department store building measuring 350 ft × 200 ft (107 m × 61 m), with an occupant load of 1166 per floor, would be to furnish eight 44 in. (1120 mm) stairs. *[See Figure A.7.2.4.1.2(a).]*

The building is assumed to be divided into two sections by a fire barrier meeting the requirements for a horizontal exit, one 130 ft × 200 ft (40 m × 61 m), and the other 220 ft × 200 ft (67 m × 61 m), with two pairs of 46 in. (1170 mm) double egress doors, with each door providing 44 in. (1120 mm) of clear egress width *[see Figure A.7.2.4.1.2(b)]*. The smaller section, considered separately, will require the equivalent of three 44 in. (1120 mm) exit stairs, and the larger section will require five such exits. The horizontal exits will serve as one of the three exits required for the smaller section and two of the five exits required for the larger section. Therefore, only two 44 in. (1120 mm) exit stairs from the smaller section and three 44 in. (1120 mm) exit stairs from the larger section will be required if the exits can be arranged to meet the requirements for the 150 ft (46 m) travel distance permitted from any point in a nonsprinklered building. Thus, the total number of exit stairs required for the building will be five, as compared to eight if no horizontal exit had been provided.

Another option would be the use of two 56 in. (1420 mm) exit stairs from the larger section, which would reduce the total number of stairways required from the floor to four *[see Figure A.7.2.4.1.2(c)]*. However, if the building were further subdivided by a second fire wall meeting the requirements for a horizontal exit, no further reduction in stairways would be permitted in order to comply with the requirement that horizontal exits provide a maximum of one-half of egress capacity.

It is not the intent of 7.2.4.1.2 to limit the number of doors in the fire barrier forming the horizontal exit. Where doors other than those serving as horizontal exits are provided, such doors are permitted to be considered as part of the exit access and not as exits.

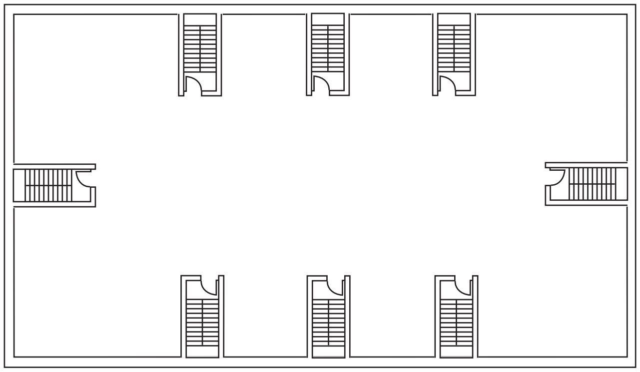

FIGURE A.7.2.4.1.2(a) Eight Exits, Required to Provide Necessary Egress Capacity, with None via Horizontal Exit.

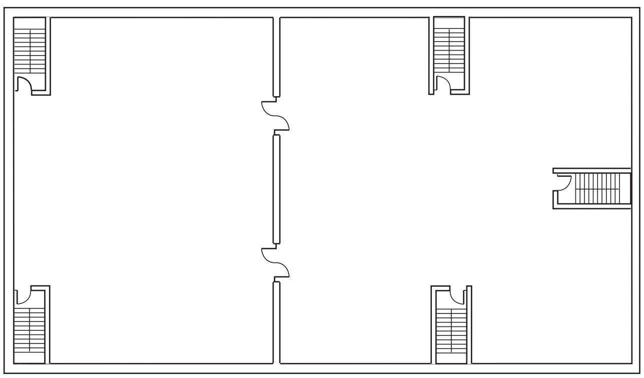

FIGURE A.7.2.4.1.2(b) Number of Stairs Reduced by Three Through Use of Two Horizontal Exits; Egress Capacity Not Reduced.

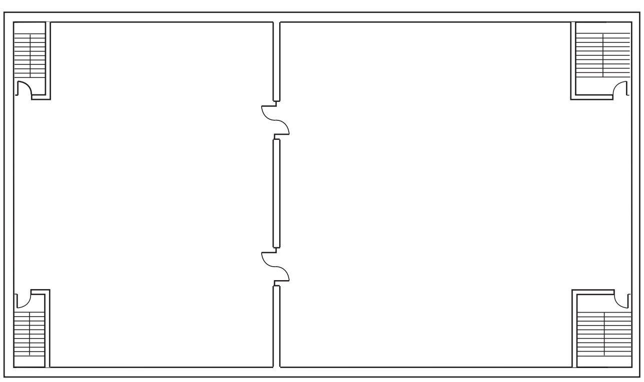

FIGURE A.7.2.4.1.2(c) Number of Stairs Further Reduced by Widening Stairs in Larger Compartment, But Not to Less than One-Half the Required Number and Capacity of Exits from That Compartment.

A.7.2.4.3.1 The continuity requirement of 7.2.4.3.1 does not prohibit the horizontal exit fire barrier from being offset on various floors. Where the floor assembly has a minimum 2-hour fire resistance rating and horizontal exit fire barrier walls are provided on all floors to the finished ground level, the continuity provision might be achieved by a combination of horizontal and vertical assemblies. For requirements regarding the alignment of fire barriers separating buildings of differing construction types, see 8.2.1.3.

A.7.2.4.3.2 Figure A.7.2.4.3.2 depicts an example of the use of the exemption provided by 7.2.4.3.2.

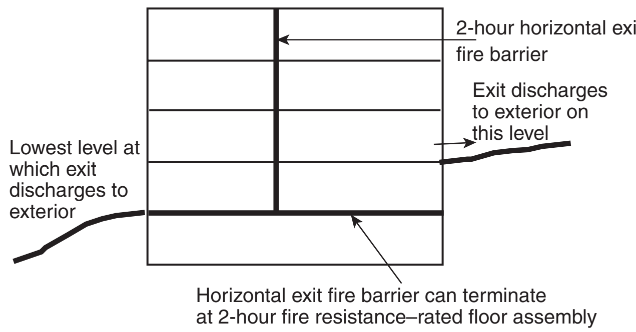

FIGURE A.7.2.4.3.2 Example of Horizontal Exit Termination.

A.7.2.4.3.5 The requirements of 7.2.4.3.5 are meant to apply to the horizontal and vertical portions of the fire barrier forming the horizontal exit.

A.7.2.4.3.10 Fusible link–actuated automatic-closing doors do not qualify for use in horizontal exits under these provisions, because smoke might pass through the opening before there is sufficient heat to release the hold-open device. Such doors are also objectionable because, once closed, they are difficult to open and would inhibit orderly egress.

A.7.2.5.7.1 The guards required by 7.1.8 and detailed in 7.2.2.4.5 for the unenclosed sides of ramps will usually meet this requirement where the ramp is not more than 36 ft (11 m) above the finished ground level. Special architectural treatment, including application of such devices as metal or masonry screens and grilles, will usually be necessary to comply with the intent of the requirements for ramps over 36 ft (11 m) above the finished ground level.

A.7.2.5.7.2 Providing a pitch of ⅛ in./ft to ¼ in./ft (10 mm/m to 21 mm/m) will aid the shedding of water from a nominally horizontal surface.

A.7.2.6 An exit passageway serves as a horizontal means of exit travel that is protected from fire in a manner similar to an enclosed interior exit stair. Where it is desired to offset exit stairs in a multistory building, an exit passageway can be used to preserve the continuity of the protected exit by connecting the bottom of one stair to the top of the stair that continues to the street floor. Probably the most important use of an exit passageway is to satisfy the requirement that at least 50 percent of the exit stairs discharge directly outside from multistory buildings *(see 7.7.2)*. Thus, if it is impractical to locate the stair on an exterior wall, an exit passageway can be connected to the bottom of the stair to convey the occupants safely to an outside exit door. In buildings of extremely large area, such as shopping malls and some factories, the exit passageway can be used to advantage where the travel distance to reach an exit would otherwise be excessive.

A.7.2.6.1 Examples of building elements that might be arranged as exit passageways include hallways, corridors, passages, tunnels, underfloor passageways, or overhead passageways.

A.7.2.6.4.1(1) Where an exit passageway serves occupants on the level of exit discharge as well as other floors, it should not be required that the occupant loads be added, thus increasing the width of the exit passageway. The situation is the same as that in which occupants from the level of exit discharge join occupants from upper floors for a few feet of horizontal travel through a stair enclosure.

A.7.2.8.7 Swinging stairs, although superior to fire escape ladders, are generally unsatisfactory, even for emergency use. Although such stairs are permitted by this *Code*, they should not be used where it is reasonably possible to terminate the fire escape stair at the finished ground level.

A.7.2.8.7.9 A latch is desirable for holding swinging stairs down after they have swung to the finished ground level.

A.7.2.11 Special consideration should be given prior to the application of such devices where children, the elderly, or physically disabled persons use such devices. These devices present obstacles in ascent and descent that differ from those for stairs and ladders.

A.7.2.12.2.3 A clear width of not less than 48 in. (1220 mm) is needed for a three-person carry of an occupied wheelchair up or down a stair. This procedure, as well as the more difficult two-person wheelchair carry or roll, requires training and experience. Safer alternative stair descent measures for transporting a person who normally requires a wheelchair, or otherwise cannot use stairs, include emergency stair travel devices designed, constructed, and operated in accordance with ANSI/RESNA ED-1, *Emergency Stair Travel Devices Used by Individuals with Disabilities*. In addition to having such devices available where needed, and having persons trained and experienced in their use, it is important to have people trained and experienced in wheelchair transfer techniques.

In view of the logistical difficulties, as well as the dangers inherent in carrying occupied wheelchairs or otherwise transferring and transporting their occupants on stairs, the preferred means of egress from an area of refuge consists of facilities normally employed for ingress and egress by people using wheelchairs. Foremost among these options are elevators meeting the fire fighters' emergency operations requirements of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*.

A.7.2.12.2.4 The use of elevators for egress, especially during an emergency such as a fire, is not an approach to be taken without considerable planning, ongoing effort, and a high degree of understanding by everyone involved with the evacuation of persons with mobility impairments. Due in part to the limited capacity of elevators, as well as to the conflicting demands for elevator use for fire-fighting activities, even elevators in accordance with 7.2.12.2.4 cannot be considered as satisfying any of the *Code*'s requirements for egress capacity, number of means of egress, or travel distance to an exit.

A.7.2.12.2.6 The instructions should include the following:

(1) Directions to find other means of egress
(2) Advice that persons able to use exit stairs do so as soon as possible, unless they are assisting others
(3) Information on planned availability of assistance in the use of stairs or supervised operation of elevators and how to summon such assistance
(4) Directions for use of the emergency communications system

To facilitate an adequate degree of understanding of the use of areas of refuge and of the associated assisted egress procedures, information should be provided to those using the facilities. The exact content of the information, its organization (e.g., as a set of instructions), and its format (e.g., either posted instructions in the area of refuge or information otherwise transmitted to facility users) should be determined on a case-by-case basis. The information should be tailored to the specific facility, its emergency action plan, the intended audience, and the intended presentation format. Suggested information content addressing two situations follows.

Refuge with Elevator Use. An area of refuge provided in the elevator lobby serves as a staging area for persons unable to use stairs and needing assistance for their evacuation during an emergency. The elevator(s) will be taken out of automatic service and operated by emergency service personnel. Persons unable to evacuate down the exit stairs without assistance and needing transportation by elevator should make certain the elevator lobby doors are closed while they wait in the elevator lobby for assistance. The two-way communication system should be used if there is a delay of more than several minutes in the arrival of an elevator that will provide transportation to the level of exit discharge. Alternatively, another refuge area, and assistance with evacuation, is available in the designated exit stair.

Refuge with Stair Use. An area of refuge within the designated exit stair serves as a staging area for persons needing assistance for their evacuation during an emergency. Persons unable to use the stairs unassisted, or who wish to move down the stairs at a slower pace, should wait on the stair landing. The two-way communication system should be used if assistance is needed.

A.7.2.12.3.1 Figure A.7.2.12.3.1 illustrates the application of the minimum space requirement to an area of refuge located within an exit stair enclosure. Note that each of the two required spaces is sufficient to allow the parking of a standard wheelchair. Preferably, such spaces should be provided adjacent to each other in a location where the presence of people taking temporary shelter in an area of refuge will be immediately apparent to rescue personnel and other evacuees.

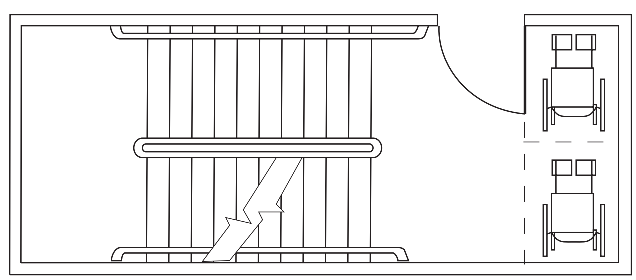

FIGURE A.7.2.12.3.1 Exit Stair Used as an Area of Refuge.

A.7.2.12.3.2 The method of meeting the tenability performance criteria required of an area of refuge of less than 1000 ft^2 (93 m^2) can involve controlling the exposing fire (e.g., via automatic sprinkler protection), installing smoke-resisting doors in the smoke-resisting barriers *(see* NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives),* providing smoke control to prevent or limit smoke migration through cracks or other leakage paths *(see* NFPA 92, *Standard* *for Smoke Control Systems),* or providing other means or a combination of these means.

Calculations, if used, need to be based on established engineering relationships and equations. Such calculational procedures are described in NFPA 92 and the *SFPE Handbook of Fire Protection Engineering*. Tenable conditions are those that maintain the temperature of any smoke in the area of refuge at less than 200°F (93°C) if the smoke is more than 60 in. (1525 mm) above the floor, and at less than 120°F (49°C) if the smoke descends below the 60 in. (1525 mm) level in the area of refuge. Also, if the smoke descends below the 60 in. (1525 mm) level, tenable conditions require not less than 16 percent oxygen and not more than 30,000 ppm/min exposure to carbon monoxide. The exposing conditions used in the calculations should be in accordance with the following:

(1) The exposing space is sprinkler protected, and the following conditions also exist:
    (a) The temperature of the exposing smoke is 200°F (93°C).
    (b) The smoke layer extends to the floor.
    (c) The oxygen content is 16 percent.
    (d) The carbon monoxide concentration is 2000 ppm (0.2 percent).
(2) The exposing space is a nonsprinklered corridor finished with Class A interior wall and ceiling finish, and the following conditions also exist:
    (a) The temperature of the exposing smoke is 600°F (316°C).
    (b) The smoke layer extends to a level 24 in. (610 mm) above the floor.
    (c) The oxygen content is 3 percent.
    (d) The carbon monoxide concentration is 50,000 ppm (5 percent).
(3) The exposing space is either not a corridor or, if a corridor, the corridor is not finished with a Class A interior wall and ceiling finish, and the following conditions also exist:
    (a) The temperature of the exposing smoke is 1500°F (815°C).
    (b) The smoke layer extends to a level 24 in. (610 mm) above the floor.
    (c) The oxygen content is 3 percent.
    (d) The carbon monoxide concentration is 50,000 ppm (5 percent).

A.7.2.12.3.4 Requirements for fire resistance ratings in excess of 1 hour, fire protection ratings in excess of 20 minutes, and prohibitions on duct penetrations appear in other *Code* sections. For example, if the barrier creating the area of refuge is also part of an exit stair enclosure that connects two or more stories, or is a horizontal exit, a minimum 2-hour fire resistance rating for the barrier and a minimum 1½-hour fire protection rating for opening protectives, such as doors, would be required for most occupancies.

For further information on door openings in smoke-resisting barriers, see NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*.

Generally, by providing one barrier that subdivides a floor area, two areas of refuge can be created. This subdivision method and the possibility of creating areas of refuge within compartmented elevator lobbies or on enlarged stair landings of exit stair enclosures make less onerous any requirement for a story to have more than one accessible means of egress.

A.7.2.13.1 It is the intent of 7.2.13.1 that elevators serving as a means of egress serve only independent towers or the tower portion of any integral structure. For elevators that are used as a component in the means of egress, the elevator lobbies, elevator shaft, and machine room need to be protected from the effects of fire.

A.7.2.13.6 One or more of the following approaches can be used to restrict exposure of elevator equipment to water:

(1) A combination of sealed elevator lobby doors, sloped floors, floor drains, and sealed elevator shaft walls is used.
(2) The elevator is mounted on the building exterior that normally operates in the elements, and seals are used on the elevator lobby doors.
(3) The elevator shaft is separated from the building at each floor by an exterior elevator lobby designed to prevent water entry into the elevator shaft.

Information gained from ongoing research concerning waterflow and elevators could lead to the development of water-resistive or water-protected elevator equipment specifically for fire applications. Such equipment should be used only with the building elements (e.g., sealed elevator lobby doors, sloped floors, floor drains) for which it is developed. Further information is available from the NIST publication, *Feasibility of Fire Evacuation by Elevators at FAA Control Towers*.

A.7.2.13.7 Cooling equipment dedicated to the elevator machine room can be used to minimize requirements for standby power.

A.7.2.13.8 Communication between elevator lobbies and a central control point can be by telephone or intercom. Auditory alarms should be designed so that they do not interfere with people talking on communications systems.

A.7.2.13.9 Smoke detection in the elevator lobby will result in a Phase I recall of the elevators. The elevators will then be automatically taken out of normal service and will be available to be operated by emergency service personnel.

A.7.3.1.2 The normal occupant load is not necessarily a suitable criterion, because the greatest hazard can occur when an unusually large crowd is present, which is a condition often difficult for authorities having jurisdiction to control by regulatory measures. The principle of this *Code* is to provide means of egress for the maximum probable number of occupants, rather than to attempt to limit occupants to a number commensurate with available means of egress. However, limits of occupancy are specified in certain special cases for other reasons.

Suggested occupant load factors for components of large airport terminal buildings are given in Table A.7.3.1.2. However, the authority having jurisdiction might elect to use different occupant load factors, provided that egress requirements are satisfied.

Table A.7.3.1.2 Airport Terminal Occupant Load Factors

Airport Terminal Area	ft^2 (gross)	m^2 (gross)
Concourse	100	9.3
Waiting areas	15	1.4
Baggage claim	20	1.9
Baggage handling	300	27.9

The figure used in determining the occupancy load for mall shopping centers of varying sizes was arrived at empirically by surveying over 270 mall shopping centers, by studying mercantile occupancy parking requirements, and by observing the number of occupants per vehicle during peak seasons.

These studies show that, with an increase in shopping center size, there is a decrease in the number of occupants per square foot of gross leasable area.

This phenomenon is explained when one considers that, above a certain shopping center gross leasable area [approximately 600,000 ft^2 (56,000 m^2)], there exists a multiplicity of the same types of stores. The purpose of duplicate types of stores is to increase the choices available to a customer for any given type of merchandise. Therefore, when shopping center size increases, the occupant load increases as well, but at a declining rate. In using Figure 7.3.1.2(a) or Figure 7.3.1.2(b), the occupant load factor is applied only to the gross leasable area that uses the mall as a means of egress.

The value for concentrated business use is intended to address business use spaces with a higher density of occupants than would normally be expected in a general business occupancy. Where furnishings and floor layouts are arranged to maximize the number of occupants in the space, the value for concentrated business use should be applied. Examples of concentrated business use areas are call centers, trading floors, and data processing centers.

A.7.3.3 In egress capacity calculations, standard rounding should be used.

A.7.3.3.2 The effective capacity of stairways has been shown by research to be proportional to the effective width of the stairway, which is the nominal width minus 12 in. (305 mm). This phenomenon, and the supporting research, were described in the chapter, “Movement of People,” in the first, second, and third editions of the *SFPE Handbook of Fire Protection Engineering* and was also addressed in Appendix D of the 1985 edition of NFPA 101, among several other publications. In 1988, this appendix was moved to form Chapter 2 of the 1988 edition of NFPA 101M, *Alternative Approaches to Life Safety*. (This document was later designated as NFPA 101A, *Guide on Alternative Approaches to Life Safety*, and this chapter remained in the document through the 1998 edition.) In essence, the effective width phenomenon recognizes that there is an edge or boundary effect at the sides of a circulation path. It has been best examined in relation to stairway width, where the edge effect was estimated to be 6 in. (150 mm) on each side, but a similar phenomenon occurs with other paths, such as corridors and doors, although quantitative estimates of their edge effect are not as well established as they have been for stairways, at least those stairways studied in Canada during the late 1960s through the 1970s in office building evacuation drills and in crowd movement in a variety of buildings with assembly occupancy.

More recent studies have not been performed to determine how the edge effect might be changing (or has changed) with demographic changes to larger, heavier occupants moving more slowly, and thus swaying laterally, to maintain balance when walking. The impact of such demographic changes, which are significant and influential for evacuation flow and speed of movement on stairs, for example, has the effect of increasing the time of evacuation in a way that affects all stair widths, but will be most pronounced for nominal widths less than 56 in. (1422 mm).

Without taking into account occupant demographic changes in the last few decades that affect evacuation performance, especially on stairs, the formula for enhanced capacity of stairways wider than 44 in. (1120 mm) assumes that any portion of the nominal width greater than 44 in. (1120 mm) is as effective proportionally as the effective width of a nominal 44 in. (1120 mm) stair, that is, 32 in. (810 mm). Thus, the denominator (0.218) in the equation is simply the effective width of 32 in. (810 mm) divided by the capacity of 147 persons that is credited, by the 0.3 in. (7.6 mm) capacity factor in Table 7.3.3.1, to the corresponding nominal width, 44 in. (1120 mm).

The resulting permitted stairway capacities, based on occupant load of single stories (in accordance with 7.3.1.4), for several stairway widths are shown in Table A.7.3.3.2.

Table A.7.3.3.2 Stairway Capacities

Permitted Capacity (no. of persons)	Nominal Width		Clear Width Between Handrails[a]		Effective Width	
	in.	mm	in.	mm	in.	mm
120[b]	36	915	28	710	24	610
147	44	1120	36	915	32	810
202	56	1420	48	1220	44	1120
257	68	1725	60	1525[c]	56	1420

[a]A reasonable handrail incursion of only 4 in. (100 mm), into the nominal width, is assumed on each side of the stair, although 7.3.3.2 permits a maximum incursion of 4½ in. (114 mm) on each side.

[b]Other *Code* sections limit the occupant load for such stairs more severely, (e.g., 50 persons in 7.2.2.2.1.2). Such lower limits are partly justified by the relatively small effective width of such stairs, which, if taken into account by Table 7.3.3.1, would result in a correspondingly low effective capacity of only 110 persons (24 divided by 0.218), or a more realistic capacity factor of 0.327, applicable to nominal width.

[c]A clear width of 60 in. (1525 mm) is the maximum permitted by the handrail reachability criteria of 7.2.2.4.1.2. Although some prior editions of the *Code* permitted wider portions of stairs [up to 88 in. (2240 mm), between handrails], such wider portions are less effective for reasonably safe crowd flow and generally should not be used for major crowd movement. To achieve the maximum possible, reasonably safe egress capacity for such stairs, retrofit of an intermediate — not necessarily central — handrail is recommended; for example, with an intermediate handrail located 36 in. (915 mm) from the closest side handrail. In this case, the effective capacity would be 358 persons for the formerly permitted, now retrofitted, stair. This is based on a retrofitted, effective width of about 78 in. (1980 mm) [subtracting 2 in. (51 mm) from each usable side of a handrail and assuming a 2 in. (51 mm) wide, retrofitted intermediate handrail].

A.7.3.4.1.1 The criteria of 7.3.4.1.1, as initially written, were intended to provide for minimum widths for small spaces such as individual offices. The intent is that these reductions in required width apply to spaces formed by furniture and movable walls, so that accommodations can easily be made for mobility-impaired individuals. One side of a path could be a fixed wall, provided that the other side is movable. This does not exempt the door widths or widths of fixed-wall corridors, regardless of the number of people or length. The allowance for reduction in width has been expanded to include all exit accesses serving not more than six people where the travel length along the reduced-width path does not exceed 50 ft (15 m), regardless of occupancy or use of the space.

Figure A.7.3.4.1.1(a) and Figure A.7.3.4.1.1(b) present selected anthropometric data for adults. The male and female figures depicted in the figures are average, 50th percentile, in size. Some dimensions apply to very large, 97.5 percentile, adults (noted as 97.5 P).

A.7.4 Section 7.4 requires a minimum number of means of egress, unless otherwise specified by an occupancy chapter in subsection ____.2.4, which addresses number of means of egress. Several occupancy chapters establish not only the minimum number of means of egress but also the minimum number of actual exits that must be provided on each floor. For example, for new educational occupancies, 14.2.4 requires access to two exits and further requires that both of the exits be provided on the floor. In contrast, for industrial occupancies, 40.2.4.1.1 requires access to two exits and further requires that at least one of the exits be located on the floor. Access to the other exit can involve traveling to another floor via an egress component such as an open stair, provided that such open stair is permitted by the occupancy chapter's provisions for the protection of vertical openings.

In most occupancy chapters, meeting the requirements for egress capacities and travel distances means the required minimum number of means of egress will automatically be met. However, in occupancies characterized by high occupant

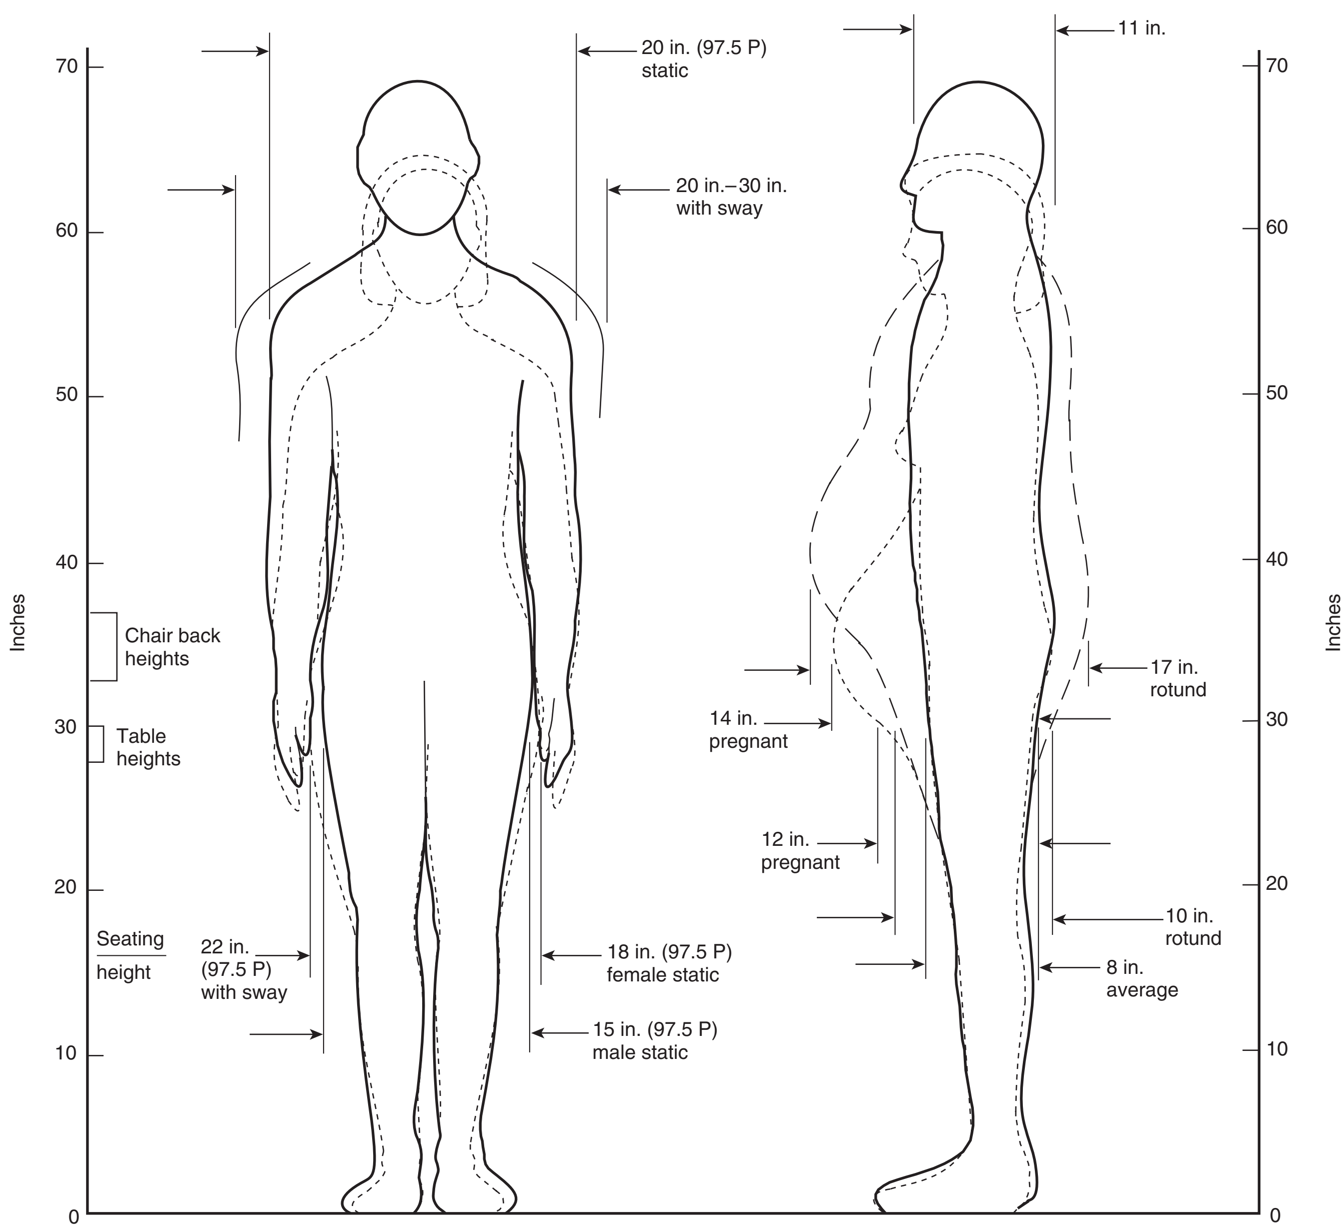

FIGURE A.7.3.4.1.1(a) Anthropometric Data (in in.) for Adults; Males and Females of Average, 50th Percentile, Size; Some Dimensions Apply to Very Large, 97.5 Percentile (97.5 P), Adults.

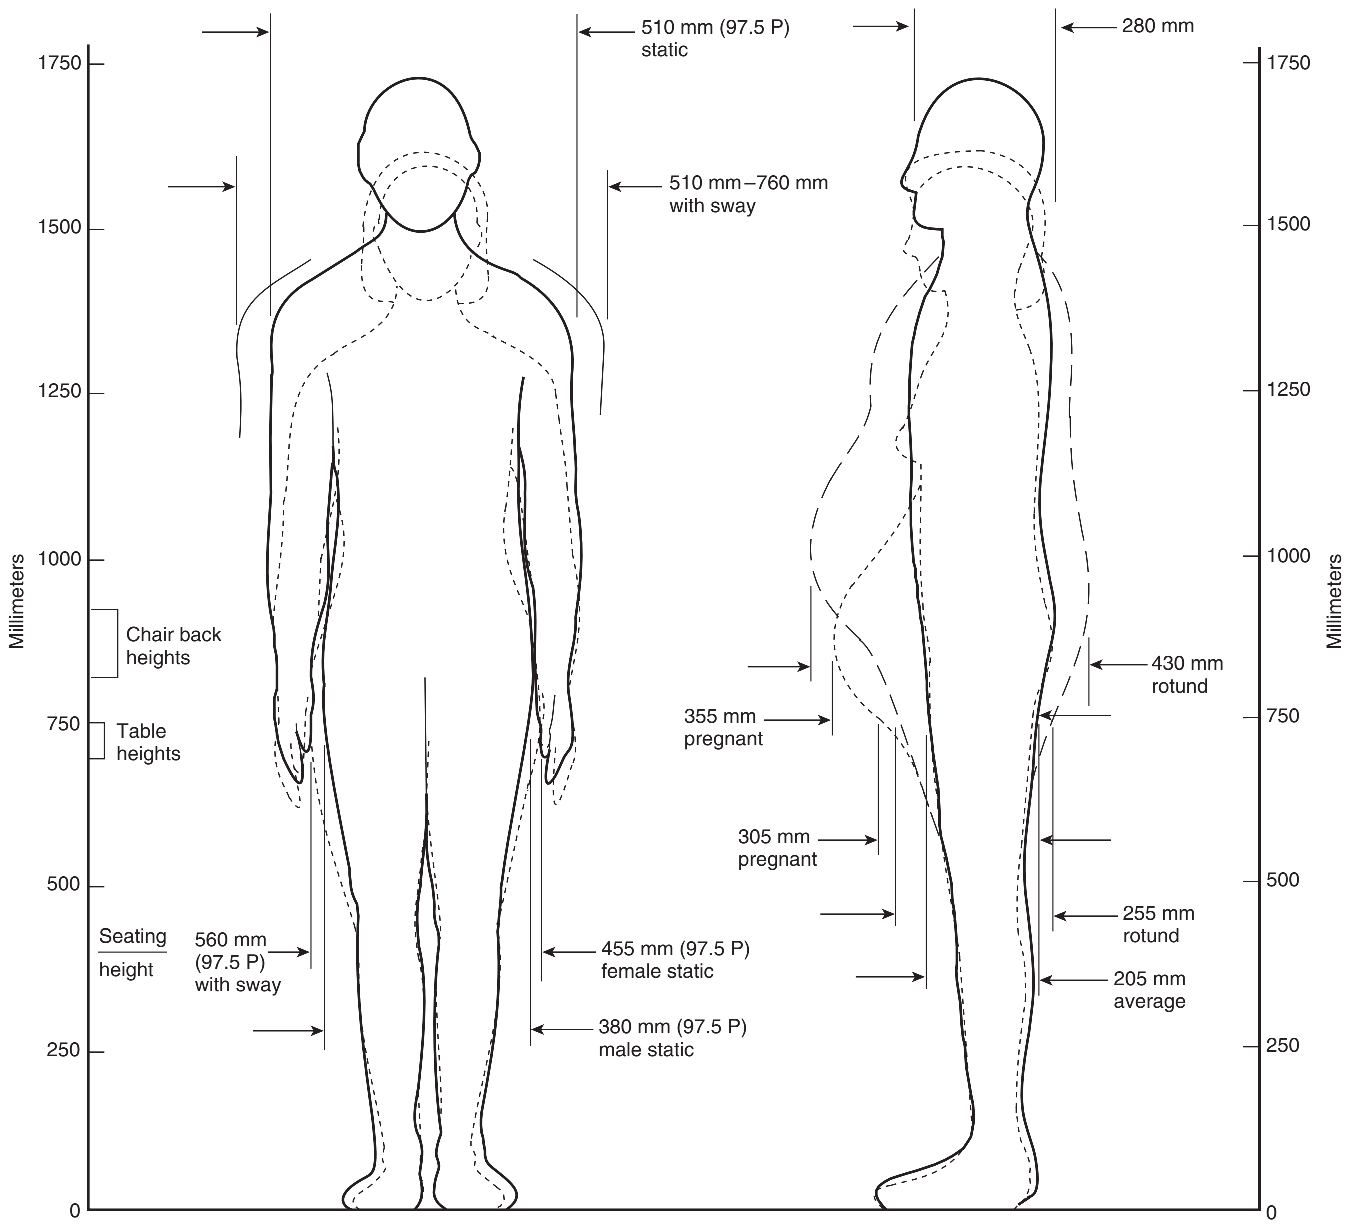

FIGURE A.7.3.4.1.1(b) Anthropometric Data (in mm) for Adults; Males and Females of Average, 50th Percentile, Size; Some Dimensions Apply to Very Large, 97.5 Percentile (97.5 P), Adults.

loads, such as assembly and mercantile occupancies, compliance with requirements for more than two exits per floor might require specific attention.

A.7.5.1.1.1 See A.7.5.1.5.

A.7.5.1.3.2 Figure A.7.5.1.3.2(a) through Figure A.7.5.1.3.2(e) illustrate the method of measurement intended by 7.5.1.3.2.

A.7.5.1.3.4 Figure A.7.5.1.3.4 illustrates the method of measuring exit separation distance along the line of travel within a minimum 1-hour fire resistance–rated corridor.

A.7.5.1.4.2 It is difficult in actual practice to construct scissor stairs so that products of combustion that have entered one stairway do not penetrate into the other. Their use as separate required exits is discouraged. The term *limited-combustible* is intentionally not included in 7.5.1.4.2. The user's attention is directed to the provisions for limited-combustible and noncombustible in 4.6.13 and 4.6.14, respectively.

A.7.5.1.5 The terms *dead end* and *common path of travel* are commonly used interchangeably. Although the concepts of each are similar in practice, they are two different concepts.

A common path of travel exists where a space is arranged so that occupants within that space are able to travel in only one direction to reach any of the exits or to reach the point at which the occupants have the choice of two paths of travel to

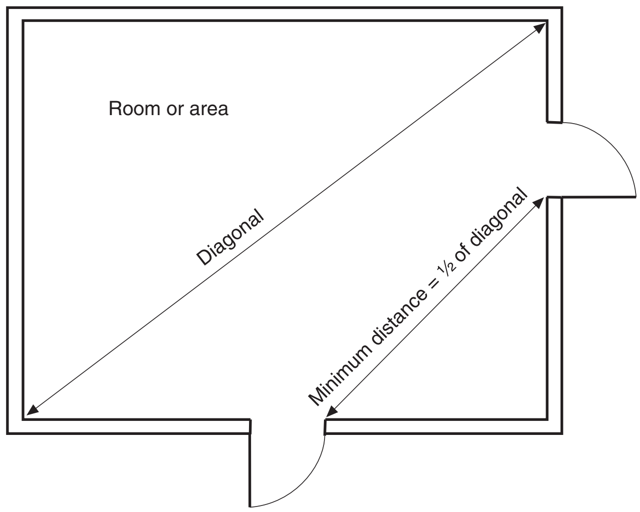

FIGURE A.7.5.1.3.2(a) **Diagonal Rule for Exit Remoteness.**

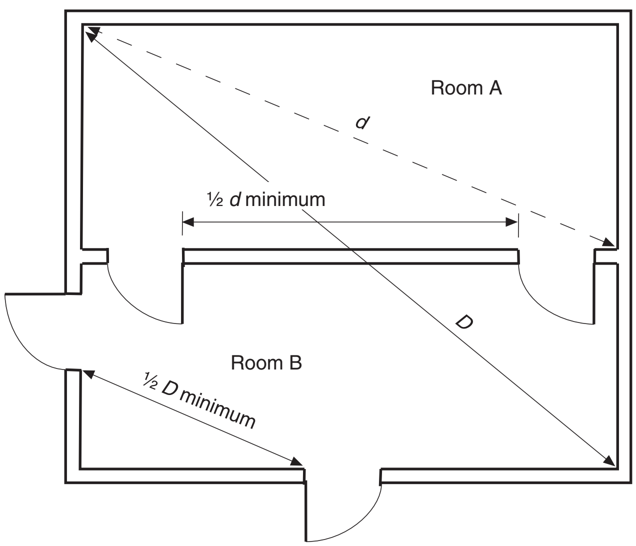

FIGURE A.7.5.1.3.2(b) Diagonal Rule for Exit and Exit Access Door Remoteness.

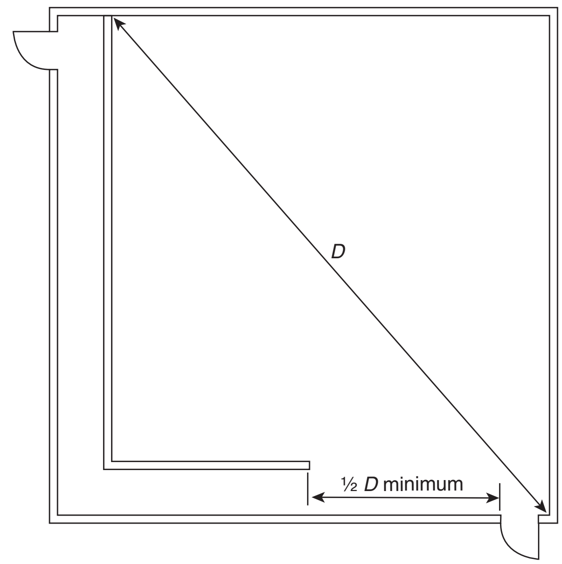

FIGURE A.7.5.1.3.2(c) Diagonal Rule for Exit and Access Remoteness.

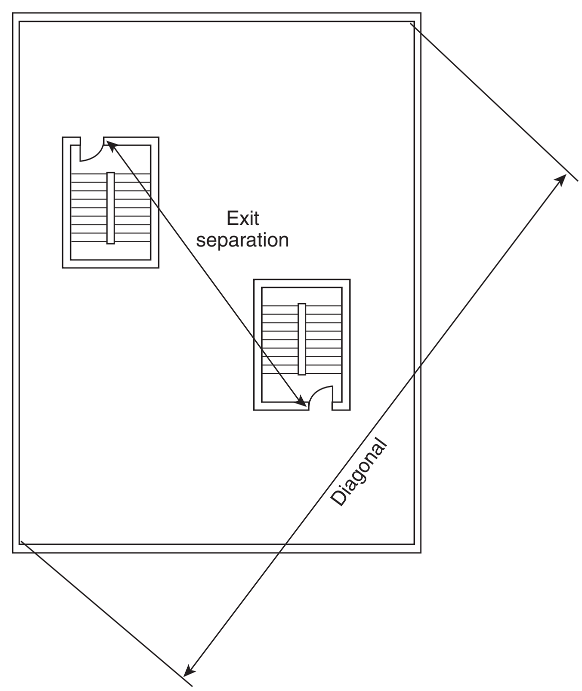

FIGURE A.7.5.1.3.2(d) Exit Separation and Diagonal Measurement of Area Served.

remote exits. Part (a) of Figure A.7.5.1.5 is an example of a common path of travel.

While a dead end is similar to a common path of travel, a dead end can exist where there is no path of travel from an occupied space but can also exist where an occupant enters a corridor thinking there is an exit at the end and, finding none, is forced to retrace his or her path to reach a choice of exits. Part (b) of Figure A.7.5.1.5 is an example of such a dead-end arrangement.

Combining the two concepts, part (c) of Figure A.7.5.1.5 is an example of a combined dead-end/common path of travel problem.

Common paths of travel and dead-end travel are measured using the same principles used to measure travel distance as described in Section 7.6. Starting in the room shown in part (d) of Figure A.7.5.1.5, measurement is made from the most remote point in the room, A, along the natural path of travel and through the doorway along the centerline of the corridor to point C, located at the centerline of the corridor, which then provides the choice of two different paths to remote exits; this is common path of travel. The space between point B and point C is a dead end. *(See 3.3.47 for the definition of common path of travel.)*

A.7.5.2.1 It is not the intent that an area with equipment such as a beverage brewpot, microwave oven, and a toaster be considered a kitchen.

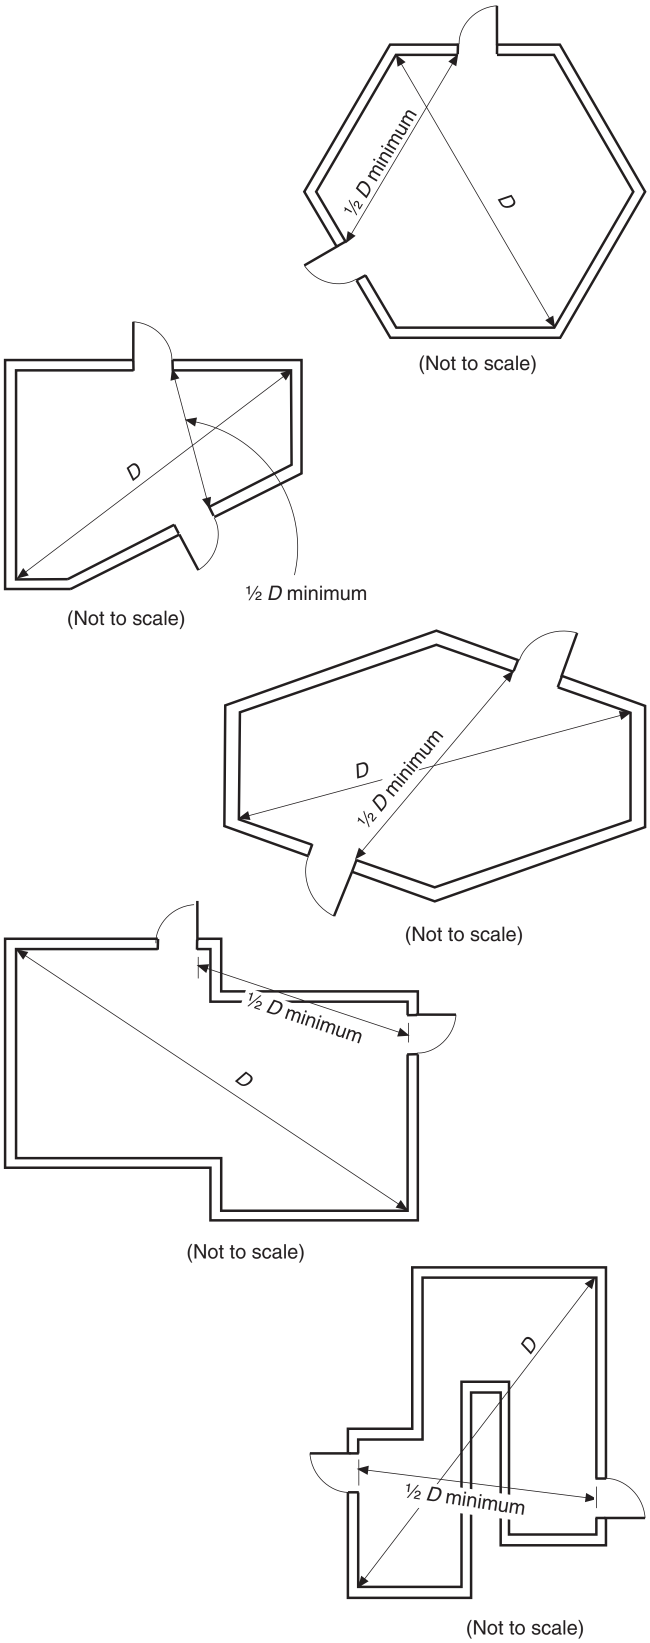

FIGURE A.7.5.1.3.2(e) Diagonal Measurement for Unusually Shaped Areas.

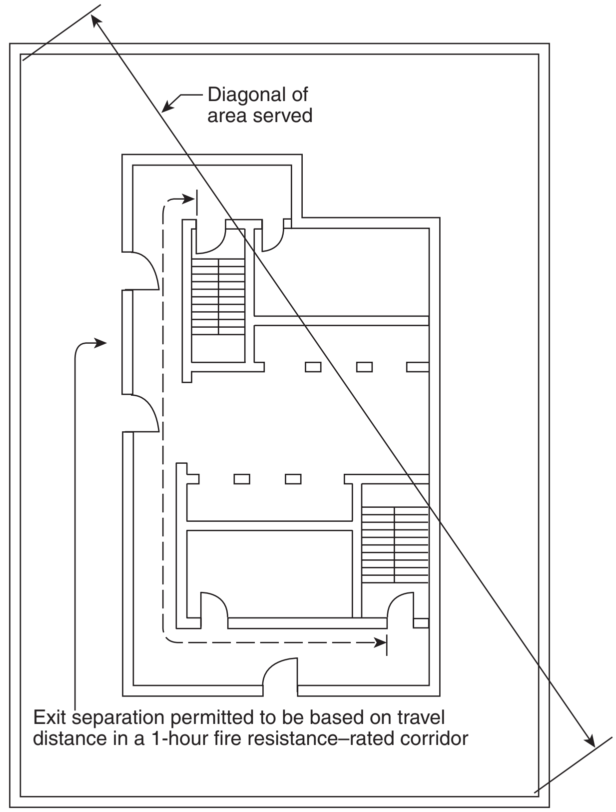

FIGURE A.7.5.1.3.4 Exit Separation Measured Along Corridor Path.

A.7.5.2.2 Doors that lead through wall paneling, and that harmonize in appearance with the rest of the wall to avoid detracting from some desired aesthetic or decorative effect, are not acceptable, because casual occupants might not be aware of such means of egress even though it is visible.

A.7.5.4.1 An accessible means of egress should comply with the accessible route requirements of ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities.*

A.7.6 Table A.7.6 is a compilation of the requirements of the individual occupancy chapters (Chapters 12 through 42) for permissible length of common path of travel, dead-end corridors, and travel distance to not less than one of the required exits.

A dead end exists where an occupant enters a corridor thinking there is an exit at the end and, finding none, is forced to retrace the path traveled to reach a choice of egress travel paths. Although relatively short dead ends are permitted by this *Code*, it is better practice to eliminate them wherever possible, as they increase the danger of persons being trapped in case of fire. Compliance with the dead-end limits does not necessarily mean that the requirements for remoteness of exits have been met. Such lack of compliance is particularly true in small buildings or buildings with short public hallways. Adequate remoteness can be obtained in such cases by further reducing the length of dead ends. *(See also A.7.5.1.5.)*

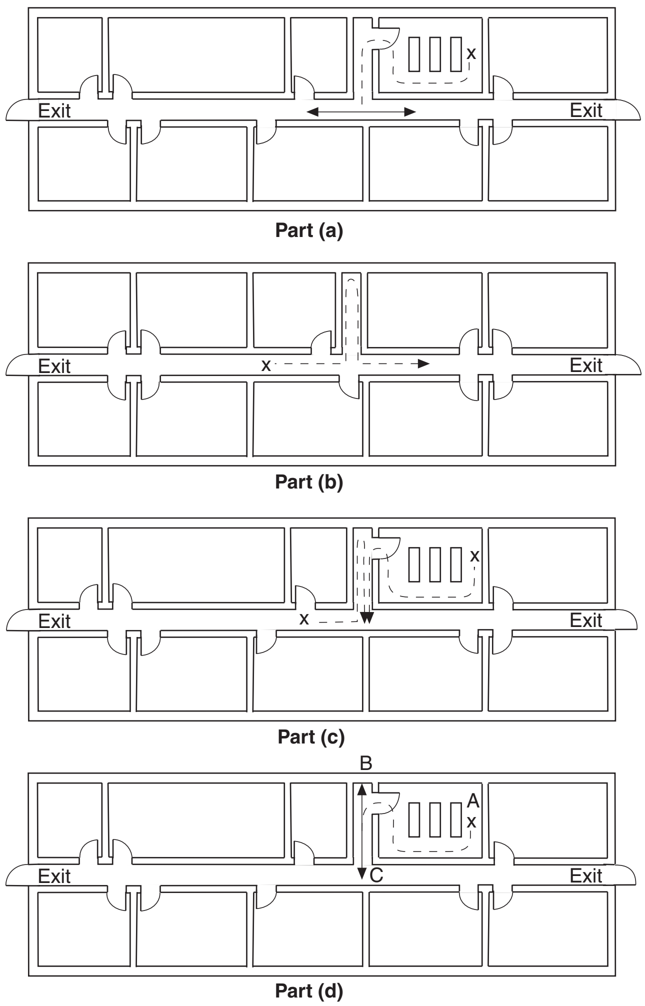

FIGURE A.7.5.1.5 Common Paths of Travel and Dead-End Corridors.

A.7.6.1 The natural exit access (path of travel) is influenced by the contents and occupancy of the building. Furniture, fixtures, machinery, or storage can serve to increase the length of travel. It is good practice in building design to recognize the influence of contents and occupancy by spacing exits for a completely open floor area at closer intervals than are required, thus reducing the hazard of excessive travel distances due to the introduction of furniture, fixtures, machinery, or storage and minimizing the possibility of violating the travel distance requirements of this *Code*.

A.7.6.3 Examples of locations where open stairways might exist include between mezzanines or balconies and the floor below.

A.7.7.1 An exit from the upper stories in which the direction of egress travel is generally downward should not be arranged so that it is necessary to change to travel in an upward direction at any point before discharging to the outside. A similar prohibition of reversal of the vertical component of travel should be applied to exits from stories below the floor of exit discharge. However, an exception is permitted in the case of stairs used in connection with overhead or underfloor exit passageways that serve the street floor only.

It is important that ample roadways be available from buildings in which there are large numbers of occupants so that exits will not be blocked by persons already outside. Two or more avenues of departure should be available for all but very small places. Location of a larger theater — for example, on a narrow dead-end street — might be prohibited by the authority having jurisdiction under this rule, unless some alternate way of travel to another street is available.

Exterior walking surfaces within the exit discharge are not required to be paved and often are provided by grass or similar surfaces. Where discharging exits into yards, across lawns, or onto similar surfaces, in addition to providing the required width to allow all occupants safe access to a public way, such access also is required to meet the following:

(1) Provisions of 7.1.7 with respect to changes in elevation
(2) Provisions of 7.2.2 for stairs, as applicable
(3) Provisions of 7.2.5 for ramps, as applicable
(4) Provisions of 7.1.10 with respect to maintaining the means of egress free of obstructions that would prevent its use, such as snow and the need for its removal in some climates

A.7.7.3.3 Examples include partitions and gates. The design should not obstruct the normal movement of occupants to the exit discharge. Signs, graphics, or pictograms, including tactile types, might be permitted for existing exit enclosures where partitions or gates would obstruct the normal movement of occupants to the exit discharge.

A.7.8.1.1 Illumination provided outside the building should be to either a public way or a distance away from the building that is considered safe, whichever is closest to the building being evacuated.

A.7.8.1.2.2 Photoluminescent materials and battery-powered luminaires require some period of time to restore themselves to full operational capacity after being de-energized.

Photoluminescent products rely on nearby luminaires to maintain their full capacity. When those luminaires are de-energized, the photoluminescent product will gradually deplete its capacity. Listed photoluminescent exit signs and path markers are restored to full rated capacity within one hour, and there is no known limit to the number of times they can be discharged and recharged, nor any known degradation of overall capacity or lifetime as a result of discharge/charge cycles.

De-energizing the normal (utility) power source will automatically begin the battery discharge cycle of emergency luminaires, unit equipment, and exit signs provided with battery backup. Once drained, these batteries will typically require between 24 and 72 hours, depending on the battery technology and charging circuitry design, to regain full capacity. Frequent discharge/charge cycles can reduce overall battery lifetime and, depending on battery technology, might also prematurely reduce overall battery capacity.

A.7.8.1.2.3 A consideration for the approval of automatic, motion sensor–type lighting switches, controls, timers, or controllers is whether the equipment is listed as a fail-safe device for use in the means of egress.

A.7.8.1.3(4) Some processes, such as manufacturing or handling of photosensitive materials, cannot be performed in areas provided with the minimum specified lighting levels. The use of spaces with lighting levels below 1 ft-candle (10.8 lux) might necessitate additional safety measures, such as written emergency action plans, training of new employees in emergency evacuation procedures, and periodic fire drills.

[a]For common path serving >50 persons, 20 ft (6.1 m); for common path serving ≤50 persons, 75 ft (23 m).

[b]Dead-end corridors of 20 ft (6.1 m) permitted; dead-end aisles of 20 ft (6.1 m) permitted.

[c]See Chapters 12 and 13 for special considerations for smoke-protected assembly seating in arenas and stadia.

[d]This dimension is for the total travel distance, assuming incremental portions have fully utilized their permitted maximums. For travel distance within the room, and from the room exit access door to the exit, see the appropriate occupancy chapter.

[e]See 19.2.5.2.

[f]See business occupancies, Chapters 38 and 39.

[g]See Chapter 23 for special considerations for existing common paths.

[h]This dimension is from the room/corridor or suite/corridor exit access door to the exit; thus, it applies to corridor common path.

[i]See the appropriate occupancy chapter for requirements for second exit access based on room area.

[j]See the appropriate occupancy chapter for special travel distance considerations for exterior ways of exit access.

[k]See 36.4.4 and 37.4.4 for special travel distance considerations in covered malls considered to be pedestrian ways.

[l]See Chapters 38 and 39 for special common path considerations for single-tenant spaces.

[m]See Chapters 40 and 42 for special requirements on spacing of doors in aircraft hangars.

[n]See Chapter 40 for industrial occupancy special travel distance considerations.

[o]See Chapters 40 and 42 for special requirements if high hazard conditions exist.

[p]See 42.8.2.6.2 for special travel distance considerations in open parking structures.

A.7.8.1.4 Failure of a lighting unit is deemed to have occurred when the light output drops below 70 percent of its original level.

A.7.9.1.1 Emergency lighting outside the building should provide illumination to either a public way or a distance away from the building that is considered safe, whichever is closest to the building being evacuated.

A.7.9.2.3 Where emergency lighting is provided by automatic transfer between normal power service and an emergency generator, it is the intent to prohibit the installation, for any reason, of a single switch that can interrupt both energy sources.

A.7.9.3.1.1(2) Technical justification for extending test intervals past 30 days should be based on recorded event history (data) and should include evaluation of the following criteria:

(1) Number of egress lighting units
(2) Number of 30-second tests for analysis
(3) Re-evaluation period (confirm or adjust intervals)
(4) Number of fixtures found obstructed
(5) Number of fixtures found misaligned
(6) Fixtures found to be missing
(7) Fixtures found damaged
(8) Battery design
(9) Type of light source
(10) Fixture design (manufacturer)
(11) Number of light fixtures per exit path
(12) Existence of fire, smoke, and thermal barriers
(13) Evacuation capability
(14) Maximum egress time
(15) Hours of occupancy
(16) Number of recorded bulb failures
(17) Number of recorded fixture failures
(18) Single fixture reliability
(19) Repairs — mean time to repair
(20) Lighted egress path probability of success or failure — monthly upper tolerance limit
(21) Lighted egress path probability of success or failure — quarterly upper tolerance limit (estimated)

A.7.10.1.2.1 Where a main entrance also serves as an exit, it will usually be sufficiently obvious to occupants so that no exit sign is needed.

The character of the occupancy has a practical effect on the need for signs. In any assembly occupancy, hotel, department store, or other building subject to transient occupancy, the need for signs will be greater than in a building subject to permanent or semipermanent occupancy by the same people, such as an apartment house where the residents are presumed to be familiar with exit facilities by reason of regular use thereof. Even in a permanent residence–type building, however, there is a need for signs to identify exit facilities, such as outside stairs that are not subject to regular use during the normal occupancy of the building.

The requirement for the locations of exit signs visible from any direction of exit access is illustrated in Figure A.7.10.1.2.1.

A.7.10.1.2.2 The direction of travel to the exit discharge within a stair enclosure with horizontal components in excess of the typical landings might need additional signage to be readily visible or obvious. Exit signs should be installed above doors through which the egress path leads. Directional exit signs should be installed where the horizontal egress path changes directions. The stairway marking signs required by 7.2.2.5.4, provided within the stair enclosure at each floor landing, indicate the vertical direction to exit discharge.

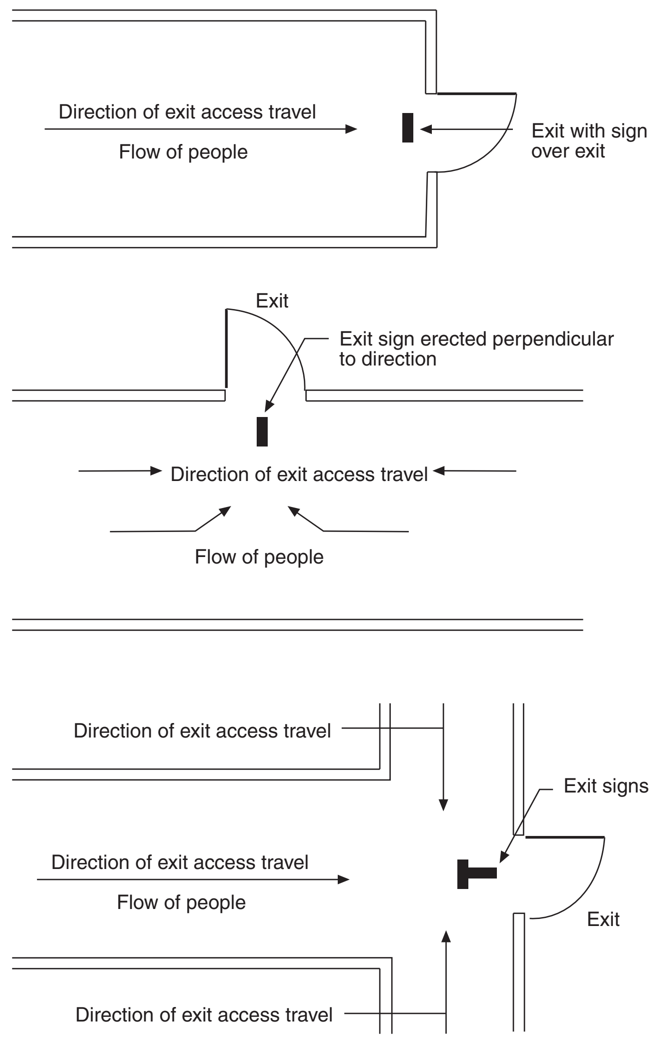

FIGURE A.7.10.1.2.1 Location of Exit Signs.

A.7.10.1.5.2 For externally illuminated signs in accordance with 7.10.6 and internally illuminated signs listed without a marked viewing distance, the rated viewing distance should be considered to be 100 ft (30 m). Where placing signs at their rated viewing distance requires them to be placed above the line of sight, consideration should be given to proportionally increasing the size of the exit legend to compensate for the additional straight-line distance between the viewer and the sign.

A.7.10.1.6 See A.7.10.3.

A.7.10.1.7 See 3.3.146.2 for the definition of the term *internally illuminated.*

A.7.10.1.8 In stores, for example, an otherwise adequate exit sign could be rendered inconspicuous by a high-intensity illuminated advertising sign located in the immediate vicinity.

Red is the traditional color for exit signs and is required by law in many places. However, at an early stage in the development of the *Code*, a provision made green the color for exit signs, following the concept of traffic lights in which green indicates safety and red is the signal to stop. During the period when green signs were specified by the *Code*, many such signs were installed, but the traditional red signs also remained. In 1949, the Fire Marshals Association of North America voted to request that red be restored as the required exit sign color, because it was found that the provision for green involved difficulties in law enactment that were out of proportion to the importance of safety. Accordingly, the 10th edition of the *Code* specified red where not otherwise required by law. The present text avoids any specific requirement for color, based on the assumption that either red or green will be used in most cases and that there are some situations in which a color other than red or green could actually provide better visibility.

A.7.10.3 Where graphics are used, the symbols provided in NFPA 170, *Standard for Fire Safety and Emergency Symbols*, should be used. Such signs need to provide equal visibility and illumination and are to comply with the other requirements of Section 7.10.

A.7.10.3.2 Pictograms are permitted to be used in lieu of, or in addition to, signs with text.

A.7.10.4 It is not the intent of this paragraph to require emergency lighting but only to have the sign illuminated by emergency lighting if emergency lighting is required and provided.

It is not the intent to require that the entire stroke width and entire stroke height of all letters comprising the word EXIT be visible per the requirements of 7.10.6.3 under normal or emergency lighting operation, provided that the sign is visible and legible at a 100 ft (30 m) distance under all room illumination conditions.

A.7.10.5.1 See A.7.8.1.3(4).

A.7.10.5.2 It is the intent to prohibit the use of a freely accessible light switch to control the illumination of either an internally or externally illuminated exit sign.

A.7.10.5.2.2 The flashing repetition rate should be approximately one cycle per second, and the duration of the off-time should not exceed ¼ second per cycle. During on-time, the illumination levels need to be provided in accordance with 7.10.6.3. Flashing signs, when activated with the fire alarm system, might be of assistance.

A.7.10.6.1 Experience has shown that the word EXIT, or other appropriate wording, is plainly legible at 100 ft (30 m) if the letters are as large as specified in 7.10.6.1.

A.7.10.6.2 Figure A.7.10.6.2 shows examples of acceptable locations of directional indicators with regard to left and right orientation. Directional indicators are permitted to be placed under the horizontal stroke of the letter T, provided that spacing of not less than ⅜ in. (10 mm) is maintained from the horizontal and vertical strokes of the letter T.

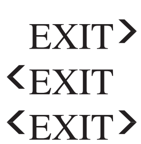

FIGURE A.7.10.6.2 Directional Indicators.

A.7.10.6.3 Colors providing a good contrast are red or green letters on matte white background. Glossy background and glossy letter colors should be avoided.

The average luminance of the letters and background is measured in footlamberts or candela per square meter. The contrast ratio is computed from these measurements by the following formula:

$$\text{Contrast} = \frac{L_g - L_e}{L_g} \qquad \textbf{[A.7.10.6.3]}$$

Where L_g is the greater luminance and L_e is the lesser luminance, either the variable L_g or L_e is permitted to represent the letters, and the remaining variable will represent the background. The average luminance of the letters and background can be computed by measuring the luminance at the positions indicated in Figure A.7.10.6.3 by numbered circles.

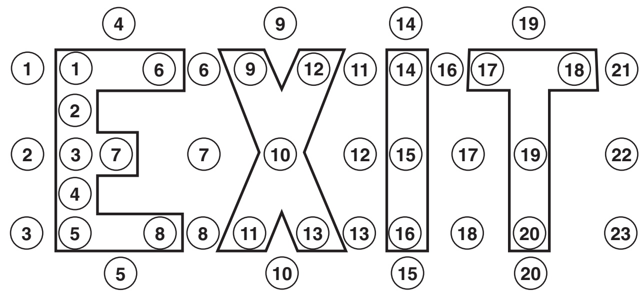

FIGURE A.7.10.6.3 Measurement of Exit Sign Luminance.

A.7.10.7.2 Photoluminescent signs need a specific minimum level of light on the face of the sign to ensure that the sign is charged for emergency operation and legibility in both the normal and emergency modes. Additionally, the type of light source (e.g., incandescent, fluorescent, halogen, metal halide) is important. Each light source produces different types of visible and invisible light (e.g., UV) that might affect the ability of some photoluminescent signs to charge and might also affect the amount of light output available during emergency mode. This type of sign would not be suitable where the illumination levels are permitted to decline. The charging light source should not be connected to automatic timers, because continuous illumination of the sign is needed; otherwise, the sign illumination would not be available, because it would be discharged.

A.7.10.8.1.1 Special signs require sufficient illumination in order for them to be readable at close proximity. They are not expected to be of a size or illumination level necessary to be readable from a distance, as is the case for an exit sign.

A.7.10.8.3 The likelihood of occupants mistaking passageways or stairways that lead to dead-end spaces for exit doors and becoming trapped governs the need for exit signs. Thus, such areas should be marked with a sign that reads as follows:

NO EXIT

Supplementary identification indicating the character of the area, such as TO BASEMENT, STOREROOM, LINEN CLOSET, or the like, is permitted to be provided.

A.7.10.8.4(1) These signs are to be used in place of signs that indicate that elevators are not to be used during fires. Examples of these signs include the following:

In the Event of Fire, This Elevator Will Be Used

by the Fire Department for Evacuation of People.

PROTECTED ELEVATOR —

USABLE IN EMERGENCIES

A.7.10.8.4(2) The wording of these signs should reflect human behavior in fires and the control specifics of the elevator system. Subparagraph 7.10.8.4 addresses signs, but provisions for notification of the vision impaired need to be considered. For information about human behavior with respect to elevator evacuation, see Groner and Levin, "Human Factor Considerations in the Potential for Using Elevators in Building Emergency Evacuation Plans"; Levin and Groner, "Human Behavior Aspects of Staging Areas for Fire Safety in GSA Buildings"; and Levin and Groner, "Human Factor Considerations for the Potential Use of Elevators for Fire Evacuation of FAA Air Traffic Control Towers." Some examples of messages on signs that could be displayed are shown in Table A.7.10.8.4(2).

Table A.7.10.8.4(2) Elevator Status Messages

Elevator Status	Message
Normal use	Elevator in Service
Elevators recalled and waiting for fire service	Please Wait for Fire Department or Use Stairs
Elevator out of service	Elevator Out of Service

A.7.10.8.5 Egress paths with multiple turns can often be confusing with respect to which exit route will lead to the closest exit door. Floor evacuation diagrams can eliminate the guesswork by giving the occupant a point of reference by the YOU ARE HERE symbol. The entire floor plan should be shown with the primary and secondary exit routes, exit stairs, and elevators clearly identified. For further information, see ASTM E 2238, *Standard Guide for Evacuation Route Diagrams*.

A.7.11.1 Seventy-five feet (23 m) can be traversed in approximately 10 seconds to 15 seconds, even when allowing for a momentary delay to decide which way to go, during which it can be assumed that the average individual can hold his or her breath.

A.7.13.1 29 CFR 1910.146 of the OSHA regulations describes the aspects of normally unoccupied areas. For example, hazardous atmosphere criteria are presented, and asphyxiation risk due to an entrance becoming engulfed are addressed. The areas described by 29 CFR 1910.146, "Permitted Required Confined Spaces," would be considered hazardous if located within a building or structure regulated by NFPA 101.

A.7.13.2.1 Egress from normally unoccupied building service equipment support areas not exceeding 45,000 ft^2 (4180 m^2) is permitted to be by access panels or other hardware not complying with the door requirements of 7.2.1.

A.7.14.1.1 The Phase I emergency recall operation mandated by the fire fighters' emergency operation provisions of ASME A17.1/CSA B 44, *Safety Code for Elevators and Escalators*, recalls elevators upon detection of smoke by smoke detectors installed in the following locations:

(1) At each floor served by the elevator in the lobby (landing) adjacent to the hoistway doors
(2) In the associated elevator machine/control room or machinery/control space
(3) In the elevator hoistway where sprinklers are located in the hoistway

Where smoke from a fire remote from the elevator lobby (landing), elevator machine/control room or machinery/control space, and elevator hoistway can be kept from reaching the elevator lobby (landing), elevator machine/control room or machinery/control space, and elevator hoistway, the associated elevators can continue to operate in a fire emergency. The provisions of Section 7.14 address the features that need to be provided to make such elevator operation safe for evacuation.

A.7.14.1.3 The occupant evacuation operation requirements of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators,* address the elevator-related features for occupant evacuation elevators — features for which an elevator code has jurisdiction. The requirements were written assuming that necessary and complementary provisions that are not within the purview of an elevator code would be addressed in building, life safety, and fire codes. ASME A17.1/CSA B44 Annex T, titled "Building Features for Elevator Occupant Evacuation Operation (OEO)," lists the building construction features assumed to be present for coordinated use with its provisions for OEO.

A.7.14.3.1 Building occupants have traditionally been taught not to use elevators in fire or similar emergencies. The emergency action plan should include more than notification that the elevators can be used for emergency evacuation. The plan should include training to make occupants aware that the elevators will be available only for the period of time prior to elevator recall via smoke detection in the elevator lobby, elevator machine/control room or machinery/control space, or elevator hoistway. Occupants should be prepared to use the exit stairs, which are required to be directly accessible from the elevator lobby by 7.14.9.3, where the elevator has been called out of service.

A.7.14.4.2 The emergency voice/alarm communication system with the ability to provide voice directions on a selective basis to any building floor might be used to instruct occupants of the fire floor who are able to use stairs to relocate to a floor level below. The selective voice notification feature might be used to provide occupants of a given elevator lobby with a status report or supplemental instructions.

A.7.14.4.3 An audible notification appliance will need to be positioned in the elevator lobby in order to meet the requirement of 7.14.3.4. The continued use of the occupant evacuation elevator system is predicated on elevator lobby doors that are closed to keep smoke from reaching the elevator lobby smoke detector that is arranged to initiate the Phase I emergency recall operation.

A.7.14.5.2 The presence of sprinklers in the elevator machine/control room or machinery/control space would necessitate the installation of a shunt trip for automatically disconnecting the main line power for compliance with ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators,* as it is unsafe to operate elevators while sprinkler water is being discharged in the elevator machine/control room or machinery/control space. The presence of a shunt trip conflicts with the needs of the occupant evacuation elevator, as it disconnects the power without ensuring that the elevator is first returned to a safe floor so as to prevent trapping occupants.

A.7.14.5.3 NFPA 13, *Standard for the Installation of Sprinkler Systems*, permits sprinklers to be omitted from the top of the elevator hoistway where the hoistway for passenger elevators is noncombustible and the car enclosure materials meet the requirements of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*. The provision of 7.14.5.3 restricts occupant evacuation elevators to passenger elevators that are in noncombustible hoistways and for which the car enclosure materials meet the requirements of ASME A17.1/CSA B 44.

A.7.14.6.2 Elevator shunt breakers are intended to disconnect the electric power to an elevator prior to sprinkler system waterflow impairing the functioning of the elevator. The provision of 7.14.5.2 prohibits the installation of sprinklers in the elevator machine/control room or machinery/control space and at the top of the elevator hoistway, obviating the need for shunt breakers. The provision of 7.14.6.2 is not actually an exemption to the provisions of ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, as ASME A17.1/CSA B44 requires the automatic main line power disconnect (shunt trip) only where sprinklers are located in the elevator machine/control room or machinery/control space or in the hoistway where it could cause unsafe elevator operation. The provision of 7.14.5.2 prohibits sprinklers in the elevator machine/control room and machinery/control space. The provision of 7.14.5.3 prohibits sprinklers at the top of the hoistway and at other points in the hoistway more than 24 in. (610 mm) above the pit floor in recognition of the limitations on combustibility established by 7.14.6.3.

A.7.14.7.1 The minimum 2-hour fire resistance–rated separation is based on the omission of sprinklers from the elevator machine room in accordance with 7.14.5.3.

A.7.14.7.2 The requirement of 7.14.7.2 is consistent with that in ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*, which permits only machinery and equipment used in conjunction with the function or use of the elevator to be in the elevator machine/control room or machinery/control space. An inspection program should be implemented to ensure that the elevator machine/control room or machinery/control space is kept free of storage.

A.7.14.8.3 Wiring or cables that provide control signals are exempt from the protection requirements of 7.14.8.2, provided that such wiring or cables, where exposed to fire, will not disable Phase II emergency in-car operation once such emergency operation has been activated.

A.7.14.9.2 Elevator lobbies provide a safe place for building occupants to await the elevators and extend the time available for such use by providing a barrier to smoke and heat that might threaten the elevator car or hoistway. Smoke detectors within the elevator lobbies are arranged to initiate a Phase I emergency recall operation if the lobby is breached by smoke.

A.7.14.9.6 The performance-based language of 7.14.9.6 permits alternate design options to prevent water from an operating sprinkler system from infiltrating the hoistway enclosure. For example, such approved means might include drains and sloping the floor. The objective of the water protection requirement is to limit water discharged from sprinklers operating on the floor of fire origin from entering the hoistway, as it might by flowing into the lobby and under the landing doors, interfering with safety controls normally located on the front of the elevator car. A small flow of water (of the order of the flow from a single sprinkler) should be able to be diverted by the landing doorway nose plate to the sides of the opening, where it can do little harm. The requirement is intended to protect from water from sprinklers outside the elevator lobby, since the activation of sprinklers in the lobby would be expected to be preceded by activation of the lobby smoke detector that recalls the elevators.

Water protection can be achieved in any of several ways. Mitigation features that should be effective in keeping the waterflow from a sprinkler out of the hoistway include the following:

(1) Raised lip in accordance with 7.1.6.2 and a floor drain
(2) Sloped floor and a floor drain
(3) Sealed sill plates and baseboards on both sides of the lobby partitions and along the perimeter of the hoistway shaft

A.8.2.1.2 Table A.8.2.1.2 is from *NFPA 5000*, *Building Construction and Safety Code*, and is reproduced in this annex for the convenience of users of this *Code*.

It is not the intent to require exterior walls to be protected against exterior fire exposure except where specifically required by NFPA 220 or *NFPA 5000*. Other building codes might also require protection from the exterior in some circumstances. The presence of fire sprinklers or an occupiable exterior space, such as a porch or balcony, does not require protection against exterior fire exposure unless specifically required elsewhere.

A.8.2.3.1 ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, and ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*, are considered nationally recognized methods of determining fire resistance and have been found to yield equivalent test results.

A.8.2.4.2 The intent of this provision is to allow the provisions of either ASCE/SFPE 29, *Standard Calculation Methods for Structural Fire Protection*, or ACI 216.1/TMS 0216.1 *Code Requirements for Determining Fire Resistance of Concrete and Masonry Construction Assemblies,* for the calculation for fire resistance of concrete or masonry elements or assemblies.

A.8.3.1.1(4) Walls in good condition with lath and plaster, or gypsum board of not less than ½ in. (13 mm) on each side, can be considered as providing a minimum ½-hour fire resistance rating. Additional information on archaic material assemblies can be found in Annex O of NFPA 914, *Code for Fire Protection of Historic Structures*.

A.8.3.1.2 To ensure that a fire barrier is continuous, it is necessary to seal completely all openings where the fire barrier abuts other fire barriers, the exterior walls, the floor below, and the floor or ceiling above. In 8.3.1.2(2), the fire resistance rating of the bottom of the interstitial space is provided by that membrane alone. Ceilings of rated floor/ceiling and roof/ceiling assemblies do not necessarily provide the required fire resistance.

A.8.3.2.1.1 Fire resistance–rated glazing complying with 8.3.2, where not installed in a door, is considered a wall, not an opening protective.

A.8.3.3.2 Some door assemblies have been tested to meet the conditions of acceptance of ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and Materials*. Where such assemblies are used, the provisions of 8.3.2 should be applied instead of those of 8.3.3.2.

A.8.3.3.2.3 In existing installations, it is important to be able to determine the fire protection rating of the fire door. However, steel door frames that are well set in the wall might be judged as acceptable even if the frame label is not legible.

A.8.3.3.6 Some window assemblies have been tested to meet the conditions of acceptance of ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*, or ANSI/UL 263, *Standard for Fire Tests of Building Construction and*

Table A.8.2.1.2 Fire Resistance Ratings for Type I Through Type V Construction (hours)

	Type I		Type II			Type III		Type IV	Type V	
Construction Element	**442**	**332**	**222**	**111**	**000**	**211**	**200**	**2HH**	**111**	**000**
Exterior Bearing Walls [a]										
Supporting more than one floor, columns, or other bearing walls	4	3	2	1	0[b]	2	2	2	1	0[b]
Supporting one floor only	4	3	2	1	0[b]	2	2	2	1	0[b]
Supporting a roof only	4	3	1	1	0[b]	2	2	2	1	0[b]
Interior Bearing Walls										
Supporting more than one floor, columns, or other bearing walls	4	3	2	1	0	1	0	2	1	0
Supporting one floor only	3	2	2	1	0	1	0	1	1	0
Supporting roofs only	3	2	1	1	0	1	0	1	1	0
Columns										
Supporting more than one floor, columns, or other bearing walls	4	3	2	1	0	1	0	H	1	0
Supporting one floor only	3	2	2	1	0	1	0	H	1	0
Supporting roofs only	3	2	1	1	0	1	0	H	1	0
Beams, Girders, Trusses, and Arches										
Supporting more than one floor, columns, or other bearing walls	4	3	2	1	0	1	0	H	1	0
Supporting one floor only	2	2	2	1	0	1	0	H	1	0

[***5000:*** Table 7.2.1.1]

Materials. Where such assemblies are used, the provisions of 8.3.2 should be applied instead of those of 8.3.3.6.

A.8.3.4.2 Longer ratings might be required where opening protectives are provided for property protection as well as life safety. NFPA 80, *Standard for Fire Doors and Other Opening Protectives,* should be consulted for standard practice in the selection and installation of fire door assemblies and fire window assemblies.

Table 8.3.4.2. A vision panel in a fire door is not a fire window, and, thus, it is not the intent of the "NP" notations in the "Fire Window Assemblies" column of Table 8.3.4.2 to prohibit vision panels in fire doors.

A.8.3.5.1 Firestop materials become systems when installed to the listed firestop system design from an accredited testing laboratory. Installation of firestop materials to the listed system should meet all limitations of the system.

There are management system–based contractor approval or qualification programs offered by third-party, independent companies that quantifiably qualify a company to install firestop materials that become systems after proper installation. In each program, there is an industry firestop exam that gives the company a basis to appoint a "Designated Responsible Individual."

Then, the third-party firm audits the firestop company's product and systems documentation records in conjunction with the company's management system operational policies and procedures to verify company compliance. An audit also takes place on a project site to verify that the management system is working.

Where the configuration of a penetrating item or group of items is such that a listed system is determined to be nonexistent and reconfiguration of the penetrations or fire resistance–rated assembly is determined to be impractical or impossible, alternative methods for maintaining the integrity of the required fire resistance rating of the assembly should be permitted to be established using an engineering analysis based on a comparison of listed systems prepared by a manufacturer's technical representative of the systems specified, by the laboratory that conducted the original test, or by a professional engineer.

ASTM E 2174, *Standard Practice for On-Site Inspection of Installed Fire Stops,* provides guidance for the inspection of through-penetration firestop systems tested in accordance with ASTM E 814, *Standard Test Method for Fire Tests of Through-Penetration Fire Stops*, and ANSI/UL 1479, *Standard for Fire Tests of Through-Penetration Firestops*.

Independent inspection paid for by the owner is in many specifications and referenced in this appendix using ASTM E 2174 and ASTM E 2393, *Standard Practice for On-Site Inspection of Installed Fire Resistive Joint Systems and Perimeter Fire Barriers*. As a result, there is an accreditation program available for firestop special inspection agencies.

A.8.3.5.6.3(1)(c) Criteria associated with fireblocking can be found in 8.14.2 of *NFPA 5000, Building Construction and Safety Code*.

A.8.3.6.5 Materials used to protect joints become systems when installed to the listed joint system design from an accredited testing laboratory. Installation of joint materials to the listed system should meet all limitations of the system.

There are management system–based contractor approval or qualification programs offered by third-party, independent companies that quantifiably qualify a company to install firestop materials that become systems after proper installation. In each program, there is an industry firestop exam that gives the company a basis to appoint a "Designated Responsible Individual."

Then, the third-party firm audits the firestop company's product and systems documentation records in conjunction with the company's management system operational policies and procedures to verify company compliance. An audit also takes place on a project site to verify that the management system is working.

Where the configuration of a joint is such that a listed system is determined to be nonexistent and reconfiguration of the joint or fire resistance–rated assembly is determined to be impractical or impossible, alternative methods for maintaining the integrity of the required fire resistance rating of the assembly should be permitted to be established using an engineering analysis based on a comparison of listed systems prepared by a manufacturer's technical representative of the systems specified, by the laboratory that conducted the original test, or by a professional engineer.

On-site inspection of firestopping is important in maintaining the integrity of any vertical or horizontal fire barrier. Two standard practice documents were developed with the ASTM process to allow inspections of through-penetration firestops, joints, and perimeter fire barrier systems. ASTM E 2393, *Standard Practice for On-Site Inspection of Installed Fire Resistive Joint Systems and Perimeter Fire Barriers*, provides guidance for the inspection of fire-resistive joints and perimeter fire barrier joint systems tested in accordance with the requirements of ASTM E 1966, *Standard Test Method for Fire-Resistive Joint Systems*, or with ANSI/UL 2079, *Standard for Tests for Fire Resistance of Building Joint Systems*. ASTM E 2393 contains a standardized report format, which would lead to greater consistency for inspections.

Independent inspection paid for by the owner is in many specifications and referenced in this appendix using ASTM E 2393. As a result, there is an accreditation program available for firestop special inspection agencies.

A.8.3.6.7 The provisions of 8.3.6.7 are intended to restrict the interior vertical passage of flame and hot gases from one floor to another at the location where the floor intersects the exterior wall assembly. The requirements of 8.3.6.7 mandate sealing the opening between a floor and an exterior wall assembly to provide the same fire performance as that required for the floor. ASTM E 2307, *Standard Test Method for Determining Fire Resistance of Perimeter Fire Barrier Systems Using Intermediate-Scale, Multi-Story Test Apparatus*, is a test method for evaluating the performance of perimeter fire barrier systems. Some laboratories have tested and listed perimeter fire barrier systems essentially in accordance with the ASTM method. The ASTM test method evaluates the performance of perimeter fire barrier systems in terms of heat transfer and fire spread inside a building through the floor/exterior wall intersection. The current test method does not assess the ability of perimeter fire barrier systems to prevent the spread of fire from story to story via the exterior. However, some laboratories have included additional temperature measurement criteria in their evaluation of the exterior wall, and also evaluate vision glass breakage, as additional pass/fail criteria in an attempt to at least partially address this leapfrog effect.

A.8.4.1 Although a smoke partition is intended to limit the free movement of smoke, it is not intended to provide an area that would be free of smoke.

A.8.4.2(2) An architectural, exposed, suspended-grid acoustical tile ceiling with penetrations for sprinklers, ducted HVAC supply and return-air diffusers, speakers, and recessed light fixtures is capable of limiting the transfer of smoke.

A.8.4.3.4 Gasketing of doors should not be necessary, as the clearances in NFPA 80, *Standard for Fire Doors and Other Opening Protectives*, effectively achieve resistance to the passage of smoke if the door is relatively tight-fitting.

A.8.4.6.2 An air-transfer opening, as defined in NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*, is an opening designed to allow the movement of environmental air between two contiguous spaces.

A.8.5.1 Wherever smoke barriers and doors therein require a degree of fire resistance, as specified by requirements in the various occupancy chapters (Chapters 12 through 42), the construction should be a fire barrier that has been specified to limit the spread of fire and restrict the movement of smoke.

Although a smoke barrier is intended to restrict the movement of smoke, it might not result in tenability throughout the adjacent smoke compartment. The adjacent smoke compartment should be safer than the area on the fire side, thus allowing building occupants to move to that area. Eventually, evacuation from the adjacent smoke compartment might be required.

A.8.5.2 To ensure that a smoke barrier is continuous, it is necessary to seal completely all openings where the smoke barrier abuts other smoke barriers, fire barriers, exterior walls, the floor below, and the floor or ceiling above. It is not the intent to prohibit a smoke barrier from stopping at a fire barrier if the fire barrier meets the requirements of a smoke barrier (i.e., the fire barrier is a combination smoke barrier/fire barrier).

A.8.5.4.1 For additional information on the installation of smoke control door assemblies, see NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*.

A.8.5.4.4 Where, because of operational necessity, it is desired to have smoke barrier doors that are usually open, such doors should be provided with hold-open devices that are activated to close the doors by means of the operation of smoke detectors and other alarm functions.

A.8.6.2 Openings might include items such as stairways; hoistways for elevators, dumbwaiters, and inclined and vertical conveyors; shaftways used for light, ventilation, or building services; or expansion joints and seismic joints used to allow structural movements.

A.8.6.5 The application of the 2-hour rule in buildings not divided into stories is permitted to be based on the number of levels of platforms or walkways served by the stairs.

A.8.6.6(7) Given that a mezzanine meeting the maximum one-third area criterion of 8.6.10.2.1 is not considered a story, it is permitted, therefore, to have 100 percent of its exit access within the communicating area run back through the story below.

A.8.6.7 Where atriums are used, there is an added degree of safety to occupants because of the large volume of space into which smoke can be dissipated. However, there is a need to ensure that dangerous concentrations of smoke are promptly removed from the atrium, and the exhaust system needs careful design. For information about systems that can be used to provide smoke protection in these spaces, see the following:

(1) NFPA 92, *Standard for Smoke Control Systems*
(2) *Principles of Smoke Management*

A.8.6.7(1)(c) The intent of the requirement for closely spaced sprinklers is to wet the atrium glass wall to ensure that the surface of the glass is wet upon operation of the sprinklers, with a maximum spacing of sprinklers of 6 ft (1830 mm) on centers. Provided that it can be shown that the glass can be wet by the sprinklers using a given discharge rate, and that the 6 ft (1830 mm) spacing is not exceeded, the intent of the requirement is met. It is important that the entire glass area surface is wet. Due consideration should be given to the height of the glass panels and any horizontal members that might interfere with sprinkler wetting action.

A.8.6.7(5) See NFPA 92, *Standard for Smoke Control Systems*. The engineering analysis should include the following elements:

(1) Fire dynamics, including the following:
    (a) Fire size and location
    (b) Materials likely to be burning
    (c) Fire plume geometry
    (d) Fire plume or smoke layer impact on means of egress
    (e) Tenability conditions during the period of occupant egress
(2) Response and performance of building systems, including passive barriers, automatic detection and extinguishing, and smoke control
(3) Response time required for building occupants to reach building exits, including any time required to exit through the atrium as permitted by 8.6.7

A.8.6.7(6) Activation of the ventilation system by manual fire alarms, extinguishing systems, and detection systems can cause unwanted operation of the system, and it is suggested that consideration be given to zoning of the activation functions so the ventilation system operates only when actually needed.

A.8.6.9.1(4) The intent of this requirement is to prohibit a communication of two compartments on the same floor via two convenience openings. This is represented in Figure A.8.6.9.1(4).

A.8.6.9.1(6) This requirement prohibits means of egress down or up the convenience opening. It does not prohibit means of escape from running down or up the convenience opening within residential dwelling units.

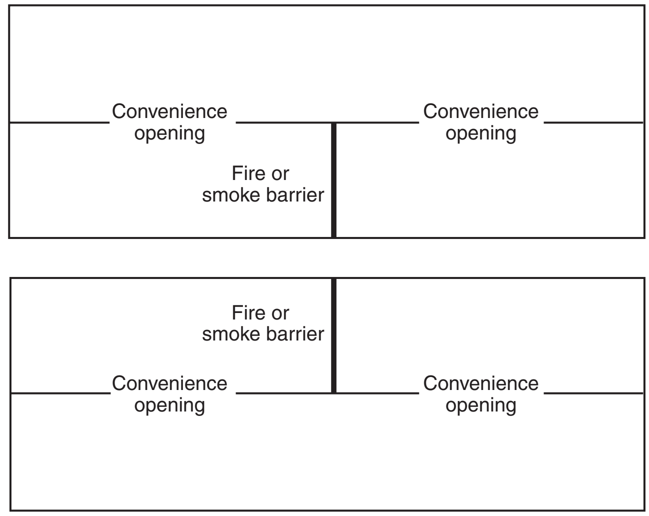

FIGURE A.8.6.9.1(4) Examples of Convenience Openings That Communicate with Two Compartments on Same Floor in Violation of 8.6.9.1(4).

A.8.6.9.2(3) Draftstops protecting vertical openings that are defined in the requirements of NFPA 13, *Standard for the Installation of Sprinkler Systems*, are curtain style descending from the ceiling surface or plane.

A.8.6.9.7(2) The intent is to place a limitation on the size of the opening to which the protection applies. The total floor opening should not exceed twice the projected area of the escalator or moving walk at the floor. Also, the arrangement of the opening is not intended to circumvent the requirements of 8.6.7.

As with any opening through a floor, the openings around the outer perimeter of the escalators should be considered as vertical openings.

A.8.6.11.2(2) See NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*.

A.8.6.11.3 A wood structural panel is a panel manufactured from veneers, or wood strands or wafer, or a combination of veneer and wood strands or wafers bonded together with waterproof synthetic resins or other suitable bonding systems, including composite panels, oriented strand board, and plywood.

A.8.7.1.1 Areas requiring special hazard protection include, but are not limited to, areas such as those used for storage of combustibles or flammables, areas housing heat-producing appliances, or areas used for maintenance purposes.

A.8.7.2 For details, see NFPA 68, *Standard on Explosion Protection by Deflagration Venting*.

A.8.7.3.2 NFPA 58, *Liquefied Petroleum Gas Code*, permits portable butane-fueled appliances in restaurants and in attended commercial food catering operations where fueled by not in excess of two 10 oz (0.28 kg) LP-Gas capacity, nonrefillable butane containers having a water capacity not in excess of 1.08 lb (0.4 kg) per container. Containers are required to be directly connected to the appliance, and manifolding of containers is not permitted. Storage of cylinders is also limited to 24 containers, with an additional 24 permitted where protected by a 2-hour fire resistance–rated barrier.

A.8.7.3.3 The total quantities of flammable liquids in any area should comply with the provisions of other recognized codes, including NFPA 1, *Fire Code*, and NFPA 30, *Flammable and Combustible Liquids Code*. In addition, special consideration should be given to the following:

(1) Obstructions created by the installation of hand-rub solution dispensers
(2) Location of dispensers with regard to adjacent combustible materials and potential sources of ignition, especially where dispensers are mounted on walls of combustible construction
(3) Requirements for other fire protection features, including complete automatic sprinkler protection, to be installed throughout the compartment
(4) Amount and location of the flammable solutions, both in use and in storage, particularly with respect to potential for leakage or failure of the dispenser

A.8.7.5 While the scope of NFPA 99, *Health Care Facilities Code*, is limited to health care occupancies, it is the intent that this requirement be applied to hyperbaric facilities used in all occupancies.

A.8.8 Doors covered by this section include smoke barrier doors, doors in smoke partitions, and doors serving hazardous areas. Paragraph 7.2.1.15 addresses inspection and testing of means of egress doors. Paragraph 8.2.2.4 addresses maintenance of doors required to be smoke leakage. Paragraph 8.3.3.13 addresses the inspection and testing of fire doors.

A.9.4.1 Under certain conditions, elevators are recognized as means of egress.

The use of elevators for emergency evacuation purposes, where operated by trained emergency service personnel (e.g., building personnel, fire personnel), should be incorporated into the building evacuation program. Elevators are normally capable of manual, in-car fire fighter operation (Phase II) after elevator recall (Phase I). In addition, there usually are two or more shafts wherever there are more than three elevators, which further enhances the possibilities for elevator use during an emergency evacuation where operated by trained personnel.

In high-rise buildings, in towers, or in deep underground spaces where travel over considerable vertical distance on stairs can cause persons incapable of such physical effort to collapse before they reach the street exit, stairways are permitted to be used for initial escape from the immediate area of danger, and elevators are permitted to be used to complete the travel to the street.

It can be reasonably assumed that, in all buildings of sufficient height to indicate the need for elevators, elevators will be provided for normal use; for this reason, no requirements for mandatory installation of elevators are included in the *Code*.

For additional information on elevators, see ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators,* and ASME A17.3, *Safety Code for Existing Elevators and Escalators*.

A.9.4.5 Continued operation of solid-state elevator equipment is contingent on maintaining the ambient temperature in the range specified by the elevator manufacturer. If the machine room ventilation/air-conditioning is connected to the general building system, and that system is shut down during a fire, the fire department might lose the use of elevators due to excessive heat in the elevator machine room.

A.9.6.1 The provisions of Section 9.6 cover the basic functions of a complete fire alarm system, including fire detection, alarm, and communications. These systems are primarily intended to provide the indication and warning of abnormal conditions, the summoning of appropriate aid, and the control of occupancy facilities to enhance protection of life.

Some of the provisions of Section 9.6 originated with *NFPA 72, National Fire Alarm and Signaling Code*. For purposes of this *Code*, some provisions of Section 9.6 are more stringent than those of *NFPA 72*, which should be consulted for additional details.

A.9.6.1.4 Records of conducted maintenance and testing and a copy of the certificate of compliance should be maintained.

A.9.6.1.5 A fire watch should at least involve some special action beyond normal staffing, such as assigning an additional security guard(s) to walk the areas affected. Such individuals should be specially trained in fire prevention and in occupant and fire department notification techniques, and they should understand the particular fire safety situation for public education purposes. *(Also see NFPA 601, Standard for Security Services in Fire Loss Prevention.)*

The term *out of service* in 9.6.1.5 is intended to imply that a significant portion of the fire alarm system is not in operation, such as an entire initiating device, signaling line, or notification appliance circuit. It is not the intent of the *Code* to require notification of the authority having jurisdiction, or evacuation of the portion of the building affected, for a single nonoperating device or appliance.

A.9.6.2.5 It is not the intent of 9.6.2.5 to require manual fire alarm boxes to be attached to movable partitions or to equipment, nor is it the intent to require the installation of permanent structures for mounting purposes only.

A.9.6.2.6 The manual fire alarm box required by 9.6.2.6 is intended to provide a means to manually activate the fire alarm system when the automatic fire detection system or waterflow devices are out of service due to maintenance or testing, or where human discovery of the fire precedes automatic sprinkler system or automatic detection system activation. Where the fire alarm system is connected to a monitoring facility, the manual fire alarm box required by 9.6.2.6 should be connected to a separate circuit that is not placed "on test" when the detection or sprinkler system is placed on test. The manual fire alarm box should be located in an area that is accessible to occupants of the building and should not be locked.

A.9.6.2.7 Manual fire alarm boxes can include those with key-operated locks for detention areas or psychiatric hospitals, manual fire alarm boxes in areas where explosive vapors or dusts might be a hazard, or manual fire alarm boxes in areas with corrosive atmospheres. The appearance of manual fire alarm boxes for special uses often differs from those used in areas of normal occupancy. Manual fire alarm boxes, such as those with locks, that are located in areas where the general public has limited access might need to have signage advising persons to seek assistance from staff in the event a fire is noted.

A.9.6.2.10.3 *NFPA 72, National Fire Alarm and Signaling Code*, mandates smoke alarms in all sleeping rooms, and interconnection of smoke alarms is required for both new and existing installations. Per 9.6.2.10.1, the residential occupancy chapters determine whether smoke alarms are needed within sleeping rooms. Paragraph 9.6.2.10.3 limits the requirement for interconnection of smoke alarms to those in new construction. This *Code* does not intend to require compliant, existing smoke alarm installations to be interconnected. This *Code* is periodically revised to add retrospective requirements only where the need is clearly substantiated.

A.9.6.2.10.4 As per annex material located in A.29.5.1 of *NFPA 72*, it is not normally recommended that smoke alarms or smoke detectors be placed in kitchen spaces. This section of the code provides guidelines for safe installation if a need exists to install a smoke alarm or smoke detector in a residential kitchen space or cooking area.

Within this *Code* section, a fixed cooking appliance is any appliance that is intended to be permanently connected electrically to the wiring system or the fuel source. A stationary cooking appliance is any appliance that is intended to be fastened in place or located in a dedicated space and is connected to the supply circuit or fuel source.

Smoke alarms and smoke detectors that are currently available to consumers are susceptible to particles released into the air during normal cooking procedures. If smoke alarms and smoke detectors are placed too close to the area where the cooking source originates, a high level of nuisance alarms can occur. Frequent nuisance alarms can result in an occupant disabling the smoke alarm or smoke detector.

Nuisance alarm studies show that commercially available residential smoke alarms and smoke detectors are susceptible to nuisance alarms when installed too close to cooking appliances. As the horizontal distance between the smoke alarm or smoke detectors and the cooking appliance increases, the frequency of nuisance alarms decreases. Smoke alarms or smoke detectors that use ionization smoke detection have been shown to be more susceptible to cooking nuisance alarms than those that use photoelectric smoke detection when the alarms or detectors are installed within 10 ft (3.0 m) along a horizontal smoke travel path from a cooking appliance. Smoke alarms or smoke detectors that use photoelectric smoke detection produce nuisance alarms when installed less than 10 ft (3.0 m) from a cooking appliance, though to a lesser degree.

The occurrence of the higher frequency of nuisance alarms observed in smoke alarms or smoke detectors that use ionization detection have been documented in the fire research data. Due to the differences in technology between ionization detection and photoelectric detection, the sensitivity typically used for ionization detection is much higher than that used for photoelectric detection. This sensitivity difference is a result of each type of the detection being required to satisfy UL 217, *Single and Multiple Station Smoke Alarms*, performance tests. Removing detection technology from consideration, the frequency of nuisance alarms is solely due to the sensitivity of the detection method used. Thus, both ionization and photoelectric detector technologies will produce nuisance alarms due to cooking, but currently available smoke alarms and smoke detectors that use ionization detection typically produce more cooking related nuisance alarms.

The higher sensitivities of currently available smoke alarms and smoke detectors that use ionization detection do provide a benefit at the expense of a potentially higher rate of cooking-related nuisance alarms. Research has demonstrated that ionization detection will typically respond faster than photoelectric detection to flaming fires, providing earlier warning to occupants that might allow for quicker intervention or faster egress. In general, the installation of smoke alarms or smoke detectors that use ionization detection will result in increased fire safety at the risk of a higher frequency of nuisance alarms. The installation of smoke alarms or smoke detectors that use photoelectric detection will result in reduced fire safety for flaming fires and a reduced risk of nuisance alarms. Based on the trade-off between faster response to fires and the frequency of nuisance alarms, detectors that utilize both technologies (i.e., ionization, photoelectric, and a combination) are allowed to be installed between 10 ft (3.0 m) and 20 ft (6.1 m) along a horizontal flow path from a standard or fixed cooking appliance if the specific detector is equipped with an alarm silencing means or is of the photoelectric type. Nuisance alarm studies provide data on cooking nuisances that emanate from both fixed cooking appliances and stationary cooking appliances (e.g., stove, oven) as well as portable cooking appliances (e.g., toaster). Based on these studies, which demonstrate the potential of all cooking appliances to generate nuisance sources, a zone of exclusion has been specified surrounding each stationary or fixed cooking appliance. The purpose of this zone is to limit the installation of smoke alarms and detectors in areas where stationary, fixed, or portable cooking appliances will be located within the residential kitchen space such that potential nuisance alarms are minimized. The size of the zone of exclusion is specified to attempt to take into account the unknown and transitory locations of portable cooking appliances. This zone of exclusion is determined by measuring a 10 ft (3.0 m) radial distance from the closest edge of a stationary or fixed cooking appliance. The zone of exclusion is not intended to pass through walls or doorways. Figure A.9.6.2.10.4(a) provides an example of the zone of exclusion in a generalized residential kitchen. If other areas of this *Code* require that a smoke alarm or smoke detector be placed within a horizontal flow path distance between 10 ft (3.0 m) and 20 ft (6.1 m) from a stationary or fixed cooking appliance, the following method should be used to determine the distance, and only photoelectric detection or smoke alarms/detectors with alarm silencing means can be installed in this area.

To install a smoke alarm or detector between 10 ft (3.0 m) and 20 ft (6.1 m) from the cooking appliance, an installer must first determine the 10 ft (3.0 m) area of exclusion. Once the area of exclusion is determined, an installer must then determine the horizontal flow distance. This is the horizontal distance along the ceiling from the closest edge of the cooking appliance to the smoke alarm or detector. The horizontal distance can consist of line segments due to impediments, such as interior partitions.

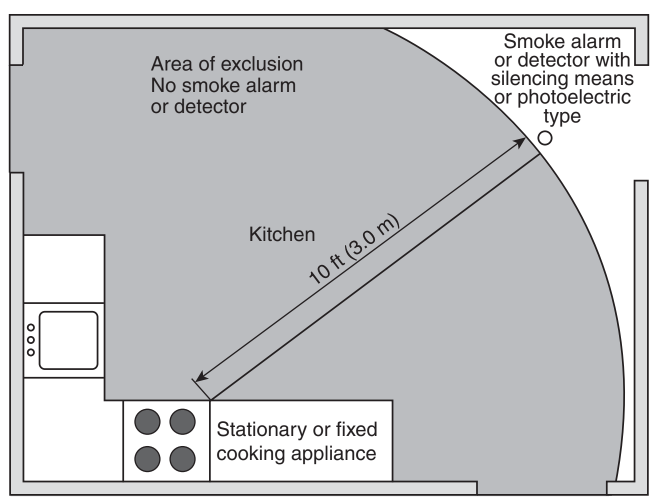

FIGURE A.9.6.2.10.4(a) Example of Zone of Exclusion (gray area) Within Typical Residential Kitchen. [72: Figure A.29.8.3.4(4)(a)]

Once an impediment is met, the measurement of the distance will then continue along the new horizontal path segment until the distance requirement is met or another impediment is encountered. Figure A.9.6.2.10.4(b) provides an example for placement outside a kitchen in a nearby hallway. Figure A.9.6.2.10.4(c) provides another example of appropriate placement outside of a kitchen in an adjacent room. At a horizontal flow path distance of greater than 20 ft (6.1 m), any type of smoke alarm or smoke detector can be installed. In rare cases, a residential dwelling can be of such size and configuration that an area of exclusion of 10 ft (3.0 m) from a stationary or fixed cooking appliance excludes the placement of a smoke alarm or smoke detector required by other areas of this *Code*. In these cases, a smoke alarm or smoke detector using photoelectric detection can be installed at least 72 in. (1.83 m) from the fixed or stationary cooking appliance. Figure A.9.6.2.10.4(d) provides an example of this situation in practice where a smoke alarm or smoke detector is required outside of the sleeping area but the space is in close proximity to the kitchen space. [**72:** A.29.8.3.4(4)]

A.9.6.2.10.5 Studies indicate that smoke alarms and smoke detectors that use ionization detection, photoelectric detection, or a combination of ionization and photoelectric detection are susceptible to nuisance alarms caused by steam. Little research has been done on the comparative response of these types of detection to steam. Steam particles, in general, are visible, reflect light easily, and are typically produced in a size range that would be more likely to activate a photoelectric sensor. Thus, it is required that smoke alarms and smoke detectors be installed greater than 36 in. (910 mm) from the bathroom door where possible. Increasing the distance between the smoke alarm or smoke detector and the bathroom door can reduce the frequency of nuisance alarms from bathroom steam. Frequent nuisance alarms can result in the occupant disabling the smoke alarm. Each incremental increase in separation, up to 10 ft (3.0 m), between the bathroom door and the smoke alarm or smoke detector is expected to reduce the frequency of nuisance alarms. [**72:** A.29.8.3.4(5)]

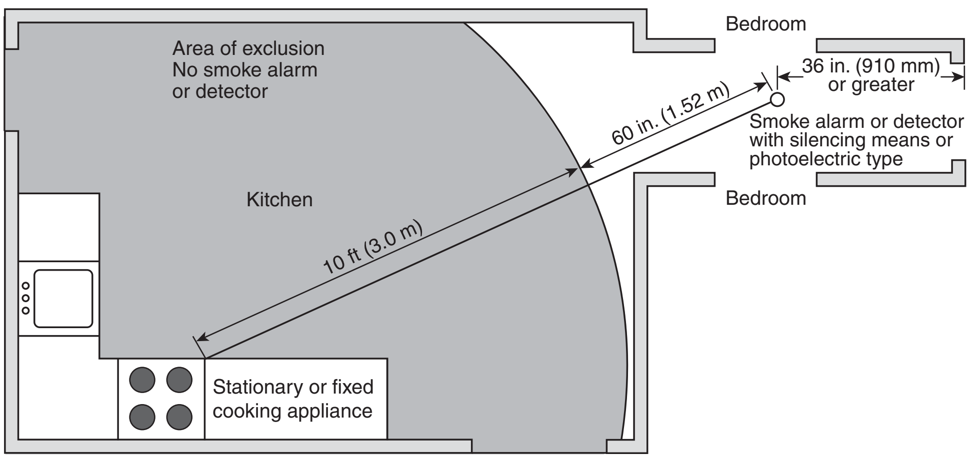

FIGURE A.9.6.2.10.4(b) Example of Smoke Alarm or Smoke Detector Placement Between 10 ft (3.0 m) and 20 ft (6.1 m) Away in Hallway from Center of Stationary or Fixed Cooking Appliance. [72: Figure A.29.8.3.4(4)(b)]

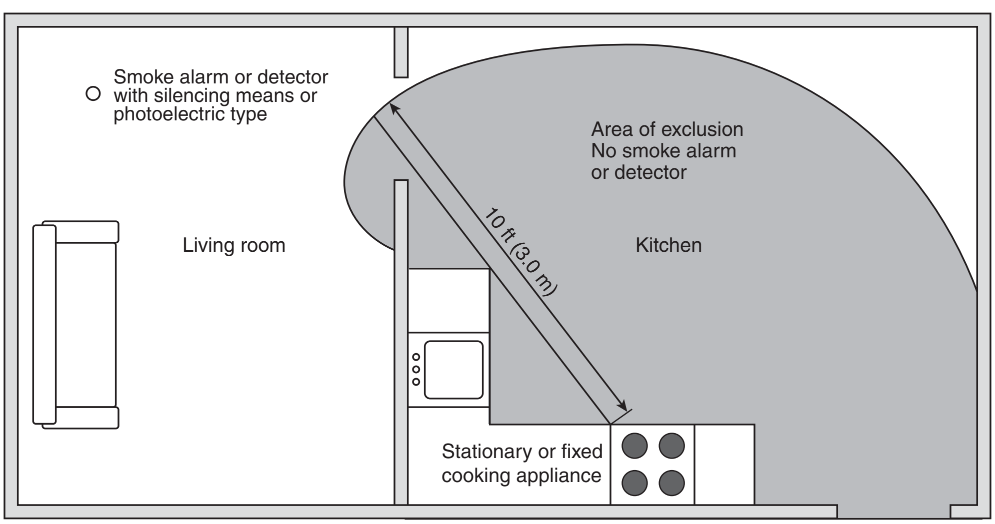

FIGURE A.9.6.2.10.4(c) Example of Smoke Alarm or Smoke Detector Placement Between 10 ft (3.0 m) and 20 ft (6.1 m) Away in Hallway from Center of Stationary or Fixed Cooking Appliance. [72: Figure A.29.8.3.4(4)(c)]

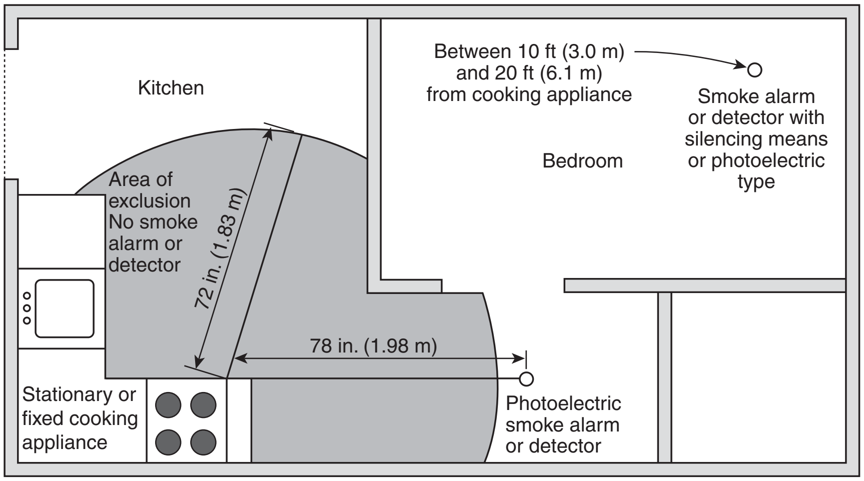

FIGURE A.9.6.2.10.4(d) Example of Exception Placement of Photoelectric Smoke Alarm or Smoke Detector at 72 in. (1.83 m) from Stationary or Fixed Cooking Appliance. [72: Figure A.29.8.3.4(4)(d)]

A.9.6.2.10.8 A dwelling unit is that structure, area, room, or combination of rooms, including hotel rooms/suites, in which a family or individual lives. A dwelling unit includes living areas only and not common usage areas in multifamily buildings, such as corridors, lobbies, and basements.

A.9.6.3.2.1 Elevator lobbies have been considered areas subject to unwanted alarms due to factors such as low ceilings and smoking. In the past several years, new features have become available to reduce this problem. These features are, however, not necessarily included in any specific installation.

A.9.6.3.2.2 The concept addressed is that detectors used for releasing service, such as door or damper closing and fan shutdown, are not required to sound the building alarm.

A.9.6.3.2.3 The concept addressed is that detectors used for releasing service, such as door or damper closing and fan shutdown, are not required to sound the building alarm.

A.9.6.3.5.7 Visual notification appliances installed in large-volume spaces, such as arenas, stadiums, malls, and atriums, can be alternative devices that are not listed as visible notification appliances for fire alarm systems, provided that the notification objective of the visual signal is reasonably achieved. Examples of alternative devices include, but are not limited to, scoreboards, message boards, and other electronic devices that meet the performance objectives of visible fire alarm appliances in large-volume spaces.

It is the intent to permit the omission of visible notification appliances as identified in 9.6.3.5.7, provided that the adjacent areas that have not been specifically designated as exempt are provided with visible notification as required by 9.6.3.5.

A.9.6.3.5.8 Documentation should be maintained with the as-built drawings so that inspection and testing personnel understand that the visible appliances have been exempted from certain areas and, therefore, can note the deviation on the acceptance test documentation and ongoing inspection reports. This will provide inspection and testing personnel with necessary details regarding the omission of visible notification appliances.

A.9.6.3.6.2 To approve an evacuation plan to selectively notify building occupants, the authority having jurisdiction should consider several building parameters, including building compartmentation, detection and suppression system zones, occupant loads, and the number and arrangement of the means of egress.

In high-rise buildings, it is typical to evacuate the fire floor, the floor(s) above, and the floor immediately below. Other areas are then evacuated as the fire develops.

A.9.6.3.9.2 The provisions of 9.6.3.9.2 offer an alternative to the emergency voice alarm and communications system provisions (live voice or recorded voice announcements) of *NFPA 72, National Fire Alarm and Signaling Code*. Occupancies such as large-venue assembly occupancies and mercantile mall buildings are occupancies in which the physical configuration (e.g., large-volume spaces), function, and human behavior (including elevated levels of occupant-generated noise) present challenges with respect to effective occupant notification by standard means in accordance with *NFPA 72*. Because the routine operation of these occupancies demands highly reliant, acoustically capable, and sufficiently audible public address systems, properly trained staff can be relied on to use these public address systems to effect occupant evacuation, relocation, or both.

As 9.6.3.9.2 specifically permits an alternative means of notification to that prescribed by *NFPA 72*, it does not mandate that the secondary power supply and the intelligibility and audibility facets of the public address system comply with *NFPA 72* or suggest that equivalency with the related provisions of *NFPA 72* is required. However, it is anticipated that, when approving the secondary power and audibility capabilities of public address systems, authorities having jurisdiction will ensure that these systems are conceptually comparable to the emergency voice alarm and communications system provisions of *NFPA 72*, such that a reliable and effective occupant notification system is provided.

A.9.7.1.1 For a discussion of the effectiveness of automatic sprinklers, as well as a general discussion of automatic sprinklers, see the NFPA *Fire Protection Handbook*. Where partial sprinkler protection is permitted by another section of this *Code*, the limited area systems provisions of NFPA 13, *Standard for the Installation of Sprinkler Systems*, should apply.

A.9.7.1.4 Properly designed automatic sprinkler systems provide the dual function of both automatic alarms and automatic extinguishment. Dual function is not provided in those cases where early detection of incipient fire and early notification of occupants are needed to initiate actions in behalf of life safety earlier than can be expected from heat-sensitive fire detectors.

A.9.7.2.1 *NFPA 72, National Fire Alarm and Signaling Code*, provides details of standard practice in sprinkler supervision. Subject to the approval of the authority having jurisdiction, sprinkler supervision is also permitted to be provided by direct connection to municipal fire departments or, in the case of very large establishments, to a private headquarters providing similar functions. *NFPA 72* covers such matters. System components and parameters that are required to be monitored should include, but should not be limited to, control valves, water tank levels and temperatures, tank pressure, and air pressure on dry-pipe valves.

Where municipal fire alarm systems are involved, reference should also be made to NFPA 1221, *Standard for the Installation, Maintenance, and Use of Emergency Services Communications Systems.*

A.9.8.1 There are typically two different ways that extinguishing systems other than fire sprinkler systems are used. The first is when the entire building is protected with one of these alternate systems. When this is the case, the exceptions, reductions, and alternative code provisions that are offered as options when fire sprinkler systems are installed should not be granted to the other extinguishing system unless the other system has demonstrated the same temperature control during a fire and reliability of operation as a fire sprinkler system. Reliability of operation needs to extend to the long-term use of the other system and an analysis of the reliability of the component parts. Some component of other extinguishing systems can show reliability data from their use in systems outside of fire protection where they get exercised on a regular basis, but acceptance on this basis is cautioned because many mechanical parts that sit for a long time without being exercised, as fire protection systems need to do, might not have the same reliability. A reliability analysis should also take into account inspection, testing, and maintenance criteria and the likelihood of a building owner knowing and understanding what needs to be performed to keep the other system operational.

The second manner in which other systems are used as alternatives to fire sprinkler systems are in individual rooms or spaces of otherwise sprinklered occupancies. Here the authority having jurisdiction needs to use some judgment in the application of exceptions, reductions, and alternative code provisions that are offered for sprinklered occupancies. The permission to utilize such exceptions, reductions, and alternative code provisions far from the space with the other fire protection system should be granted. Closer to the space with the alternate system, exceptions, reductions, and alternate code provisions for sprinklers could be granted if the system was analyzed as discussed above and found to be equivalent to a fire sprinkler system.

A.9.9 For a description of standard types of extinguishers and their installation, maintenance, and use, see NFPA 10, *Standard for Portable Fire Extinguishers.* The labels of recognized testing laboratories on extinguishers provide evidence of tests indicating the reliability and suitability of the extinguisher for its intended use. Many unlabeled extinguishers are offered for sale that are substandard by reason of insufficient extinguishing capacity, questionable reliability, or ineffective extinguishing agents for fires in ordinary combustible materials or because they pose a personal hazard to the user.

A.10.2 The requirements pertaining to interior finish are intended to restrict the spread of fire over the continuous surface forming the interior portions of a building.

Table A.10.2 shows the fire test methods and classification criteria that apply to different interior finish materials.

Table A.10.2 Fire Testing of Interior Finish Materials

Material	Test Method	Acceptance Criterion	Application Requirement	Section
Interior wall and ceiling finish materials, except as shown in this table	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	As required by relevant sections	10.2.3
	ASTM E 84 or ANSI/UL 723	Class B, in accordance with 10.2.3.4(2)	As required by relevant sections	10.2.3
	ASTM E 84 or ANSI/UL 723	Class C, in accordance with 10.2.3.4(3)	As required by relevant sections	10.2.3
	NFPA 286	In accordance with 10.2.3.7.2	Permitted where Class A, B, or C is required by relevant sections	10.2.3.2
Materials having thickness $<\frac{1}{28}$ in. (<0.90 mm) applied directly to a noncombustible or limited-combustible surface of walls or ceilings	No testing required			10.2.1.2
Exposed portions of structural members complying with requirements for buildings of Type IV (2HH) construction in accordance with NFPA 220	No testing required			10.2.3.1

(continues)

Table A.10.2 ***Continued***

Material	Test Method	Acceptance Criterion	Application Requirement	Section
Cellular or foamed plastics (exposed foamed plastics and foamed plastics used in conjunction with textile or vinyl facing or cover)	NFPA 286	In accordance with 10.2.3.7.2	Permitted where Class A, B, or C is required by relevant sections	10.2.4.3.1.1(1)
	ANSI/UL 1715	Pass	Permitted where Class A, B, or C is required by relevant sections	10.2.4.3.1.1(2)
	ANSI/UL 1040	Pass	Permitted where Class A, B, or C is required by relevant sections	10.2.4.3.1.1(3)
	FM 4880	Pass	Permitted where Class A, B, or C is required by relevant sections	10.2.4.3.1.1(4)
	Suitable large-scale fire test that substantiates combustibility characteristics for use intended under actual fire conditions	Pass	Permitted where Class A, B, or C is required by relevant sections	10.2.4.3.1
Textile wall coverings	NFPA 286	In accordance with 10.2.3.7.2	Permitted where Class A, B, or C is required by relevant sections	10.2.4.1(6)
	NFPA 265, Method B	In accordance with 10.2.3.7.1	Permitted on walls and partitions	10.2.4.1(5)
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	Permitted on walls, but also requires sprinklers per Section 9.7	10.2.4.1(1)
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	Permitted on partitions not exceeding three-quarters of the floor-to-ceiling height or not exceeding 8 ft (2440 mm) in height, whichever is less	10.2.4.1(2)
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	Permitted to extend not more than 48 in. (1220 mm) above finished floor on ceiling-height walls and ceiling-height partitions	10.2.4.1(3)
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	Previously approved existing installations of textile material meeting the requirements of Class A permitted to be continued to be used	10.2.4.1(4)
Expanded vinyl wall coverings	NFPA 286	In accordance with 10.2.3.7.2	Permitted where Class A, B, or C is required by relevant sections	10.2.4.2(6)
	NFPA 265, Method B	In accordance with 10.2.3.7.1	Permitted on walls and partitions	10.2.4.2(5)
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	Permitted on walls, but also requires sprinklers per Section 9.7	10.2.4.2(1)

Table A.10.2 ***Continued***

Material	Test Method	Acceptance Criterion	Application Requirement	Section
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	Permitted on partitions not exceeding three-quarters of the floor-to-ceiling height or not exceeding 8 ft (2440 mm) in height, whichever is less	10.2.4.2(2)
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4 (1)	Permitted to extend not more than 48 in. (1220 mm) above finished floor on ceiling-height walls and ceiling-height partitions	10.2.4.2(3)
	ASTM E 84 or ANSI/UL 723	Class A, B, or C, in accordance with 10.2.3.4	Existing installations of materials with appropriate wall finish classification for occupancy involved, and with classification in accordance with the provisions of 10.2.3.4	10.2.4.2(4)
Textile ceiling coverings	NFPA 286	In accordance with 10.2.3.7.2	Permitted where Class A, B, or C is required by relevant sections	10.2.4.1(6)
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	Permitted on walls, but also requires sprinklers per Section 9.7	10.2.4.1(1)
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	Previously approved existing installations of textile material meeting the requirements of Class A permitted to be continued to be used	10.2.4.1(4)
Expanded vinyl ceiling coverings	NFPA 286	In accordance with 10.2.3.7.2	Permitted where Class A, B, or C is required by relevant sections	10.2.4.2(6)
	ASTM E 84 or ANSI/UL 723	Class A, in accordance with 10.2.3.4(1)	Permitted on walls, but also requires sprinklers per Section 9.7	10.2.4.2(1)
	ASTM E 84 or ANSI/UL 723	Class A, B, or C, in accordance with 10.2.3.4	Existing installations of materials with appropriate wall finish classification for occupancy involved, and with classification in accordance with the provisions of 10.2.3.4	10.2.4.2(4)
Interior trim, other than foamed plastic and other than wall base	ASTM E 84 or ANSI/UL 723	Class C, in accordance with 10.2.3.4	Interior wall and ceiling trim and incidental finish, other than wall base not in excess of 10 percent of the specific wall and ceiling areas of any room or space to which it is applied where interior wall and ceiling finish of Class A or Class B is required	10.2.5.1
	NFPA 286	In accordance with 10.2.3.7.2	Permitted where Class A, B, or C is required by relevant sections	10.2.3.2

(continues)

Table A.10.2 ***Continued***

Material	Test Method	Acceptance Criterion	Application Requirement	Section
Foamed plastic used as interior trim	ASTM E 84 or ANSI/UL 723	Flame spread index = 75	(1) Minimum density of interior trim required to be 20 lb/ft^3 (320 kg/m^3)	10.2.4.3.2
			(2) Maximum thickness of interior trim required to be ½ in. (13 mm), and maximum width required to be 4 in. (100 mm)	10.2.4.3.2
			(3) Interior trim not permitted to constitute more than 10 percent of the specific wall or ceiling area of a room or space to which it is applied	10.2.4.3.2
	NFPA 286	In accordance with 10.2.3.7.2	Permitted where Class A, B, or C is required by relevant sections	10.2.3.2
Fire-retardant coatings	NFPA 703	Class A, B, or C, when tested by ASTM E 84 or ANSI/UL 723, in accordance with 10.2.3.4	Required flame spread index or smoke developed index values of existing surfaces of walls, partitions, columns, and ceilings permitted to be secured by applying approved fire-retardant coatings to surfaces having higher flame spread index values than permitted; such treatments required to be tested or listed and labeled for application to material to which they are applied	10.2.6.1
Factory-applied fire-retardant–coated assemblies (listed and labeled)	ASTM E 2768 on the coated surface	Pass	Surfaces of walls. partitions, columns, and ceilings in new construction	10.2.6.2
Carpet and carpetlike interior floor finishes	ASTM D 2859	Pass	All areas	10.2.7.1
Floor coverings, other than carpet, judged to represent an unusual hazard (excluding traditional finish floors and floor coverings, such as wood flooring and resilient floor coverings)	NFPA 253	Critical radiant flux = 0.1 W/cm^2	All areas	10.2.7.2
Interior floor finish, other than carpet and carpetlike materials	NFPA 253	Class I: Critical radiant flux = 0.45 W/cm^2, in accordance with 10.2.7.4	As required by relevant sections	10.2.7.3
	NFPA 253	Class II: Critical radiant flux = 0.22 W/cm^2, in accordance with 10.2.7.4	As required by relevant sections	10.2.7.3
Wall base [interior floor trim material used at junction of wall and floor to provide a functional or decorative border, and not exceeding 6 in. (150 mm) in height]	NFPA 253	Class II: Critical radiant flux = 0.22 W/cm^2, in accordance with 10.2.7.4	All areas	10.2.5.2
	NFPA 253	Class I: Critical radiant flux = 0.45 W/cm^2, in accordance with 10.2.7.4	If interior floor finish is required to meet Class I critical radiant flux	10.2.5.2
Floor finish of traditional type, such as wood flooring and resilient floor coverings	No testing required			10.2.2.2

A.10.2.1 The requirements pertaining to interior finish are intended to restrict the spread of fire over the continuous surface forming the interior portions of a building. The presence of multiple paint layers has the potential for paint delamination and bubbling or blistering of paint. Testing (NFPA *Fire Technology*, August 1974, "Fire Tests of Building Interior Covering Systems," David Waksman and John Ferguson, Institute for Applied Technology, National Bureau of Standards) has shown that adding up to two layers of paint with a dry film thickness of about 0.007 in. (0.18 mm) will not change the fire properties of surface-covering systems. Testing has shown that the fire properties of the surface-covering systems are highly substrate dependent and that thin coatings generally take on the characteristics of the substrate. When exposed to fire, the delamination, bubbling, and blistering of paint can result in an accelerated rate of flame spread.

A.10.2.1.5 Such partitions are intended to include washroom water closet partitions.

A.10.2.2 Table A.10.2.2 provides a compilation of the interior finish requirements of 7.1.4 and the occupancy chapters (Chapters 12 through 42) of this *Code*.

A.10.2.2.2 This paragraph recognizes that traditional finish floors and floor coverings, such as wood flooring and resilient floor coverings, have not proved to present an unusual hazard.

A.10.2.3 ASTM E 84, *Standard Test Method of Surface Burning Characteristics of Building Materials*, and UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, are considered nationally recognized consensus standard test methods for determining the flame spread index and smoke developed index of building materials and are likely to yield equivalent test results. *(See also A.10.2.4.1.)*

A.10.2.3.4 It has been shown that the method of mounting interior finish materials usually affects actual performance. The use of standard mounting methods will be helpful in determining appropriate fire test results. Where materials are tested in intimate contact with a substrate to determine a classification, such materials should be installed in intimate contact with a similar substrate. Such details are especially important for "thermally thin" materials. For further information, see ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*.

Some interior wall and ceiling finish materials, such as fabrics not applied to a solid backing, do not lend themselves to a test made in accordance with ASTM E 84. In such cases, the large-scale test outlined in NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*, is permitted to be used. In 1989 the NFPA Technical Committee on Fire Tests eliminated the so-called "small-scale test" from NFPA 701 because the results had been shown not to represent a fire performance that corresponded to what happened in real scale. Since then, NFPA 701 no longer contains a "small-scale test" but it now contains two tests (Test 1 and Test 2), which apply to materials as a function of their areal density. Thus NFPA 701 Test 1 applies to fabrics (other than vinyl-coated fabric blackout linings) having an areal density less than or equal to 21 oz/yd^2 (700 g/m^2), while NFPA 701 Test 2 applies to fabrics with an areal density greater than 21 oz/yd^2 (700 g/m^2), vinyl-coated fabric blackout linings, decorative objects, and films. Representations that materials or products have been tested to the small-scale test in NFPA 701 normally refer to the pre-1989 small-scale test, which no longer exists and which does not represent acceptable fire performance.

Prior to 1978, the test report described by ASTM E 84 included an evaluation of the fuel contribution as well as the flame spread index and the smoke developed index. However, it is now recognized that the measurement on which the fuel contribution is based does not provide a valid measure. Therefore, although the data are recorded during the test, the information is no longer normally reported. Classification of interior wall and ceiling finish thus relies only on the flame spread index and smoke developed index.

The 450 smoke developed index limit is based solely on obscuration. *(See A.10.2.4.1.)*

A.10.2.3.7 The methodology specified in NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile or Expanded Vinyl Wall Coverings on Full Height Panels and Walls*, includes provisions for measuring smoke obscuration. Such measurement is considered desirable, but the basis for specific recommended values is not currently available. *(See A.10.2.4.1.)*

A.10.2.3.7.1 See A.10.2.3.7 and A.10.2.4.1.

A.10.2.4 Surface nonmetallic raceway products, as permitted by *NFPA 70*, *National Electrical Code*, are not interior finishes and are not subject to the provisions of Chapter 10.

A.10.2.4.1 Previous editions of the *Code* have regulated textile materials on walls and ceilings using ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*. Full-scale room/corner fire test research has shown that flame spread indices produced by ASTM E 84 or ANSI/UL 723 might not reliably predict all aspects of the fire behavior of textile wall and ceiling coverings.

NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile or Expanded Vinyl Wall Coverings on Full Height Panels and Walls*, and NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*, both known as room/corner tests, were developed for assessing the fire and smoke obscuration performance of textile wall coverings and interior wall and ceiling finish materials, respectively. As long as an interior wall or ceiling finish material is tested by NFPA 265 or NFPA 286, as appropriate, using a mounting system, substrate, and adhesive (if appropriate) that are representative of actual use, the room/corner test provides an adequate evaluation of a product's flammability and smoke obscuration behavior. Manufacturers, installers, and specifiers should be encouraged to use NFPA 265 or NFPA 286, as appropriate — but not both — because each of these standard fire tests has the ability to characterize actual product behavior, as opposed to data generated by tests using ASTM E 84 or ANSI/UL 723, which only allow comparisons of one product's performance with another. If a manufacturer or installer chooses to test a wall finish in accordance with NFPA 286, additional testing in accordance with ASTM E 84 or ANSI/UL 723 is not necessary.

The test results from ASTM E 84 or ANSI/UL 723 are suitable for classification purposes but should not be used as input into fire models, because they are not generated in units suitable for engineering calculations. Actual test results for heat, smoke, and combustion product release from NFPA 265, and from NFPA 286, are suitable for use as input into fire models for performance-based design.

Table A.10.2.2 Interior Finish Classification Limitations

Occupancy	Exits	Exit Access Corridors	Other Spaces
Assembly — New			
>300 occupant load	A	A or B	A or B
	I or II	I or II	NA
≤300 occupant load	A	A or B	A, B, or C
	I or II	I or II	NA
Assembly — Existing			
>300 occupant load	A	A or B	A or B
≤300 occupant load	A	A or B	A, B, or C
Educational — New	A	A or B	A or B; C on low partitions†
	I or II	I or II	NA
Educational — Existing	A	A or B	A, B, or C
Day-Care Centers — New	A	A	A or B
	I or II	I or II	NA
Day-Care Centers — Existing	A or B	A or B	A or B
Day-Care Homes — New	A or B	A or B	A, B, or C
	I or II		NA
Day-Care Homes — Existing	A or B	A, B, or C	A, B, or C
Health Care — New	A	A	A
	NA	B on lower portion of corridor wall†	B in small individual rooms†
	I or II	I or II	NA
Health Care — Existing	A or B	A or B	A or B
Detention and Correctional — New (sprinklers mandatory)	A or B	A or B	A, B, or C
	I or II	I or II	NA
Detention and Correctional — Existing	A or B	A or B	A, B, or C
	I or II	I or II	NA
One- and Two-Family Dwellings and Lodging or Rooming Houses	A, B, or C	A, B, or C	A, B, or C
Hotels and Dormitories — New	A	A or B	A, B, or C
	I or II	I or II	NA
Hotels and Dormitories — Existing	A or B	A or B	A, B, or C
	I or II†	I or II†	NA
Apartment Buildings — New	A	A or B	A, B, or C
	I or II	I or II	NA
Apartment Buildings — Existing	A or B	A or B	A, B, or C
	I or II†	I or II†	NA
Residential Board and Care — *(See Chapters 32 and 33.)*			
Mercantile — New	A or B	A or B	A or B
	I or II		NA
Mercantile — Existing			
Class A or Class B stores	A or B	A or B	Ceilings — A or B; walls — A, B, or C
Class C stores	A, B, or C	A, B, or C	A, B, or C
Business and Ambulatory Health Care — New	A or B	A or B	A, B, or C
	I or II		NA
Business and Ambulatory Health Care — Existing	A or B	A or B	A, B, or C
Industrial	A or B	A, B, or C	A, B, or C
	I or II	I or II	NA
Storage	A or B	A, B, or C	A, B, or C
	I or II		NA

NA: Not applicable.Notes:

(1) Class A interior wall and ceiling finish — flame spread index, 0–25 (new applications); smoke developed index, 0–450.

(2) Class B interior wall and ceiling finish — flame spread index, 26–75 (new applications); smoke developed index, 0–450.

(3) Class C interior wall and ceiling finish — flame spread index, 76–200 (new applications); smoke developed index, 0–450.

(4) Class I interior floor finish — critical radiant flux, not less than 0.45 W/cm^2.

(5) Class II interior floor finish — critical radiant flux, not more than 0.22 W/cm^2, but less than 0.45 W/cm^2.

(6) Automatic sprinklers — where a complete standard system of automatic sprinklers is installed, interior wall and ceiling finish with a flame spread rating not exceeding Class C is permitted to be used in any location where Class B is required, and Class B interior wall and ceiling finish is permitted to be used in any location where Class A is required; similarly, Class II interior floor finish is permitted to be used in any location where Class I is required, and no interior floor finish classification is required where Class II is required. These provisions do not apply to new detention and correctional occupancies.

(7) Exposed portions of structural members complying with the requirements for heavy timber construction are permitted.

†See corresponding chapters for details.

A.10.2.4.2 Expanded vinyl wall covering consists of a woven textile backing, an expanded vinyl base coat layer, and a non-expanded vinyl skin coat. The expanded base coat layer is a homogeneous vinyl layer that contains a blowing agent. During processing, the blowing agent decomposes, which causes this layer to expand by forming closed cells. The total thickness of the wall covering is approximately 0.055 in. to 0.070 in. (1.4 mm to 1.8 mm).

A.10.2.4.3.1 See A.10.2.4.3.1.2.

A.10.2.4.3.1.2 Both NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*, and ANSI/UL 1715, *Standard for Fire Test of Interior Finish Material*, contain smoke obscuration criteria. ANSI/UL 1040, *Standard for Fire Test of Insulated Wall Construction*, and FM 4880, *Approval Standard for Class I Insulated Wall or Wall and Roof/Ceiling Panels; Plastic Interior Finish Materials; Plastic Exterior Building Panels; Wall/Ceiling Coating Systems; Interior or Exterior Finish Systems*, do not. Smoke obscuration is an important component of the fire performance of cellular or foamed plastic materials.

A.10.2.4.4 Light-transmitting plastics are used for a variety of purposes, including light diffusers, exterior wall panels, skylights, canopies, glazing, and the like. Previous editions of the *Code* have not addressed the use of light-transmitting plastics. Light-transmitting plastics will not normally be used in applications representative of interior finishes. Accordingly, ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials,* can produce test results that might or might not apply.

Light-transmitting plastics are regulated by model building codes such as *NFPA 5000*, *Building Construction and Safety Code*. Model building codes provide adequate regulation for most applications of light-transmitting plastics. Where an authority having jurisdiction determines that a use is contemplated that differs from uses regulated by model building codes, light-transmitting plastics in such applications can be substantiated by fire tests that demonstrate the combustibility characteristics of the light-transmitting plastics for the use intended under actual fire conditions.

For additional information on light transmitting plastics, see Section 48.7 of *NFPA 5000*.

A.10.2.6 Fire-retardant coatings need to be applied to surfaces properly prepared for the material, and application needs to be consistent with the product listing. Deterioration of coatings applied to interior finishes can occur due to repeated cleaning of the surface or painting over applied coatings.

A.10.2.6.1 It is the intent of the *Code* to mandate interior wall and ceiling finish materials that obtain their fire performance and smoke developed characteristics in their original form. However, in renovations, particularly those involving historic buildings, and in changes of occupancy, the required fire performance or smoke developed characteristics of existing surfaces of walls, partitions, columns, and ceilings might have to be secured by applying approved fire-retardant coatings to surfaces having higher flame spread ratings than permitted. Such treatments should comply with the requirements of NFPA 703, *Standard for Fire Retardant–Treated Wood and Fire-Retardant Coatings for Building Materials*. When fire-retardant coatings are used, they need to be applied to surfaces properly prepared for the material, and application needs to be consistent with the product listing. Deterioration of coatings applied to interior finishes can occur due to repeated cleaning of the surface or painting over applied coatings, but permanency must be assured in some appropriate fashion. Fire-retardant coatings must possess the desired degree of permanency and be maintained so as to retain the effectiveness of the treatment under the service conditions encountered in actual use.

A.10.2.6.2 The intent of this section is that factory-applied fire-retardant-coated products, such as panels or tiles applied to walls or ceilings, replace the existing finish and are not applied on top of the existing finish.

A.10.2.7 The flooring radiant panel provides a measure of a floor covering's tendency to spread flames where located in a corridor and exposed to the flame and hot gases from a room fire. The flooring radiant panel test method is to be used as a basis for estimating the fire performance of a floor covering installed in the building corridor. Floor coverings in open building spaces and in rooms within buildings merit no further regulation, provided that it can be shown that the floor covering is at least as resistant to spread of flame as a material that meets the U.S. federal flammability standard 16 CFR 1630, "Standard for the Surface Flammability of Carpets and Rugs" (FF 1-70). All carpeting sold in the United States since 1971 is required to meet this standard and, therefore, is not likely to become involved in a fire until a room reaches or approaches flashover. Therefore, no further regulations are necessary for carpet, other than carpet in exitways and corridors.

It has not been found necessary or practical to regulate interior floor finishes on the basis of smoke development.

Full-scale fire tests and fire experience have shown that floor coverings in open building spaces merit no regulation beyond the U.S. federally mandated DOC FF 1-70 "pill test." This is because floor coverings meeting the pill test will not spread flame significantly until a room fire approaches flashover. At flashover, the spread of flame across a floor covering will have minimal impact on the already existing hazard. The minimum critical radiant flux of a floor covering that will pass the FF 1-70 test has been determined to be approximately 0.04 W/cm^2 (Tu, King-Mon and Davis, Sanford, "Flame Spread of Carpet Systems Involved in Room Fires," NFSIR 76-1013, Center for Fire Research, National Bureau of Standards, June 1976). The flooring radiant panel is only able to determine critical radiant flux values to 0.1 W/cm^2. This provision will prevent use of a noncomplying material, which can create a problem, especially when the *Code* is used outside the United States where U.S. federal regulation FF 1-70 (16 CFR 1630) is not mandated.

A.10.2.7.1 Compliance with 16 CFR 1630, "Standard for the Surface Flammability of Carpets and Rugs" (FFI-70), is considered equivalent to compliance with ASTM D 2859, *Standard Test Method for Ignition Characteristic of Finished Textile Floor Covering Materials*.

A.10.2.7.2 The fire performance of some floor finishes has been tested, and traditional finish floors and floor coverings, such as wood flooring and resilient floor coverings, have not proved to present an unusual hazard.

A.10.2.7.3 ASTM E 648, *Standard Test Method for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*, and NFPA 253, *Standard Method of Test for Critical Radiant Flux of Floor Covering Systems Using a Radiant Heat Energy Source*, are considered nationally recognized consensus standard test methods for determining the critical radiant flux from floor covering systems and are likely to yield equivalent test results.

A.10.3.1 Testing per NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*, applies to textiles and films used in a hanging configuration. If the textiles are to be applied to surfaces of buildings or backing materials as interior finishes for use in buildings, they should be treated as interior wall and ceiling finishes in accordance with Section 10.2 of this *Code*, and they should then be tested for flame spread index and smoke developed index values in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*, or for flame spread and flashover in accordance with NFPA 265, *Standard Methods of Fire Tests for Evaluating Room Fire Growth Contribution of Textile or Expanded Vinyl Wall Coverings on Full Height Panels and Walls*. Films and other materials used as interior finish applied to surfaces of buildings should be tested for flame spread index and smoke developed index values in accordance with ASTM E 84 or ANSI/UL 723 or for heat and smoke release and flashover in accordance with NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth*.

The test results from NFPA 701 are suitable for classification purposes but should not be used as input into fire models, because they are not generated in units suitable for engineering calculations.

A.10.3.2.1 The Class I requirement associated with testing in accordance with NFPA 260, *Standard Methods of Tests and Classification System for Cigarette Ignition Resistance of Components of Upholstered Furniture*, and the char length of not more than 1½ in. (38 mm) required with testing in accordance with NFPA 261, *Standard Method of Test for Determining Resistance of Mock-Up Upholstered Furniture Material Assemblies to Ignition by Smoldering Cigarettes*, are indicators that the furniture item or mattress is resistant to a cigarette ignition. A fire that smolders for an excessive period of time without flaming can reduce the tenability within the room or area of fire origin without developing the temperatures necessary to operate automatic sprinklers.

The test results from NFPA 260 and from NFPA 261 are suitable for classification purposes but should not be used as input into fire models because they are not generated in units suitable for engineering calculations.

Until recently, NFPA 260 was equivalent to ASTM E 1353, *Standard Test Methods for Cigarette Ignition Resistance of Components of Upholstered Furniture*, and NFPA 261 was equivalent to ASTM E 1352, *Standard Test Method for Cigarette Ignition Resistance of Mock-Up Upholstered Furniture Assemblies*. However, that changed when NFPA 260 and NFPA 261 adopted the new NIST standard reference material (SRM 1196) as the igniting cigarette and ASTM E 1352 and ASTM E 1353 did not, meaning that ASTM E 1352 and ASTM E 1353 use commercial cigarettes that are low-ignition propensity and have a low likelihood of properly assessing smoldering potential.

A.10.3.2.2 The char length of not more than 2 in. (51 mm) required in 16 CFR 1632, "Standard for the Flammability of Mattresses and Mattress Pads" (FF 4-72), is an indicator that the mattress is resistant to a cigarette ignition. United States federal regulations require mattresses in this country to comply with 16 CFR 1632.

A.10.3.3 The intent of the provisions of 10.3.3 is as follows:

(1) The peak heat release rate of not more than 80 kW by a single upholstered furniture item was chosen based on maintaining a tenable environment within the room of fire origin, and the sprinkler exception was developed because the sprinkler system helps to maintain tenable conditions, even if the single upholstered furniture item were to have a peak rate of heat release in excess of 80 kW.
(2) The total heat release of not more than 25 MJ by the single upholstered furniture item during the first 10 minutes of the test was established as an additional safeguard to protect against the adverse conditions that would be created by an upholstered furniture item that released its heat in other than the usual measured scenario, and the following should also be noted:
   (a) During the test for measurement of rate of heat release, the instantaneous heat release value usually peaks quickly and then quickly falls off, so as to create a triangle-shaped curve.
   (b) In the atypical case, if the heat release were to peak and remain steady at that elevated level, as opposed to quickly falling off, the 80 kW limit would not ensure safety.
   (c) Only a sprinkler exception is permitted in lieu of the test because of the ability of the sprinkler system to control the fire.

Actual test results for heat, smoke, and combustion product release from ASTM E 1537, *Standard Test Method for Fire Testing of Upholstered Furniture*, might be suitable for use as input into fire models for performance-based design. Furthermore, California Technical Bulletin 133, "Flammability Test Procedure for Seating Furniture for Use in Public Occupancies," includes pass/fail criteria for a single upholstered furniture item of 80 kW peak heat release rate and 25 MJ total heat release over the first 10 minutes of the test.

A.10.3.4 The intent of the provisions of 10.3.4 is as follows:

(1) The peak heat release rate of not more than 100 kW by a single mattress was chosen based on maintaining a tenable environment within the room of fire origin, and the sprinkler exception was developed because the sprinkler system helps to maintain tenable conditions, even if the single mattress were to have a peak rate of heat release in excess of 100 kW.
(2) The total heat release of not more than 25 MJ by the single mattress during the first 10 minutes of the test was established as an additional safeguard to protect against the adverse conditions that would be created by a mattress that released its heat in other than the usual measured scenario, and the following should also be noted:
   (a) During the test for measurement of rate of heat release, the instantaneous heat release value usually peaks quickly and then quickly falls off, so as to create a triangle-shaped curve.
   (b) In the atypical case, if the heat release were to peak and remain steady at that elevated level, as opposed to quickly falling off, the 100 kW limit would not ensure safety.
   (c) Only a sprinkler exception is permitted in lieu of the test because of the ability of the sprinkler system to control the fire.

Actual test results for heat, smoke, and combustion product release from ASTM E 1590, *Standard Test Method for Fire Testing of Mattresses*, might be suitable for use as input into fire models for performance-based design. Furthermore, California Technical Bulletin 129, "Flammability Test Procedure for

Mattresses for Use in Public Buildings," includes pass/fail criteria for a single mattress of 100 kW peak heat release rate and 25 MJ total heat release over the first 10 minutes of test.

A.10.3.5 Christmas trees that are not effectively flame-retardant treated, ordinary crepe paper decorations, and pyroxylin plastic decorations might be classified as highly flammable.

A.10.3.7 Neither UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*, nor NFPA 289, *Standard Method of Fire Test for Individual Fuel Packages*, is intended for evaluating interior wall and ceiling finish materials. Actual test results for heat, smoke, and combustion product release from UL 1975 or from NFPA 289 might be suitable for use as input into fire models intended for performance-based design.

A.11.2.2 Escape chutes, controlled descent devices, and elevators are permitted to provide escape routes in special structures; however, they should not be substituted for the provisions of this *Code*.

A.11.2.2.4.1 The grade level of open structures, which by their very nature contain an infinite number of means of egress, are exempt from the requirements for number of means of egress.

A.11.3.1.3.1(2) The incidental accessory uses are intended to apply to small office spaces or lounge areas and similar uses that are used by tower employees.

A.11.3.2.4 The Washington Monument in Washington, DC, is an example of a tower where it would be impracticable to provide a second stairway.

A.11.3.4.2(2) The incidental accessory uses are intended to apply to small office spaces or lounge areas and similar uses that are used by tower employees.

A.11.3.4.4.6.2(2) Occupants of air traffic control towers might be required by administrative controls to remain in the facility when a fire occurs so they can perform orderly transfer of operations. Methods to limit compromising the means of egress might include a fire resistance–rated separation between discharge paths or smoke control in large spaces.

A.11.5 For further information on pier fire protection, see NFPA 307, *Standard for the Construction and Fire Protection of Marine Terminals, Piers, and Wharves*.

A.11.6 Fire safety information for manufactured home parks is found in NFPA 501A, *Standard for Fire Safety Criteria for Manufactured Home Installations, Sites, and Communities*.

A.11.7.3.2 It is not the intent that emergency access openings be readily openable from the exterior by the public but that they be easily opened with normal fire department equipment.

A.11.8.3.1 Where an occupancy chapter (Chapters 12 through 42) permits the omission of sprinklers in specific spaces, such as small bathrooms and closets in residential occupancies, the building is still considered to be protected throughout for the purposes of 11.8.3.1.

A.11.8.4.1 The need for voice communication can be based on a decision regarding staged or partial evacuation versus total evacuation of all floors. The determination of need is a function of occupancy classification and building height.

A.11.8.6 It is not the intent of the paragraph to require any of the equipment in the list, other than the telephone for fire department use, but only to provide the controls, panels, annunciators, and similar equipment at this location if the equipment is provided or required by another section of the *Code*.

A.11.8.8.1 With video systems, such as standard CCTV security systems typically installed in high-rise buildings, real-time images of occupants' and emergency responders' presence and movement (or lack thereof) in exits, especially at multiple locations of the same exit stairway, can provide critical information about current and developing conditions that should be taken into account in emergency management in accordance with the building's Emergency Action Plan.

Having video cameras positioned to capture images of an exit stairway, including just prior to the discharge doorway from the exit, provides information on the number and flow (in persons per minute, for example) of the occupants, among other information, including access by responding fire fighters using stairs if elevators are not available. It is not essential that the camera views and image resolution be sufficient to identify specific individuals. Depending on the context (including security applications), such specific-person identification might be essential, desirable, undesirable or forbidden. For post-incident evaluation and analysis of egress performance, it is helpful to have image quality and camera angle such that the lateral and front-to-back positions of individuals, relative to the stair width, are clear.

For example, a high-rise building could have cameras at the ground level (assuming this is the level of exit discharge) and at every fifth floor above, and perhaps below grade, for each of the exit stairs. As well as providing a reasonable sampling of evacuee presence and movement within the exit stair system (information important for real-time situation awareness), a comparison of times at which particular individuals pass different cameras provides important data on evacuation movement speed and (indirectly) average occupant density, in addition to flow and number of evacuees overall.

When designing and installing a video monitoring system, and in conjunction with the authority having jurisdiction, the following items should be considered in the operation of the system:

(1) Inspection, testing, and maintenance of equipment
(2) Duration/hours of operation
(3) Storage and retention of information
(4) Activation of the system
(5) Integration with the building's emergency action plan

A.11.9.3.3.1 The requirements of this paragraph can be considered as a Class 4, Type 60, system per NFPA 110, *Standard for Emergency and Standby Power Systems*.

A.12.1.2 Assembly occupancy requirements should be determined on a room-by-room basis, a floor-by-floor basis, and a total building basis. The requirements for each room should be based on the occupant load of that room, and the requirements for each floor should be based on the occupant load of that floor, but the requirements for the assembly building overall should be based on the total occupant load. Therefore, it is quite feasible to have several assembly occupancies with occupant loads of 300 or less grouped together in a single building. Such a building would be an assembly occupancy with an occupant load of over 1000.

A.12.1.3.3 For example, an assembly room for the residents of a detention occupancy will not normally be subject to simultaneous occupancy.

A.12.1.4.2 An understanding of the term *accessory room* might be useful to the enforcer of the *Code*, although the term is not used within the *Code*. An accessory room includes a dressing room, the property master's work and storage rooms, the carpenter's room, or similar rooms necessary for legitimate stage operations.

A.12.1.7.1 The increase in occupant load above that calculated using occupant load factors from Table 7.3.1.2 is permitted if the provisions of 12.1.7.1 are followed. The owner or operator has the right to submit plans and to be permitted an increase in occupant load if the plans comply with the *Code*. The authority having jurisdiction is permitted to reject the plan for increase in occupant load if the plan is unrealistic, inaccurate, or otherwise does not properly reflect compliance with other *Code* requirements. It is not the intent of the provisions of 12.1.7.1 to prohibit an increase in occupant load solely on the basis of exceeding the limits calculated using occupant load factors from Table 7.3.1.2.

To assist in preventing serious overcrowding incidents in sports arenas, stadia, and similar occupancies, spectator standing room should not be permitted between the seating areas and the playing areas, except in horse race and dog track facilities.

Where a capacity or near-capacity audience is anticipated, all seating should be assigned with tickets showing the section, row, and seat number.

Where standing room is permitted, the capacity of the standing area should meet the following criteria:

(1) The capacity should be determined on the basis of 5 ft^2 (0.46 m^2) per person.
(2) The capacity should be added to the seating capacity in determining egress requirements.
(3) The capacity should be located to the rear of the seating area.
(4) The capacity should be assigned standing-room-only tickets according to the area designated for the purpose.

The number of tickets sold, or otherwise distributed, should not exceed the aggregate number of seats plus the approved standing room numbers.

A.12.2.2.3.1(1) The seating plan and the means of egress should be reviewed each time the seating is substantially rearranged.

A.12.2.3.2 The provisions of 12.2.3.2 should be applied within the audience seating chamber and to the room doors. The capacity of means of egress components encountered after leaving the audience seating chamber, such as concourses, lobbies, exit stair enclosures, and the exit discharge, should be calculated in accordance with Section 7.3.

A.12.2.3.6.6 The original *Code* wording exempted sports arenas and railway stations. If an assembly occupancy was not similar to a sports arena or railway station, it was often judged ineligible to use the provision of 12.2.3.6.6. A list of exempted assembly venues also raises the question of why other occupancies are not included and necessitates additions to the list. For example, an exhibit hall of very large size might have several main entrances/exits. A theater extending the width of a block cannot really have a main entrance/exit in one confined location. A restaurant might have a main entrance serving the parking lot and another main entrance for those entering from the street. The authority having jurisdiction needs to determine where such arrangements are acceptable.

A.12.2.4 It is not the intent to require four means of egress from each level of an assembly occupancy building having a total occupant load of more than 1000 where, individually, the floors have occupant loads of less than 1000.

A.12.2.5.4.2 This requirement and the associated requirement of 12.2.5.4.3 have the effect of prohibiting festival seating, unless it truly is a form of seating, such as lawn seating, where generous spaces are commonly maintained between individuals and small groups so that people can circulate freely at any time. Such lawn seating is characterized by densities of about one person per 15 ft^2 (1.4 m^2). Both requirements prohibit uncontrolled crowd situations, such as in front of stages at rock music concerts where the number and density of people is uncontrolled by architectural or management features.

A.12.2.5.4.3 This requirement is intended to facilitate rapid emergency access to individuals who are experiencing a medical emergency, especially in the case of cardiopulmonary difficulties, where there is a need for rapid medical attention from trained personnel. The requirement also addresses the need for security and law enforcement personnel to reach individuals whose behavior is endangering themselves and others.

A.12.2.5.4.4 The catchment area served by an aisle accessway or aisle is the portion of the total space that is naturally served by the aisle accessway or aisle. Hence, the requirement for combining the required capacity where paths converge is, in effect, a restatement of the idea of a catchment area. The establishment of catchment areas should be based on a balanced use of all means of egress, with the number of persons in proportion to egress capacity.

A.12.2.5.5 For purposes of the means of egress requirements of this *Code*, tablet-arm chair seating is not considered seating at tables. Dinner theater–style configurations are required to comply with the aisle accessway provisions applying to seating at tables and the aisle requirements of 12.2.5.6, if the aisles contain steps or are ramped. *(See also 7.1.7 and A.7.1.7.2.)*

A.12.2.5.5.1 Seats having reclining backs are assumed to be in their most upright position when unoccupied.

A.12.2.5.5.5 The system known as *continental seating* has one pair of egress doors provided for every five rows that is located close to the ends of the rows. In previous editions of the *Code*, such egress doors were required to provide a clear width of not less than 66 in. (1675 mm) discharging into a foyer, into a lobby, or to the exterior of the building. This continental seating arrangement can result in egress flow times (i.e., with nominal flow times of approximately 100 seconds, rather than 200 seconds) that are approximately one-half as long as those resulting where side aisles lead to more remote doors. Such superior egress flow time performance is desirable in some situations; however, special attention should be given either to a comparably good egress capacity for other parts of the egress system or to sufficient space to accommodate queuing outside the seating space.

A.12.2.5.6.3 It is the intent to permit handrails to project not more than 3½ in. (90 mm) into the clear width of aisles required by 12.2.5.6.3.

A.12.2.5.6.4.1 Technical information about the convenience and safety of ramps and stairs having gradients in the region of 1 in 8 clearly suggests that the goal should be slopes for ramps that are less steep and combinations of stair risers and treads that are, for example, superior to 4 in. (100 mm) risers and 32 in. (865 mm) treads. This goal should be kept in mind by designers in establishing the gradient of seating areas to be served by aisles.

A.12.2.5.6.5(3) Tread depth is more important to stair safety than is riser height. Therefore, in cases where the seating area gradient is less than 5 in 11, it is recommended that the tread dimension be increased beyond 11 in. (280 mm), rather than reducing the riser height. Where the seating area gradient exceeds 8 in 11, it is recommended that the riser height be increased while maintaining a tread depth of not less than 11 in. (280 mm).

A.12.2.5.6.9 Failure to provide a handrail within a 30 in. (760 mm) horizontal distance of all required portions of the aisle stair width means that the egress capacity calculation is required to be modified as specified by 12.2.3.3(3). This modification might lead to an increase in the aisle width. Although this increase will compensate for reduced egress efficiency, it does not help individuals walking on such portions of stairs to recover from missteps, other than by possibly marginally reducing the crowding that might exacerbate the problem of falls. *(See also 7.2.2.4.)*

A.12.2.5.6.10 Certain tread cover materials such as plush carpets, which are often used in theaters, produce an inherently well-marked tread nosing under most lighting conditions. On the other hand, concrete treads have nosings with a sharp edge and, especially under outdoor lighting conditions, are difficult to discriminate. Therefore, concrete treads require an applied marking stripe. The slip resistance of such marking stripes should be similar to the rest of the treads, and no tripping hazard should be created; luminescent, self-luminous, and electroluminescent tread markings have the advantage of being apparent in reduced light or in the absence of light.

A.12.2.5.7 For purposes of the means of egress requirements of this *Code*, seating at counters or at other furnishings is considered to be the same as seating at tables.

A.12.2.5.7.2 Effectively, where the aisle accessway is bounded by movable seating, the 12 in. (305 mm) minimum width might be increased by about 15 in. to 30 in. (380 mm to 760 mm) as seating is pushed in toward tables. Moreover, it is such movement of chairs during normal and emergency egress situations that makes the zero-clearance allowance workable. The allowance also applies to booth seating where people sitting closest to the aisle normally move out ahead of people farthest from the aisle.

A.12.2.5.7.3 See A.12.2.5.8.3.

A.12.2.5.7.4 The minimum width requirement as a function of accessway length is as follows:

(1) 0 in. (0 mm) for the first 6 ft (1830 mm) of length toward the exit
(2) 12 in. (305 mm) for the next 6 ft (1830 mm); that is, up to 12 ft (3660 mm) of length
(3) 12 in. to 24 in. (305 mm to 610 mm) for lengths from 12 ft to 36 ft (3.7 m to 11 m), the maximum length to the closest aisle or egress doorway permitted by 12.2.5.7.5

Any additional width needed for seating is to be added to these widths, as described in 12.2.5.8.3.

A.12.2.5.8.1 See 7.1.7 and A.7.1.7.2 for special circulation safety precautions applicable where small elevation differences occur.

A.12.2.5.8.2 It is important to make facilities accessible to people using wheelchairs. See ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities,* which provides guidance on appropriate aisle widths.

A.12.2.5.8.3 Figure A.12.2.5.8.3 shows typical measurements involving seating and tables abutting an aisle. For purposes of the means of egress requirements of this *Code*, seating at counters or other furnishings is considered to be the same as seating at tables.

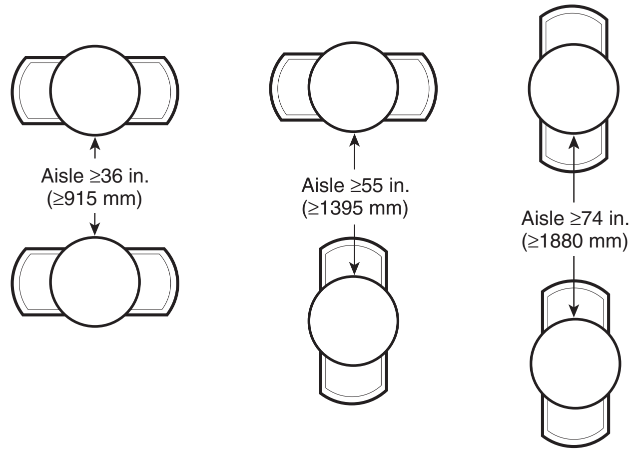

FIGURE A.12.2.5.8.3 Seating at Tables Abutting an Aisle.

A.12.2.11.1.1 This requirement includes provisions of guards and rails at the front of boxes, galleries, and balconies, and at aisle accessways adjacent to vomitories and orchestra pits.

A.12.2.11.1.6.2 The written plan should identify the unguarded areas and should include precautions and provisions to mitigate the fall hazard. Such precautions and provisions might include the following:

(1) Training
(2) Choreography
(3) Blocking
(4) Rehearsal
(5) Restricted access to the stage
(6) Restricted access to unguarded edges
(7) Warning lights
(8) Audible warnings
(9) Tactile edges
(10) Warning barriers
(11) Signage
(12) Temporary barriers
(13) Personal fall protection
(14) Fall restraint
(15) Spotters

A.12.3.1(1) The allowance for unenclosed stairs or ramps presumes the balcony or mezzanine complies with the other provisions of the *Code,* such as travel distance to exits in accordance with 12.2.6 and number of exits in accordance with 12.2.4. For the purposes of this exception, a balcony with glazing that provides a visual awareness of the main assembly area is considered open.

A.12.3.4.2.3 The intent is to require detectors only in nonsprinklered hazardous areas that are unoccupied. When the building is occupied, the detectors in the unoccupied, unsprinklered hazardous areas will initiate occupant notification. If the building is unoccupied, the fire in the nonsprinklered hazardous area is not a life safety issue, and the detectors, upon activation, are not required to notify anyone.

The signal from a detector is permitted to be sent to a control panel in an area that is occupied when the building is occupied, but that is unoccupied when the building is unoccupied, without the need for central station monitoring or the equivalent.

A.12.3.4.3.5 Examples of devices that might be used to provide alternative visible means include scoreboards, message boards, and other electronic devices.

A.12.3.5.3(1) It is the intent to permit a single multipurpose room of less than 12,000 ft^2 (1115 m^2) to have certain small rooms as part of the single room. These rooms could be a kitchen, an office, an equipment room, and the like. It is also the intent that an addition could be made to an existing building, without requiring that the existing building be sprinklered, where both the new and existing buildings have independent means of egress and a fire-rated separation is provided to isolate one building from the other.

A school gymnasium with egress independent of, and separated from, the school would be included in this exception, as would a function hall attached to a church with a similar egress arrangement.

A.12.3.5.3(3) Examples of low fire hazard uses include spectator sporting events, concerts, and performances on platforms.

The following uses are not low fire hazard uses: concerts and performances on stages; tradeshows; exhibitions and display of combustible items; displays of vehicles, boats, or similar items; or events using open flames or pyrotechnic effects.

A.12.4.1.1 Life safety evaluations are examples of performance-based approaches to life safety. In this respect, significant guidance in the form and process of life safety evaluations is provided by Chapter 5, keeping in mind the fire safety emphasis in Chapter 5. Performance criteria, scenarios, evaluation, safety factors, documentation, maintenance, and periodic assessment (including a warrant of fitness) all apply to the broader considerations in a life safety evaluation. A life safety evaluation deals not only with fire but also with storms, collapse, crowd behavior, and other related safety considerations for which a checklist is provided in A.12.4.1.3. Chapter 5 provides guidance, based on fire safety requirements, for establishing a documented case showing that products of combustion in all conceivable fire scenarios will not significantly endanger occupants using means of egress in the facility (e.g., due to fire detection, automatic suppression, smoke control, large-volume space, or management procedures). Moreover, means of egress facilities plus facility management capabilities should be adequate to cope with scenarios where certain egress routes are blocked for some reason.

In addition to making realistic assumptions about the capabilities of persons in the facility (e.g., an assembled crowd including many disabled persons or persons unfamiliar with the facility), the life safety evaluation should include a factor of safety of not less than 2.0 in all calculations relating to hazard development time and required egress time (the combination of flow time and other time needed to detect and assess an emergency condition, initiate egress, and move along the egress routes). The factor of safety takes into account the possibility that half of the egress routes might not be used (or be usable) in certain situations.

Regarding crowd behavior, the potential hazards created by larger masses of people and greater crowd densities (which can be problematic during ingress, occupancy, and egress) demand that technology be used by designers, managers, and authorities responsible for buildings to compensate for the relaxed egress capacity provisions of Table 12.4.2.3. In very large buildings for assembly use, the hazard of crowd crushes can exceed that of fire or structural failure. Therefore, the building designers, managers, event planners, security personnel, police authorities, and fire authorities, as well as the building construction authorities, should understand the potential problems and solutions, including coordination of their activities. For crowd behavior, this understanding includes factors of space, energy, time, and information, as well as specific crowd management techniques, such as metering. Published guidance on these factors and techniques is found in the *SFPE Handbook of Fire Protection Engineering*, Section 3, Chapter 13, pp. 3-342–3-366 (Proulx, G., "Movement of People"), and the publications referenced therein.

Table 12.2.3.2 and Table 12.4.2.3 are based on a linear relationship between number of seats and nominal flow time, with not less than 200 seconds (3.3 minutes) for 2000 seats plus 1 second for every additional 50 seats up to 25,000. Beyond 25,000 total seats, the nominal flow time is limited to 660 seconds (11 minutes). Nominal flow time refers to the flow time for the most able group of patrons; some groups less familiar with the premises or less able groups might take longer to pass a point in the egress system. Although three or more digits are noted in the tables, the resulting calculations should be assumed to provide only two significant figures of precision.

A.12.4.1.3 Factors to be considered in a life safety evaluation include the following:

(1) Nature of the events being accommodated, including the following:
   (a) Ingress, intra-event movement, and egress patterns
   (b) Ticketing and seating policies/practices
   (c) Event purpose (e.g., sports contest, religious meeting)
   (d) Emotional qualities (e.g., competitiveness) of event
   (e) Time of day when event is held
   (f) Time duration of single event
   (g) Time duration of attendees' occupancy of the building
(2) Occupant characteristics and behavior, including the following:
   (a) Homogeneity
   (b) Cohesiveness
   (c) Familiarity with building
   (d) Familiarity with similar events
   (e) Capability (as influenced by factors such as age, physical abilities)
   (f) Socioeconomic factors
   (g) Small minority involved with recreational violence
   (h) Emotional involvement with the event and other occupants
   (i) Use of alcohol or drugs
   (j) Food consumption
   (k) Washroom utilization
(3) Management, including the following:
   (a) Clear, contractual arrangements for facility operation/use as follows:
      i. Between facility owner and operator
      ii. Between facility operator and event promoter
      iii. Between event promoter and performer
      iv. Between event promoter and attendee
      v. With police forces
      vi. With private security services
      vii. With ushering services

(b) Experience with the building
(c) Experience with similar events and attendees
(d) Thorough, up-to-date operations manual
(e) Training of personnel
(f) Supervision of personnel
(g) Communications systems and utilization
(h) Ratios of management and other personnel to attendees
(i) Location/distribution of personnel
(j) Central command location
(k) Rapport between personnel and attendees
(l) Personnel support of attendee goals
(m) Respect of attendees for personnel due to the following:
i. Dress (uniform) standards
ii. Age and perceived experience
iii. Personnel behavior, including interaction
iv. Distinction between crowd management and control
v. Management concern for facility quality (e.g., cleanliness)
vi. Management concern for entire event experience of attendees (i.e., not just during occupancy of the building)

(4) Emergency management preparedness, including the following:
(a) Complete range of emergencies addressed in operations manual
(b) Power loss
(c) Fire
(d) Severe weather
(e) Earthquake
(f) Crowd incident
(g) Terrorism
(h) Hazardous materials
(i) Transportation accident (e.g., road, rail, air)
(j) Communications systems available
(k) Personnel and emergency forces ready to respond
(l) Attendees clearly informed of situation and proper behavior

(5) Building systems, including the following:
(a) Structural soundness
(b) Normal static loads
(c) Abnormal static loads (e.g., crowds, precipitation)
(d) Dynamic loads (e.g., crowd sway, impact, explosion, wind, earthquake)
(e) Stability of nonstructural components (e.g., lighting)
(f) Stability of movable (e.g., telescoping) structures
(g) Fire protection
(h) Fire prevention (e.g., maintenance, contents, housekeeping)
(i) Compartmentation
(j) Automatic detection and suppression of fire
(k) Smoke control
(l) Alarm and communications systems
(m) Fire department access routes and response capability
(n) Structural integrity
(o) Weather protection
(p) Wind
(q) Precipitation (attendees rush for shelter or hold up egress of others)
(r) Lightning protection
(s) Circulation systems
(t) Flowline or network analysis
(u) Waywinding and orientation
(v) Merging of paths (e.g., precedence behavior)
(w) Decision/branching points
(x) Route redundancies
(y) Counterflow, crossflow, and queuing situations
(z) Control possibilities, including metering
(aa) Flow capacity adequacy
(bb) System balance
(cc) Movement time performance
(dd) Flow times
(ee) Travel times
(ff) Queuing times
(gg) Route quality
(hh) Walking surfaces (e.g., traction, discontinuities)
(ii) Appropriate widths and boundary conditions
(jj) Handrails, guardrails, and other rails
(kk) Ramp slopes
(ll) Step geometries
(mm) Perceptual aspects (e.g., orientation, signage, marking, lighting, glare, distractions)
(nn) Route choices, especially for vertical travel
(oo) Resting/waiting areas
(pp) Levels of service (overall crowd movement quality)
(qq) Services
(rr) Washroom provision and distribution
(ss) Concessions
(tt) First aid and EMS facilities
(uu) General attendee services

A scenario-based approach to performance-based fire safety is addressed in Chapter 5. In addition to using such scenarios and, more generally, the attention to performance criteria, evaluation, safety factors, documentation, maintenance, and periodic assessment required when the Chapter 5 option is used, life safety evaluations should consider scenarios based on characteristics important in assembly occupancies. These characteristics include the following:

(1) Whether there is a local or mass awareness of an incident, event, or condition that might provoke egress
(2) Whether the incident, event, or condition stays localized or spreads
(3) Whether or not egress is desired by facility occupants
(4) Whether there is a localized start to any egress or mass start to egress
(5) Whether exits are available or not available

Examples of scenarios and sets of characteristics that might occur in a facility follow.

Scenario 1. Characteristics: mass start, egress desired (by management and attendees), exits not available, local awareness.

Normal egress at the end of an event occurs just as a severe weather condition induces evacuees at the exterior doors to retard or stop their egress. The backup that occurs in the egress system is not known to most evacuees, who continue to press forward, potentially resulting in a crowd crush.

Scenario 2. Characteristics: mass start, egress not desired (by management), exits possibly not available, mass awareness.

An earthquake occurs during an event. The attendees are relatively safe in the seating area. The means of egress outside the seating area are relatively unsafe and vulnerable to aftershock damage. Facility management discourages mass egress until the means of egress can be checked and cleared for use.

Scenario 3. Characteristics: local start, incident stays local, egress desired (by attendees and management), exits available, mass awareness.

A localized civil disturbance (e.g., firearms violence) provokes localized egress, which is seen by attendees, generally, who then decide to leave also.

Scenario 4. Characteristics: mass start, egress desired (by attendees), incident spreads, exits not available, mass awareness.

In an open-air facility unprotected from wind, precipitation, and lightning, sudden severe weather prompts egress to shelter, but not from the facility. The means of egress congest and block quickly as people in front stop once they are under shelter, while people behind them continue to press forward, potentially resulting in a crowd crush.

These scenarios illustrate some of the broader factors to be taken into account when assessing the capability of both building systems and management features on which reliance is placed in a range of situations, not just fire emergencies. Some scenarios also illustrate the conflicting motivations of management and attendees, based on differing perceptions of danger and differing knowledge of hazards, countermeasures, and capabilities. Mass egress might not be the most appropriate life safety strategy in some scenarios, such as Scenario 2.

Table A.12.4.1.3 summarizes the characteristics in the scenarios and provides a framework for developing other characteristics and scenarios that might be important for a particular facility, hazard, occupant type, event, or management.

A.12.4.2 Outdoor facilities are not accepted as inherently smoke-protected but must meet the requirements of smoke-protected assembly seating in order to utilize the special requirements for means of egress.

A.12.4.6.12 Prior editions of the *Code* required stages to be protected by a Class III standpipe system in accordance with NFPA 14, *Standard for the Installation of Standpipe and Hose Systems.* NFPA 14 requires that Class II and Class III standpipes be automatic — not manual — because they are intended to be used by building occupants. Automatic standpipe systems are required to provide not less than 500 gpm (1890 L/min) at 100 psi (689 kN/m^2). This requirement often can be met only if a fire pump is installed. Installation of a fire pump presents an unreasonable burden for the system supplying the two hose outlets at the side of the stage. The revised wording of 12.4.6.12 offers some relief by permitting the hose outlets to be in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems.*

A.12.4.8 Where a special amusement building is installed inside another building, such as within an exhibit hall, the special amusement building requirements apply only to the special amusement building. For example, the smoke detectors required by 12.4.8.4 are not required to be connected to the building's system. Where installed in an exhibit hall, such smoke detectors are also required to comply with the provisions applicable to an exhibit.

A.12.4.8.1 The aggregate horizontal projections of a multilevel play structure are indicative of the number of children who might be within the structure and at risk from a fire or similar emergency. The word "aggregate" is used in recognition of the fact that the platforms and tubes that make up the multilevel play structure run above each other at various levels. In calculating the area of the projections, it is important to account for all areas that might be expected to be occupied within, on top of, or beneath the components of the structure when the structure is used for its intended function.

A.12.4.8.2 See A.12.4.8.1.

A.12.4.8.7.3 Consideration should be given to the provision of directional exit marking on or adjacent to the floor.

A.12.4.11.2(2) Delayed-egress locks on doors from the airport loading walkway into the airport terminal building might compromise life safety due to the limited period of time the airport loading walkway will provide protection for emergency egress. The requirement of 12.4.11.2(2) would not limit the use of access-controlled or delayed-egress hardware from the airport terminal building into the airport loading walkway.

A.12.7.3(3)(a) Securely supported altar candles in churches that are well separated from any combustible material are permitted. On the other hand, lighted candles carried by children wearing cotton robes present a hazard too great to be permitted. There are many other situations of intermediate hazard where the authority having jurisdiction will have to exercise judgment.

A.12.7.4.1 Fabric applied over unused seating sections should meet the requirements of 12.7.4.

A.12.7.4.3 The phrase "unprotected materials containing foamed plastic" is meant to include foamed plastic items covered by "thermally thin" combustible fabrics or paint. *(See A.10.2.3.4.)*

A.12.7.5.3.7.1(3) See A.12.4.1.1.

A.12.7.6.2 Crowd managers and crowd manager supervisors need to clearly understand the required duties and responsibilities specific to the venue's emergency plan. The crowd management training program should include a clear appreciation of crowd dynamics factors including space, energy, time, and information, as well as specific crowd management techniques, such as metering. Training should involve specific actions necessary during normal and emergency operations, and include an assessment of people-handling capabilities of a space prior to its use, the identification of hazards, an evaluation of projected levels of occupancy, the adequacy of means of ingress and egress and identification of ingress and egress barriers, the processing procedures such as ticket collection, and the expected types of human behavior. Training should

Table A.12.4.1.3 Life Safety Evaluation Scenario Characteristics Matrix

					Management		Occupants						
Scenario	Local Awareness	Mass Awareness	Incident Localized	Incident Spreads	Egress Desired	Egress Not Desired	Egress Desired	Egress Not Desired	Local Start	Mass Start	Exits Available	Exits Not Available	Other
1	X	—	—	—	X	—	X	—	—	X	—	X	—
2	—	X	—	—	—	X	—	—	—	X	—	X	—
3	—	X	X	—	X	—	X	—	X	—	X	—	—
4	—	X	—	X	—	—	X	—	—	X	—	X	—

also involve the different types of emergency evacuations and, where required by the emergency plan, relocation and shelter-in-place operations, and the challenges associated with each.

A.12.7.6.4 In large facilities, crowd managers typically have a specific area of responsibility. In such facilities, the requirements of 12.7.6.4 might apply only to the crowd managers' area of responsibility.

A.12.7.7 It is important that an adequate number of competent attendants is on duty at all times when the assembly occupancy is occupied.

A.12.7.7.3 It is not the intent of this provision to require an announcement in bowling alleys, cocktail lounges, restaurants, or places of worship.

A.13.1.2 Assembly occupancy requirements should be determined on a room-by-room basis, a floor-by-floor basis, and a total building basis. The requirements for each room should be based on the occupant load of that room, and the requirements for each floor should be based on the occupant load of that floor, but the requirements for the assembly building overall should be based on the total occupant load. Therefore, it is quite feasible to have several assembly occupancies with occupant loads of 300 or less grouped together in a single building. Such a building would be an assembly occupancy with an occupant load of over 1000.

A.13.1.3.3 For example, an assembly room for the residents of a detention occupancy will not normally be subject to simultaneous occupancy.

A.13.1.4.2 An understanding of the term *accessory room* might be useful to the enforcer of the *Code*, although the term is not used within the *Code*. An accessory room includes a dressing room, the property master's work and storage rooms, the carpenter's room, or similar rooms necessary for legitimate stage operations.

A.13.1.7.1 The increase in occupant load above that calculated using occupant load factors from Table 7.3.1.2 is permitted if the provisions of 13.1.7.1 are followed. The owner or operator has the right to submit plans and to be permitted an increase in occupant load if the plans comply with the *Code*. The authority having jurisdiction is permitted to reject the plan for increase in occupant load if the plan is unrealistic, inaccurate, or otherwise does not properly reflect compliance with other *Code* requirements. It is not the intent of the provisions of 13.1.7.1 to prohibit an increase in occupant load solely on the basis of exceeding the limits calculated using occupant load factors from Table 7.3.1.2.

Existing auditorium and arena structures might not be designed for the added occupant load beyond the fixed seating. The authority having jurisdiction should consider exit access and aisles before permitting additional occupant load in areas using seating such as festival seating or movable seating on the auditorium or arena floor area.

To assist in preventing serious overcrowding incidents in sports arenas, stadia, and similar occupancies, spectator standing room should not be permitted between the seating areas and the playing areas, except in horse race and dog track facilities.

Where a capacity or near-capacity audience is anticipated, all seating should be assigned with tickets showing the section, row, and seat number.

Where standing room is permitted, the capacity of the standing area should meet the following criteria:

(1) The capacity should be determined on the basis of 5 ft^2 (0.46 m^2) per person.
(2) The capacity should be added to the seating capacity in determining egress requirements.
(3) The capacity should be located to the rear of the seating area.
(4) The capacity should be assigned standing-room-only tickets according to the area designated for the purpose.

The number of tickets sold, or otherwise distributed, should not exceed the aggregate number of seats plus the approved standing room numbers.

A.13.2.2.3.1(1) The seating plan and the means of egress should be reviewed each time the seating is substantially rearranged.

A.13.2.3.2 The provisions of 13.2.3.2 should be applied within the audience seating chamber and to the room doors. The capacity of means of egress components encountered after leaving the audience seating chamber, such as concourses, lobbies, exit stair enclosures, and the exit discharge, should be calculated in accordance with Section 7.3.

A.13.2.3.6.6 The original *Code* wording exempted sports arenas and railway stations. If an assembly occupancy was not similar to a sports arena or railway station, it was often judged ineligible to use the provision of 13.2.3.6.6. A list of exempted assembly venues also raises the question of why other occupancies are not included and necessitates additions to the list. For example, an exhibit hall of very large size might have several main entrances/exits. A theater extending the width of a block cannot really have a main entrance/exit in one confined location. A restaurant might have a main entrance serving the parking lot and another main entrance for those entering from the street. The authority having jurisdiction needs to determine where such arrangements are acceptable.

A.13.2.4 It is not the intent to require four means of egress from each level of an assembly occupancy building having a total occupant load of more than 1000 where, individually, the floors have occupant loads of less than 1000.

A.13.2.5.4.2 This requirement and the associated requirement of 13.2.5.4.3 have the effect of prohibiting festival seating, unless it truly is a form of seating, such as lawn seating, where generous spaces are commonly maintained between individuals and small groups so that people can circulate freely at any time. Such lawn seating is characterized by densities of about one person per 15 ft^2 (1.4 m^2). Both requirements prohibit uncontrolled crowd situations, such as in front of stages at rock music concerts where the number and density of people is uncontrolled by architectural or management features.

A.13.2.5.4.3 This requirement is intended to facilitate rapid emergency access to individuals who are experiencing a medical emergency, especially in the case of cardiopulmonary difficulties, where there is a need for rapid medical attention from trained personnel. The requirement also addresses the need for security and law enforcement personnel to reach individuals whose behavior is endangering themselves and others.

A.13.2.5.4.4 The catchment area served by an aisle accessway or aisle is the portion of the total space that is naturally served by the aisle accessway or aisle. Hence, the requirement for combining the required capacity where paths converge is, in effect, a restatement of the idea of a catchment area. The establishment of catchment areas should be based on a balanced use of all means of egress, with the number of persons in proportion to egress capacity.

A.13.2.5.5 For purposes of the means of egress requirements of this *Code*, tablet-arm chair seating is not considered seating at tables. Dinner theater–style configurations are required to comply with the aisle accessway provisions applying to seating at tables and the aisle requirements of 13.2.5.6, if the aisles contain steps or are ramped. *(See also 7.1.7 and A.7.1.7.2.)*

A.13.2.5.5.1 Seats having reclining backs are assumed to be in their most upright position when unoccupied.

A.13.2.5.5.5 The system known as *continental seating* has one pair of egress doors provided for every five rows that is located close to the ends of the rows. In previous editions of the *Code*, such egress doors were required to provide a clear width of not less than 66 in. (1675 mm) discharging into a foyer, into a lobby, or to the exterior of the building. This continental seating arrangement can result in egress flow times (i.e., with nominal flow times of approximately 100 seconds, rather than 200 seconds) that are approximately one-half as long as those resulting where side aisles lead to more remote doors. Such superior egress flow time performance is desirable in some situations; however, special attention should be given either to a comparably good egress capacity for other parts of the egress system or to sufficient space to accommodate queuing outside the seating space.

A.13.2.5.6.3 It is the intent to permit handrails to project not more than 3½ in. (90 mm) into the clear width of aisles required by 13.2.5.6.3.

A.13.2.5.6.4.1 Technical information about the convenience and safety of ramps and stairs having gradients in the region of 1 in 8 clearly suggests that the goal should be slopes for ramps that are less steep and combinations of stair risers and treads that are, for example, superior to 4 in. (100 mm) risers and 32 in. (865 mm) treads. This goal should be kept in mind by designers in establishing the gradient of seating areas to be served by aisles.

A.13.2.5.6.5(3) Tread depth is more important to stair safety than is riser height. Therefore, in cases where the seating area gradient is less than 5 in 11, it is recommended that the tread dimension be increased beyond 11 in. (280 mm), rather than reducing the riser height. Where the seating area gradient exceeds 8 in 11, it is recommended that the riser height be increased while maintaining a tread depth of not less than 11 in. (280 mm).

A.13.2.5.6.5(5) Completely uniform tread dimensions are preferred over aisle stair designs where tread depths alternate between relatively small intermediate treads between seating platforms and relatively large treads at seating platforms. A larger tread that is level with the seating platform is not needed to facilitate easy access to, and egress from, a row of seating. If this arrangement is used, it is important to provide a tread depth that is better than minimum for the intermediate tread; hence, 13 in. (330 mm) is specified. Where nonuniformities exist due to construction tolerance, they should not exceed 3⁄16 in. (4.8 mm) between adjacent treads.

A.13.2.5.6.9 Failure to provide a handrail within a 30 in. (760 mm) horizontal distance of all required portions of the aisle stair width means that the egress capacity calculation is required to be modified as specified by 13.2.3.3(3). This modification might lead to an increase in the aisle width. Although this increase will compensate for reduced egress efficiency, it does not help individuals walking on such portions of stairs to recover from missteps, other than by possibly marginally reducing the crowding that might exacerbate the problem of falls. *(See also 7.2.2.4.)*

A.13.2.5.6.10 Certain tread cover materials such as plush carpets, which are often used in theaters, produce an inherently well-marked tread nosing under most lighting conditions. On the other hand, concrete treads have nosings with a sharp edge and, especially under outdoor lighting conditions, are difficult to discriminate. Therefore, concrete treads require an applied marking stripe. The slip resistance of such marking stripes should be similar to the rest of the treads, and no tripping hazard should be created; luminescent, self-luminous, and electroluminescent tread markings have the advantage of being apparent in reduced light or in the absence of light.

A.13.2.5.7 For purposes of the means of egress requirements of this *Code*, seating at counters or at other furnishings is considered to be the same as seating at tables.

A.13.2.5.7.2 Effectively, where the aisle accessway is bounded by movable seating, the 12 in. (305 mm) minimum width might be increased by about 15 in. to 30 in. (380 mm to 760 mm) as seating is pushed in toward tables. Moreover, it is such movement of chairs during normal and emergency egress situations that makes the zero-clearance exception workable. The exception also applies to booth seating where people sitting closest to the aisle normally move out ahead of people farthest from the aisle.

A.13.2.5.7.3 See A.13.2.5.8.3.

A.13.2.5.7.4 The minimum width requirement as a function of accessway length is as follows:

(1) 0 in. (0 mm) for the first 6 ft (1830 mm) of length toward the exit
(2) 12 in. (305 mm) for the next 6 ft (1830 mm); that is, up to 12 ft (3660 mm) of length
(3) 12 in. to 24 in. (305 mm to 610 mm) for lengths from 12 ft to 36 ft (3.7 m to 11 m), the maximum length to the closest aisle or egress doorway permitted by 13.2.5.7.5

Any additional width needed for seating is to be added to these widths, as described in 13.2.5.8.3.

A.13.2.5.8.1 See 7.1.7 and A.7.1.7.2 for special circulation safety precautions applicable where small elevation differences occur.

A.13.2.5.8.2 It is important to make facilities accessible to people using wheelchairs. See ICC/ANSI A117.1, *American National Standard for Accessible and Usable Buildings and Facilities,* which provides guidance on appropriate aisle widths.

A.13.2.5.8.3 Figure A.13.2.5.8.3 shows typical measurements involving seating and tables abutting an aisle. Note that, for purposes of the means of egress requirements of this *Code*, seating at counters or other furnishings is considered to be the same as seating at tables.

A.13.3.1(1) The allowance for unenclosed stairs or ramps presumes the balcony or mezzanine complies with the other provisions of the *Code*, such as travel distance to exits in accordance with 13.2.6 and number of exits in accordance with 13.2.4. For the purposes of this exception, a balcony with glazing that provides a visual awareness of the main assembly area is considered open.

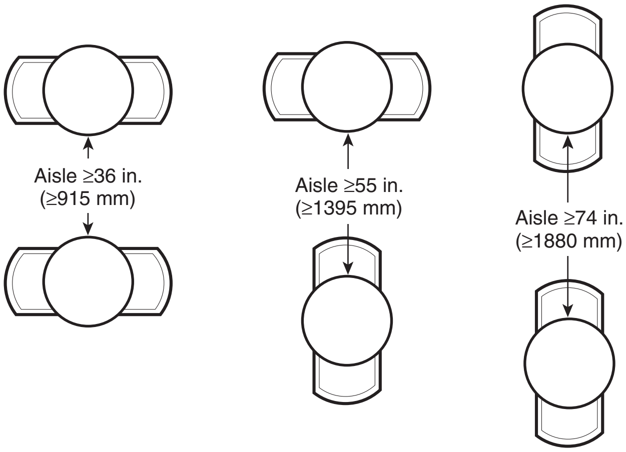

FIGURE A.13.2.5.8.3 Seating at Tables Abutting an Aisle.

A.13.3.4.2.3 The intent is to require detectors only in nonsprinklered hazardous areas that are unoccupied. Where the building is occupied, the detectors in the unoccupied, unsprinklered hazardous areas will initiate occupant notification. If the building is unoccupied, the fire in the nonsprinklered hazardous area is not a life safety issue, and the detectors, upon activation, are not required to notify anyone. The signal from a detector is permitted to be sent to a control panel in an area that is occupied when the building is occupied, but that is unoccupied when the building is unoccupied, without the need for central station monitoring or the equivalent.

A.13.4.1.1 Life safety evaluations are examples of performance-based approaches to life safety. In this respect, significant guidance in the form and process of life safety evaluations is provided by Chapter 5, keeping in mind the fire safety emphasis in Chapter 5. Performance criteria, scenarios, evaluation, safety factors, documentation, maintenance, and periodic assessment (including a warrant of fitness) all apply to the broader considerations in a life safety evaluation. A life safety evaluation deals not only with fire but also with storms, collapse, crowd behavior, and other related safety considerations for which a checklist is provided in A.13.4.1.3. Chapter 5 provides guidance, based on fire safety requirements, for establishing a documented case showing that products of combustion in all conceivable fire scenarios will not significantly endanger occupants using means of egress in the facility (e.g., due to fire detection, automatic suppression, smoke control, large-volume space, or management procedures). Moreover, means of egress facilities plus facility management capabilities should be adequate to cope with scenarios where certain egress routes are blocked for some reason.

In addition to making realistic assumptions about the capabilities of persons in the facility (e.g., an assembled crowd including many disabled persons or persons unfamiliar with the facility), the life safety evaluation should include a factor of safety of not less than 2.0 in all calculations relating to hazard development time and required egress time (the combination of flow time and other time needed to detect and assess an emergency condition, initiate egress, and move along the egress routes). This factor of safety takes into account the possibility that half of the egress routes might not be used (or usable) in certain situations.

Regarding crowd behavior, the potential hazards created by larger masses of people and greater crowd densities (which can be problematic during ingress, occupancy, and egress) demand that technology be used by designers, managers, and authorities responsible for buildings to compensate for the relaxed egress capacity provisions of Table 13.4.2.3. In very large buildings for assembly use, the hazard of crowd crushes can exceed that of fire or structural failure. Therefore, the building designers, managers, event planners, security personnel, police authorities, and fire authorities, as well as the building construction authorities, should understand the potential problems and solutions, including coordination of their activities. For crowd behavior, this understanding includes factors of space, energy, time, and information, as well as specific crowd management techniques, such as metering. Published guidance on these factors and techniques is found in the *SFPE Handbook of Fire Protection Engineering*, Section 3, Chapter 13, pp. 3-342–3-366 (Proulx, G., "Movement of People"), and the publications referenced therein.

Table 13.2.3.2 and Table 13.4.2.3 are based on a linear relationship between number of seats and nominal flow time, with not less than 200 seconds (3.3 minutes) for 2000 seats plus 1 second for every additional 50 seats up to 25,000. Beyond 25,000 total seats, the nominal flow time is limited to 660 seconds (11 minutes). Nominal flow time refers to the flow time for the most able group of patrons; some groups less familiar with the premises or less able groups might take longer to pass a point in the egress system. Although three or more digits are noted in the tables, the resulting calculations should be assumed to provide only two significant figures of precision.

A.13.4.1.3 Factors to be considered in a life safety evaluation might include the following:

(1) Nature of the events being accommodated, including the following:
   (a) Ingress, intra-event movement, and egress patterns
   (b) Ticketing and seating policies/practices
   (c) Event purpose (e.g., sports contest, religious meeting)
   (d) Emotional qualities (e.g., competitiveness) of event
   (e) Time of day when event is held
   (f) Time duration of single event
   (g) Time duration of attendees' occupancy of the building
(2) Occupant characteristics and behavior, including the following:
   (a) Homogeneity
   (b) Cohesiveness
   (c) Familiarity with building
   (d) Familiarity with similar events
   (e) Capability (as influenced by factors such as age, physical abilities)
   (f) Socioeconomic factors
   (g) Small minority involved with recreational violence
   (h) Emotional involvement with the event and other occupants
   (i) Use of alcohol or drugs
   (j) Food consumption
   (k) Washroom utilization
(3) Management, including the following:
   (a) Clear, contractual arrangements for facility operation/use as follows:
      i. Between facility owner and operator
      ii. Between facility operator and event promoter
      iii. Between event promoter and performer
      iv. Between event promoter and attendee
      v. With police forces
      vi. With private security services
      vii. With ushering services

(b) Experience with the building
(c) Experience with similar events and attendees
(d) Thorough, up-to-date operations manual
(e) Training of personnel
(f) Supervision of personnel
(g) Communications systems and utilization
(h) Ratios of management and other personnel to attendees
(i) Location/distribution of personnel
(j) Central command location
(k) Rapport between personnel and attendees
(l) Personnel support of attendee goals
(m) Respect of attendees for personnel due to the following:
    i. Dress (uniform) standards
    ii. Age and perceived experience
    iii. Personnel behavior, including interaction
    iv. Distinction between crowd management and control
    v. Management concern for facility quality (e.g., cleanliness)
    vi. entire event experience of attendees (i.e., not just during occupancy of the building)

(4) Emergency management preparedness, including the following:
(a) Complete range of emergencies addressed in operations manual
(b) Power loss
(c) Fire
(d) Severe weather
(e) Earthquake
(f) Crowd incident
(g) Terrorism
(h) Hazardous materials
(i) Transportation accident (e.g., road, rail, air)
(j) Communications systems available
(k) Personnel and emergency forces ready to respond
(l) Attendees clearly informed of situation and proper behavior

(5) Building systems, including the following:
(a) Structural soundness
(b) Normal static loads
(c) Abnormal static loads (e.g., crowds, precipitation)
(d) Dynamic loads (e.g., crowd sway, impact, explosion, wind, earthquake)
(e) Stability of nonstructural components (e.g., lighting)
(f) Stability of movable (e.g., telescoping) structures
(g) Fire protection
(h) Fire prevention (e.g., maintenance, contents, housekeeping)
(i) Compartmentation
(j) Automatic detection and suppression of fire
(k) Smoke control
(l) Alarm and communications systems
(m) Fire department access routes and response capability
(n) Structural integrity
(o) Weather protection
(p) Wind
(q) Precipitation (attendees rush for shelter or hold up egress of others)
(r) Lightning protection
(s) Circulation systems
(t) Flowline or network analysis
(u) Waywinding and orientation
(v) Merging of paths (e.g., precedence behavior)
(w) Decision/branching points
(x) Route redundancies
(y) Counterflow, crossflow, and queuing situations
(z) Control possibilities, including metering
(aa) Flow capacity adequacy
(bb) System balance
(cc) Movement time performance
(dd) Flow times
(ee) Travel times
(ff) Queuing times
(gg) Route quality
(hh) Walking surfaces (e.g., traction, discontinuities)
(ii) Appropriate widths and boundary conditions
(jj) Handrails, guardrails, and other rails
(kk) Ramp slopes
(ll) Step geometries
(mm) Perceptual aspects (e.g., orientation, signage, marking, lighting, glare, distractions)
(nn) Route choices, especially for vertical travel
(oo) Resting/waiting areas
(pp) Levels of service (overall crowd movement quality)
(qq) Services
(rr) Washroom provision and distribution
(ss) Concessions
(tt) First aid and EMS facilities
(uu) General attendee services

A scenario-based approach to performance-based fire safety is addressed in Chapter 5. In addition to utilizing such scenarios and, more generally, the attention to performance criteria, evaluation, safety factors, documentation, maintenance, and periodic assessment required when the Chapter 5 option is used, life safety evaluations should consider scenarios based on characteristics important in assembly occupancies. These characteristics include the following:

(1) Whether there is a local or mass awareness of an incident, event, or condition that might provoke egress
(2) Whether the incident, event, or condition stays localized or spreads
(3) Whether or not egress is desired by facility occupants
(4) Whether there is a localized start to any egress or mass start to egress
(5) Whether exits are available or not available

Examples of scenarios and sets of characteristics that might occur in a facility follow.

Scenario 1. Characteristics: mass start, egress desired (by management and attendees), exits not available, local awareness.

Normal egress at the end of an event occurs just as a severe weather condition induces evacuees at the exterior doors to retard or stop their egress. The backup that occurs in the egress system is not known to most evacuees, who continue to press forward, potentially resulting in a crowd crush.

Scenario 2. Characteristics: mass start, egress not desired (by management), exits possibly not available, mass awareness.

An earthquake occurs during an event. The attendees are relatively safe in the seating area. The means of egress outside the seating area are relatively unsafe and vulnerable to aftershock damage. Facility management discourages mass egress until the means of egress can be checked and cleared for use.

Scenario 3. Characteristics: local start, incident stays local, egress desired (by attendees and management), exits available, mass awareness.

A localized civil disturbance (e.g., firearms violence) provokes localized egress, which is seen by attendees, generally, who then decide to leave also.

Scenario 4. Characteristics: mass start, egress desired (by attendees), incident spreads, exits not available, mass awareness.

In an open-air facility unprotected from wind, precipitation, and lightning, sudden severe weather prompts egress to shelter but not from the facility. The means of egress congest and block quickly as people in front stop once they are under shelter, while people behind them continue to press forward, potentially resulting in a crowd crush.

These scenarios illustrate some of the broader factors to be taken into account when assessing the capability of both building systems and management features on which reliance is placed in a range of situations, not just fire emergencies. Some scenarios also illustrate the conflicting motivations of management and attendees based on differing perceptions of danger and differing knowledge of hazards, countermeasures, and capabilities. Mass egress might not be the most appropriate life safety strategy in some scenarios, such as Scenario 2.

Table A.13.4.1.3 summarizes the characteristics in the scenarios and provides a framework for developing other characteristics and scenarios that might be important for a particular facility, hazard, occupant type, event, or management.

A.13.4.2 Outdoor facilities are not accepted as inherently smoke-protected but must meet the requirements of smoke-protected assembly seating in order to use the special requirements for means of egress.

A.13.4.6.12 Prior editions of the *Code* required stages to be protected by a Class III standpipe system in accordance with NFPA 14, *Standard for the Installation of Standpipe and Hose Systems.* NFPA 14 requires that Class II and Class III standpipes be automatic — not manual — because they are intended to be used by building occupants. Automatic standpipe systems are required to provide not less than 500 gpm (1890 L/min) at 100 psi (689 kN/m^2). This requirement often can be met only if a fire pump is installed. Installation of a fire pump presents an unreasonable burden for the system supplying the two hose outlets at the side of the stage. The revised wording of 13.4.6.12 offers some relief by permitting the hose outlets to be in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems.*

A.13.4.8 Where a special amusement building is installed inside another building, such as within an exhibit hall, the special amusement building requirements apply only to the special amusement building. For example, the smoke detectors required by 13.4.8.4 are not required to be connected to the building's system. Where installed in an exhibit hall, such smoke detectors are also required to comply with the provisions applicable to an exhibit.

A.13.4.8.1 The aggregate horizontal projections of a multilevel play structure are indicative of the number of children who might be within the structure and at risk from a fire or similar emergency. The word "aggregate" is used in recognition of the fact that the platforms and tubes that make up the multilevel play structure run above each other at various levels. In calculating the area of the projections, it is important to account for all areas that might be expected to be occupied within, on top of, or beneath the components of the structure when the structure is used for its intended function.

A.13.4.8.2 See A.13.4.8.1.

A.13.4.8.7.3 Consideration should be given to the provision of directional exit marking on or adjacent to the floor.

A.13.4.11.2(2) Delayed-egress locks on doors from the airport loading walkway into the airport terminal building might compromise life safety due to the limited period of time the airport loading walkway will provide protection for emergency egress. The requirement of 13.4.11.2(2) would not limit the use of access-controlled or delayed-egress hardware from the airport terminal building into the airport loading walkway.

A.13.7.3(3)(a) Securely supported altar candles in churches that are well separated from any combustible material are permitted. On the other hand, lighted candles carried by children wearing cotton robes present a hazard too great to be permitted. There are many other situations of intermediate hazard where the authority having jurisdiction will have to exercise judgment.

A.13.7.4.1 Fabric applied over unused seating sections should meet the requirements of 13.7.4.

A.13.7.4.3 The phrase "unprotected materials containing foamed plastic" is meant to include foamed plastic items covered by "thermally thin" combustible fabrics or paint. *(See A.10.2.3.4.)*

A.13.7.5.3.7.1(3) See A.13.4.1.1.

A.13.7.6.2 Crowd managers and crowd manager supervisors need to clearly understand the required duties and responsibilities specific to the venue's emergency plan. The crowd management training program should include a clear appreciation of crowd dynamics factors including space, energy, time, and information, as well as specific crowd management techniques, such as metering. Training should involve specific actions necessary during normal and emergency operations, and include an assessment of people-handling capabilities of a space prior to its use, the identification of hazards, an evaluation of projected levels of occupancy, the adequacy of means of ingress and egress and identification of ingress and egress barriers, the processing procedures such as ticket collection,

Table A.13.4.1.3 Life Safety Evaluation Scenario Characteristics Matrix

					Management		Occupants						
Scenario	Local Awareness	Mass Awareness	Incident Localized	Incident Spreads	Egress Desired	Egress Not Desired	Egress Desired	Egress Not Desired	Local Start	Mass Start	Exits Available	Exits Not Available	Other
1	X	—	—	—	X	—	X	—	—	X	—	X	—
2	—	X	—	—	—	X	—	—	—	X	—	X	—
3	—	X	X	—	X	—	X	—	X	—	X	—	—
4	—	X	—	X	—	—	X	—	—	X	—	X	—

and the expected types of human behavior. Training should also involve the different types of emergency evacuations and, where required by the emergency plan, relocation and shelter-in-place operations, and the challenges associated with each.

A.13.7.6.4 In large facilities, crowd managers typically have a specific area of responsibility. In such facilities, the requirements of 13.7.6.4 might apply only to the crowd managers' area of responsibility.

A.13.7.7 It is important that an adequate number of competent attendants is on duty at all times when the assembly occupancy is occupied.

A.13.7.7.3 It is not the intent of this provision to require an announcement in bowling alleys, cocktail lounges, restaurants, or places of worship.

A.14.2.2.3 See 7.2.2.4.5.4 regarding additional handrails on stairs that are used extensively by children 5 years of age or less.

A.14.2.5.9 A corridor roofed over and enclosed on its long side and open to the atmosphere at the end is permitted to be considered an exterior corridor if either of the following criteria are met:

(1) Clear story openings for the corridor are provided on both sides of the corridor and above adjacent roofs or buildings, and such clear openings are not less than one-half the height of the corridor walls.
(2) The corridor roof has unobstructed openings to the sky not less than 50 percent of the area of the roof.

The openings detailed in A.14.2.5.9(1) and (2) are to be equally distributed, and, if louvers are installed, they are to be fixed open with a clear area based on the actual openings between louver vanes.

A.14.2.11.1 It is highly desirable that all windows be of a type that can be readily opened from inside and that they are large enough and low enough for use by students, teachers, and fire fighters. Windows are permitted to serve as a supplementary means of emergency escape, particularly where ladders can be raised by fire fighters or others.

A.14.3.3.2 The definition of interior wall finish is meant to include washroom water closet partitions.

A.14.3.4.2.3.1 Occupied portions of the building should have access to a central point for manual activation of the evacuation signal.

A.14.3.4.2.3.2 Occupied portions of the building should have access to a central point for manual activation of the evacuation signal.

A.14.3.5.1 It is the intent to permit use of the criteria of 8.2.1.3(1) to create separate buildings for purposes of limiting educational occupancy building area to not more than 12,000 ft^2 (1120 m^2).

A.14.7.2.1 The requirements are, of necessity, general in scope, as it is recognized that they apply to all types of educational occupancies as well as conditions of occupancies, such as truant schools; schools for the mentally handicapped, vision impaired, hearing impaired, and speech impaired; and public schools. It is fully recognized that no one code can meet all the conditions of the various buildings involved, and it will be necessary for site administrators to issue supplements to these requirements, but all supplements should be consistent with these requirements.

A.14.7.3.1 Particular attention should be given to keeping all doors unlocked; keeping doors that serve to protect the safety of paths of egress closed and under no conditions blocked open, such as doors on stairway enclosures; keeping outside stairs and fire escape stairs free from all obstructions and clear of snow and ice; and allowing no accumulation of snow or ice or materials of any kind outside exit doors that might prevent the opening of the door or interfere with rapid escape from the building.

Any condition likely to interfere with safe egress should be corrected immediately, if possible, or otherwise should be reported at once to the appropriate authorities.

A.15.2.2.3 See 7.2.2.4.5.4 regarding additional handrails on stairs that are used extensively by children 5 years of age or less.

A.15.2.5.9 A corridor roofed over and enclosed on its long side and open to the atmosphere at the end is permitted to be considered an exterior corridor if either of the following criteria are met:

(1) Clear story openings for the corridor are provided on both sides of the corridor and above adjacent roofs or buildings, and such clear openings are not less than one-half the height of the corridor walls.
(2) The corridor roof has unobstructed openings to the sky not less than 50 percent of the area of the roof.

The openings detailed in A.15.2.5.9(1) are to be equally distributed, and, if louvers are installed, they are to be fixed open with a clear area based on the actual openings between louver vanes.

A.15.2.11.1 It is highly desirable that all windows be of a type that can be readily opened from inside and that they are large enough and low enough for use by students, teachers, and fire fighters. Windows are permitted to serve as a supplementary means of emergency escape, particularly where ladders can be raised by fire fighters or others.

A.15.3.4.2.3.1 Occupied portions of the building should have access to a central point for manual activation of the evacuation signal.

A.15.3.4.2.3.2 Occupied portions of the building should have access to a central point for manual activation of the evacuation signal.

A.15.3.4.3.1.1 The audible occupant notification signal for evacuation of an educational occupancy building should be the distinctive three-pulse temporal pattern fire alarm evacuation signal that is required of new systems by *NFPA 72, National Fire Alarm and Signaling Code.* The temporal pattern will help educate students to recognize the need to evacuate when they are in other occupancies. Existing fire alarm systems should be modified, as feasible, to sound the three-pulse temporal pattern.

A.15.3.6(2) This provision permits valve supervision in accordance with Section 9.7, rather than requiring that the entire automatic sprinkler system be electrically supervised. It is intended that the valve supervision be performed electrically, not by chaining and locking the valves in the open position.

A.15.7.2.1 The requirements are, of necessity, general in scope, as it is recognized that they apply to all types of educational occupancies as well as conditions of occupancies, such as truant schools; schools for the mentally handicapped, vision impaired, hearing impaired, and speech impaired; and public schools. It is fully recognized that no one code can meet all the conditions of the various buildings involved, and it will be necessary for site administrators to issue supplements to these requirements, but all supplements should be consistent with these requirements.

A.15.7.3.1 Particular attention should be given to keeping all doors unlocked; keeping doors that serve to protect the safety of paths of egress closed and under no conditions blocked open, such as doors on stairway enclosures; keeping outside stairs and fire escape stairs free from all obstructions and clear of snow and ice; and allowing no accumulation of snow or ice or materials of any kind outside exit doors that might prevent the opening of the door or interfere with rapid escape from the building.

Any condition likely to interfere with safe egress should be corrected immediately, if possible, or otherwise should be reported at once to the appropriate authorities.

A.16.1.1 Day-care occupancies do not provide for the full-time maintenance of a client. Occupancies that provide a primary place of residence are addressed in other occupancy chapters. *(See Chapters 24 through 33.)*

The requirements of Chapter 16 are based on the need to adequately protect the occupants in case of fire. The requirements assume that adequate staffing will be available and are based on staffing similar to that outlined in Table A.16.1.1.

Table A.16.1.1 Staffing

Staff-to-Client Ratio	Age (mo.)
1:3	0–24
1:4	25–36
1:7	37–60
1:10	61–96
1:12	≥97
1:3	Clients incapable of self-preservation

If staff-to-client ratios fall below those suggested by Table A.16.1.1, it is the responsibility of the authority having jurisdiction to determine the additional safeguards beyond the requirements of Chapter 16 that are necessary. Typical additional provisions might include restricting the day-care occupancy to the level of exit discharge, requiring additional smoke detection, requiring automatic sprinkler protection, requiring better or additional means of egress, and requiring similar types of provisions, depending on the situation.

A.16.1.2.3 A conversion from a day-care occupancy with more than 12 clients to a day-care home is not considered a change of occupancy. The resulting day-care home should be permitted to meet the requirements of Chapter 17 for existing day-care homes.

A.16.2.2.2.4 The purpose of this requirement is to prevent arrangements whereby a client can be trapped in a space or area. It is intended that this provision be broadly interpreted by the authority having jurisdiction to include equipment such as refrigerators and freezers.

A.16.2.2.3 See 7.2.2.4.5.4 regarding additional handrails on stairs that are used extensively by children 5 years of age or less.

A.16.3.2.1(2)(a) It is not the intent to classify a room with a domestic-type clothes washer and a domestic-type clothes dryer as a laundry.

A.16.6.1.4.2 A conversion from a day-care occupancy with more than 12 clients to a day-care home is not considered a change of occupancy. The resulting day-care home should be permitted to meet the requirements of Chapter 17 for existing day-care homes.

A.16.7.1 The requirements are, of necessity, general in scope, because it is recognized that they apply to all types of day-care occupancies as well as conditions of occupancies, such as truant day-care occupancies; occupancies for the mentally handicapped, vision impaired, hearing impaired, and speech impaired; adult day-care; care of infants; and day-care occupancies. It is fully recognized that no one code can meet all the conditions of the various buildings involved, and it will be necessary for site administrators, through the written fire emergency response plan, to issue supplements to these requirements; however, all supplements should be consistent with these requirements. Additionally, it is recommended that fire safety be a part of the educational programs of the occupancy for clients.

Fire emergency response plans need to be written and made available to all employees, including temporary or substitute staff, so that all employees know what is expected of them during a fire emergency. The elements needed in the written plan should be identified in coordination with the authority having jurisdiction.

The facility fire emergency response plan might be a module of a facility disaster plan that covers other emergencies.

The proper safeguarding of clients during a fire emergency requires prompt and effective response by the facility employees in accordance with the fire emergency response plan. Duties covered under the plan should be assigned by position rather than by employee name. Such assignment ensures that, in the absence of an employee, the duties of the position will be performed by a substitute or temporary employee assigned to the position. Temporary or substitute employees should be instructed in advance regarding their duties under the plan for the position to which they are assigned.

Written fire emergency response plans should include, but should not be limited to, information for employees regarding methods and devices available for alerting occupants of a fire emergency. Employees should know how the fire department is to be alerted. Even where automatic systems are expected to alert the fire department, the written plan should provide for backup alerting procedures by staff. Other responses of employees to a fire emergency should include the following:

(1) Removal of clients in immediate danger to areas of safety, as set forth in the plan
(2) Methods of using building features to confine the fire and its byproducts to the room or area of origin
(3) Control of actions and behaviors of clients during removal or evacuation activities and at predetermined safe assembly areas

The written plan should state clearly the facility policy regarding the actions staff are to take or not take to extinguish a fire. It should also incorporate the emergency egress and relocation drill procedures set forth in 16.7.2.

For additional guidance on emergency action plans, see *NFPA 1600, Standard on Disaster/Emergency Management and Business Continuity Programs*. This standard establishes a common set of criteria for disaster management, emergency management, and business continuity programs.

A.16.7.2.1 The requirements are, of necessity, general in scope, because it is recognized that they apply to all types of day-care occupancies as well as conditions of occupancies, such as truant day-care occupancies; and day-care occupancies for the mentally handicapped, vision impaired, hearing impaired, and speech impaired. It is fully recognized that no one code can meet all the conditions of the various buildings involved, and it will be necessary for site administrators to issue supplements to these requirements, but all supplements should be consistent with these requirements.

A.16.7.3.2 Particular attention should be given to keeping all doors unlocked; keeping doors that serve to protect the safety of paths of egress closed and under no conditions blocked open, such as doors on stairway enclosures; keeping outside stairs and fire escape stairs free from all obstructions and clear of snow and ice; and allowing no accumulation of snow or ice or materials of any kind outside exit doors that might prevent the opening of the door or interfere with rapid escape from the building.

A.16.7.5 It is the intent that the requirement for adequate adult staff to be awake at all times when clients are present be applied to family day-care and group day-care homes that are operated at night, as well as day-care occupancies.

A.17.1.1 Day-care occupancies do not provide for the full-time maintenance of a client. Occupancies that provide a primary place of residence are addressed in other occupancies. *(See Chapters 24 through 33.)*

The requirements of Chapter 17 are based on the need to adequately protect the occupants in case of fire. The requirements assume that adequate staffing will be available and are based on staffing similar to that outlined in Table A.17.1.1.

Table A.17.1.1 Staffing

Staff-to-Client Ratio	Age (mo.)
1:3	0–24
1:4	25–36
1:7	37–60
1:10	61–96
1:12	≥97
1:3	Clients incapable of self-preservation

If staff-to-client ratios fall below those suggested by Table A.17.1.1, it is the responsibility of the authority having jurisdiction to determine the additional safeguards beyond the requirements of Chapter 17 that are necessary. Typical additional provisions might include restricting the day-care occupancy to the level of exit discharge, requiring additional smoke detection, requiring automatic sprinkler protection, requiring better or additional means of egress, and requiring similar types of items, depending on the situation.

A.17.1.2.3 A conversion from a day-care occupancy with more than 12 clients to a day-care home is not considered a change of occupancy. The resulting day-care home should be permitted to meet the requirements of Chapter 17 for existing day-care homes.

A.17.2.2.2.4 The purpose of this requirement is to prevent arrangements where a client can be trapped in a space or area. It is intended that this provision be broadly interpreted by the authority having jurisdiction to include equipment such as refrigerators and freezers.

A.17.2.2.3 See 7.2.2.4.5.4 regarding additional handrails on stairs that are used extensively by children 5 years of age and under.

A.17.3.2.1(2)(a) It is not the intent to classify a room with a domestic-type clothes washer and a domestic-type clothes dryer as a laundry.

A.17.6.1.1.2 Day-care homes do not provide for the full-time maintenance of a client. Day-care occupancies that provide a primary place of residence are addressed in other occupancy chapters. *(See Chapters 24 through 33.)*

A.17.6.1.4.2 A conversion from a day-care occupancy with more than 12 clients to a day-care home is not considered a change of occupancy. The resulting day-care home should be permitted to meet the requirements of Chapter 17 for existing day-care homes.

A.17.7.1 The requirements are, of necessity, general in scope, because it is recognized that they apply to all types of day-care occupancies as well as conditions of occupancies, such as truant day-care occupancies; occupancies for the mentally handicapped, vision impaired, hearing impaired, and speech impaired; adult day-care; care of infants; and day-care occupancies. It is fully recognized that no one code can meet all the conditions of the various buildings involved, and it will be necessary for site administrators, through the written fire emergency response plan, to issue supplements to these requirements; however, all supplements should be consistent with these requirements. Additionally, it is recommended that fire safety be a part of the educational programs of the occupancy for clients.

Fire emergency response plans need to be written and made available to all employees, including temporary or substitute staff, so that all employees know what is expected of them during a fire emergency. The elements needed in the written plan should be identified in coordination with the authority having jurisdiction.

The facility fire emergency response plan might be a module of a facility disaster plan that covers other emergencies.

The proper safeguarding of clients during a fire emergency requires prompt and effective response by the facility employees in accordance with the fire emergency response plan. Duties covered under the plan should be assigned by position rather than by employee name. Such assignment ensures that, in the absence of an employee, the duties of the position will be performed by a substitute or temporary employee assigned to the position. Temporary or substitute employees should be instructed in advance regarding their duties under the plan for the position to which they are assigned.

Written fire emergency response plans should include, but should not be limited to, information for employees about methods and devices available for alerting occupants of a fire emergency. Employees should know how the fire department is to be alerted. Even where automatic systems are expected to alert the fire department, the written plan should provide for backup alerting procedures by staff. Other responses of employees to a fire emergency should include the following:

(1) Removal of clients in immediate danger to areas of safety, as set forth in the plan

(2) Methods of using building features to confine the fire and its byproducts to the room or area of origin
(3) Control of actions and behaviors of clients during removal or evacuation activities and at predetermined safe assembly areas

The written plan should state clearly the facility policy regarding the actions staff are to take or not take to extinguish a fire. It should also incorporate the emergency egress and relocation drill procedures set forth in 17.7.2.

For additional guidance on emergency action plans, see *NFPA 1600, Standard on Disaster/Emergency Management and Business Continuity Programs*. This standard establishes a common set of criteria for disaster management, emergency management, and business continuity programs.

A.17.7.2.1 The requirements are, of necessity, general in scope, because it is recognized that they apply to all types of day-care occupancies as well as conditions of occupancies, such as truant day-care occupancies; and day-care occupancies for the mentally handicapped, vision impaired, hearing impaired, and speech impaired. It is fully recognized that no one code can meet all the conditions of the various buildings involved, and it will be necessary for site administrators to issue supplements to these requirements, but all supplements should be consistent with these requirements.

A.17.7.3.2 Particular attention should be given to keeping all doors unlocked; keeping doors that serve to protect the safety of paths of egress closed and under no conditions blocked open, such as doors on stairway enclosures; keeping outside stairs and fire escape stairs free from all obstructions and clear of snow and ice; and allowing no accumulation of snow or ice or materials of any kind outside exit doors that might prevent the opening of the door or interfere with rapid escape from the building.

A.17.7.5 It is the intent that the requirement for adequate adult staff to be awake at all times when clients are present be applied to family day-care and group day-care homes that are operated at night, as well as day-care occupancies.

A.18.1.1.1.1 In determining equivalency for conversions, modernizations, renovations, or unusual design concepts of hospitals or nursing homes, the authority having jurisdiction is permitted to accept evaluations based on the health care occupancies for safety evaluation system (FSES) of NFPA 101A, *Guide on Alternative Approaches to Life Safety*, utilizing the parameters for new construction.

A.18.1.1.1.7 There are many reasons why doors in the means of egress in health care occupancies might need to be locked for the protection of the patients or the public. Examples of conditions that might justify door locking include dementia, mental health, infant care, pediatric care, or patients under court detention order requiring medical treatment in a health care facility. See 18.2.2.2.5 for details on door locking.

A.18.1.1.1.10 The *Code* recognizes that certain functions necessary for the life safety of building occupants — such as the detection of fire and associated products of combustion, the closing of corridor doors, the operation of manual fire alarm devices, and the removal of patients from the room of fire origin — require the intervention of facility staff. It is not the intent of 18.1.1.1.10 to specify the levels or locations of staff necessary to meet this requirement.

A.18.1.1.2 This objective is accomplished in the context of the physical facilities, the type of activities undertaken, the provisions for the capabilities of staff, and the needs of all occupants through requirements directed at the following:

(1) Prevention of ignition
(2) Detection of fire
(3) Control of fire development
(4) Confinement of the effects of fire
(5) Extinguishment of fire
(6) Provision of refuge or evacuation facilities, or both
(7) Staff reaction

A.18.1.1.4.3.3 For the purpose of this requirement, a floor that is not divided by a smoke barrier is considered one smoke compartment. Where automatic sprinklers are retrofitted into existing nonsprinklered buildings, the construction alternatives for sprinklers provided in this *Code* are intended to apply to the renovated area.

A.18.1.1.4.3.4 In minor rehabilitation, only the rehabilitation itself — not the entire smoke compartment or building — is required to be brought up to the requirements for new nonsprinklered facilities.

A.18.1.3.4 Doctors' offices and treatment and diagnostic facilities that are intended solely for outpatient care and are physically separated from facilities for the treatment or care of inpatients, but that are otherwise associated with the management of an institution, might be classified as business occupancies rather than health care occupancies. Facilities that do not provide housing for patients on a 24-hour basis are required to be classified as other than health care occupancies per 18.1.1.1.9, except where services are provided routinely to four or more inpatients who are incapable of self-preservation.

A.18.1.3.5.1 It is the intent that these requirements apply to mobile, transportable, and relocatable structures (in accordance with 1.3.2) where such structures are used to provide shared medical services on an extended or a temporary basis. Where properly separated from the health care occupancy and intended to provide services simultaneously for three or fewer health care patients who are litterborne, the level of protection for such structures should be based on the appropriate occupancy classification of other chapters of this *Code*. Mobile, transportable, or relocatable structures that are not separated from a contiguous health care occupancy, or that are intended to provide services simultaneously for four or more health care patients who are litterborne, should be classified and designed as health care occupancies.

A.18.2.2 In planning egress, arrangements should be made to transfer patients from one section of a floor to another section of the same floor that is separated by a fire barrier or smoke barrier in such a manner that patients confined to their beds can be transferred in their beds. Where the building design will allow, the section of the corridor containing an entrance or elevator lobby should be separated from corridors leading from it by fire or smoke barriers. Such arrangement, where the lobby is centrally located, will, in effect, produce a smoke lock, placing a double barrier between the area to which patients might be taken and the area from which they need to be evacuated because of threatening smoke and fire.

A.18.2.2.2.4(2) Where delayed-egress locks complying with 7.2.1.6.1 are used, the provisions of 18.2.2.2.5 are not required.

A.18.2.2.2.4(3) Where access-controlled egress doors complying with 7.2.1.6.2 are used, the provisions of 18.2.2.2.5 are not required.

A.18.2.2.2.5.1 Psychiatric units, Alzheimer units, and dementia units are examples of areas with patients who might have clinical needs that justify door locking. Forensic units and detention units are examples of areas with patients who might pose a security threat. Where Alzheimer or dementia patients in nursing homes are not housed in specialized units, the provisions of 18.2.2.2.5.1 should not apply. *(See 18.2.2.2.5.2.)*

A.18.2.2.2.5.2 Pediatric units, maternity units, and emergency departments are examples of areas where patients might have special needs that justify door locking. Door locking arrangements should be permitted to reduce the risk of abduction of infants and children who are patients.

A.18.2.2.2.5.2(3) Where locked doors in accordance with 18.2.2.2.5.2 are proposed for an existing building that is not sprinklered throughout, the authority having jurisdiction might consider permitting the installation based on an analysis of the extent of sprinkler protection provided. Sprinklered areas should include, at a minimum, the secured compartment and compartments that the occupants of the secured compartment must travel through to egress the building.

A.18.2.2.2.7 In some health care occupancies, especially nursing homes, the use of murals to disguise doors has been found to be beneficial for certain patient populations. This provision is intended to apply to disguising of egress doors by painting the doors or the use of wall paper on the doors. The marking of the means of egress such as required exit signs should be clearly visible and not disguised by the mural. Where decorations are applied to the door, the requirements of Section 18.7 would still apply and painting a mural on the door would not be considered a decoration. Such murals should not obscure required vision panels or affect the required fire resistance rating of fire-rated door assemblies.

A.18.2.2.2.7(2) It is intended that the door-releasing hardware includes levers, locks, knobs, and panic bars, that are directly operated or grasped by staff.

A.18.2.2.2.7(3) It is intended that the door hardware that is permitted to be covered (i.e., disguised by the mural) includes items such as hinges, closers, and magnets, which would normally not be directly operated or grasped by staff.

A.18.2.2.2.8 It is desirable to keep doors in exit passageways, stair enclosures, horizontal exits, smoke barriers, and required enclosures around hazardous areas closed at all times to impede the travel of smoke and fire gases. Functionally, however, this involves decreased efficiency and limits patient observation by the staff of a facility. To accommodate such needs, it is practical to presume that such doors will be kept open, even to the extent of employing wood chocks and other makeshift devices. Doors in exit passageways, horizontal exits, and smoke barriers should, therefore, be equipped with automatic hold-open devices activated by the methods described, regardless of whether the original installation of the doors was predicated on a policy of keeping them closed.

A.18.2.3.4 It is not the intent that the required corridor width be maintained clear and unobstructed at all times. Projections into the required width are permitted by 7.3.2.2. It is not the intent that 18.2.3.4 supersede 7.3.2.2.

A.18.2.3.4(1) Occupant characteristics are an important factor to be evaluated in setting egress criteria. Egress components in nonpatient use areas, such as administrative office spaces, should be evaluated based on actual use. A clear corridor width of not less than 44 in. (1120 mm) is specified, assuming occupants in nonpatient areas will be mobile and capable of evacuation without assistance.

A.18.2.3.4(2) The intent of 18.2.3.4 is to permit limited noncontinuous projections along the corridor wall. These include hand-rub dispensing units complying with 18.3.2.6, nurse charting units, wall-mounted computers, telephones, artwork, bulletin boards, display case frames, cabinet frames, fire alarm boxes, and similar items. It is not the intent to permit the narrowing of the corridor by the walls themselves. The provision of 7.3.2.2 permits projections up to 4½ in. (114 mm) to be present at and below the 38 in. (965 mm) height specified in 18.2.3.4(2), and it is not the intent of 18.2.3.4 (2) to prohibit such projections. Permitting projections above the 38 in. (965 mm) handrail height complies with the intent of the requirement, as such projections will not interfere with the movement of gurneys, beds, and wheelchairs. Projections below handrail height for limited items, such as fire extinguisher cabinets and recessed water coolers, also will not interfere with equipment movement.

Building codes and accessibility codes might require cane detection below projections that exceed 4 in. (102 mm).

A.18.2.3.4(3) Exit access should be arranged to avoid any obstructions to the convenient removal of nonambulatory persons carried on stretchers or on mattresses serving as stretchers.

A.18.2.3.4(4)(c) Wheeled equipment and carts in use include food service carts, housekeeping carts, medication carts, isolation carts, and similar items. Isolation carts should be permitted in the corridor only where patients require isolation precautions.

Unattended wheeled crash carts and other similar wheeled emergency equipment are permitted to be located in the corridor when "not in use," because they need to be immediately accessible during a clinical emergency. Note that "not in use" is not the same as "in storage." Storage is not permitted to be open to the corridor, unless it meets one of the provisions permitted in 18.3.6.1 and is not a hazardous area.

Wheeled portable patient lift or transport equipment needs to be readily available to clinical staff for moving, transferring, toileting, or relocating patients. These devices are used daily for safe handling of patients and to provide for worker safety. This equipment might not be defined as "in use" but needs to be convenient for the use of caregivers at all times.

A.18.2.3.4(5) The means for affixing the furniture can be achieved with removable brackets to allow cleaning and maintenance. Affixing the furniture to the floor or wall prevents the furniture from moving, so as to maintain a minimum 6 ft (1830 mm) corridor clear width. Affixing the furniture to the floor or wall also provides a sturdiness that allows occupants to safely transfer in and out.

A.18.2.3.4(5)(f) Examples of building service and fire protection equipment include fire extinguishers, manual fire alarm boxes, shutoff valves, and similar equipment.

A.18.2.3.4(6) The 8 ft (2440 mm) corridor width does not need to be maintained at the door or the open door leaf. A reduction for the frame and leaf is acceptable as long as the minimum clear width is provided at the door opening in the direction of egress travel. In situations where egress occurs only in one direction, it is permissible to have a single door leaf.

A.18.2.3.5(1) See A.18.2.3.4(1).

A.18.2.3.5(2) The intent of 18.2.3.5 is to permit limited noncontinuous projections along the corridor wall. These include hand-rub dispensing units complying with 18.3.2.6, nurse charting units, wall-mounted computers, telephones, artwork, bulletin boards, display case frames, cabinet frames, fire alarm boxes, and similar items. It is not the intent to permit the narrowing of the corridor by the walls themselves. The provision of 7.3.2.2 permits projections up to 4½ in. (114 mm) to be present at and below the 38 in. (965 mm) height specified in 18.2.3.5(2), and it is not the intent of 18.2.3.5(2) to prohibit such projections. Permitting projections above the 38 in. (965 mm) handrail height complies with the intent of the requirement, as such projections will not interfere with the movement of gurneys, beds, and wheelchairs. Projections below handrail height for limited items, such as fire extinguisher cabinets and recessed water coolers, also will not interfere with equipment movement.

Building codes and accessibility codes might require cane detection below projections that exceed 4 in. (102 mm).

A.18.2.3.5(3) See A.18.2.3.4(3)(3).

A.18.2.3.5(4)(c) Wheeled equipment and carts in use include food service carts, housekeeping carts, medication carts, isolation carts, and similar items. Isolation carts should be permitted in the corridor only where patients require isolation precautions.

Unattended wheeled crash carts and other similar wheeled emergency equipment are permitted to be located in the corridor when "not in use," because they need to be immediately accessible during a clinical emergency. Note that "not in use," is not the same as "in storage." Storage is not permitted to be open to the corridor, unless it meets one of the provisions permitted in 18.3.6.1 and is not a hazardous area.

Wheeled portable patient lift or transport equipment needs to be readily available to clinical staff for moving, transferring, toileting, or relocating patients. These devices are used daily for safe handling of patients and to provide for worker safety. This equipment might not be defined as "in use" but needs to be convenient for the use of caregivers at all times.

A.18.2.3.5(5) The 6 ft 1830 mm) corridor width does not need to be maintained at the door or the open door leaf. A reduction for the frame and leaf is acceptable as long as the minimum clear width is provided at the door opening in the direction of egress travel. In situations where egress occurs only in one direction, it is permissible to have a single door leaf.

A.18.2.4.4 An exit is not necessary for each individual smoke compartment if there is access to an exit through other smoke compartments without passing through the smoke compartment of fire origin.

A.18.2.5.4 The term *intervening rooms or spaces* means rooms or spaces serving as a part of the required means of egress from another room.

A.18.2.5.6.1 For the purposes of this paragraph, it is the intent that the term *habitable rooms* not include individual bathrooms, closets, and similar spaces, as well as briefly occupied work spaces, such as control rooms in radiology and small storage rooms in a pharmacy.

A.18.2.5.7.1.2 Two or more contiguous suites with an aggregate area not exceeding the suite size limitations of 18.2.5.7.2.3 and 18.2.5.7.3.3 are permitted to be considered a single suite, so as not to require separation from each other.

A.18.2.5.7.1.3(A) The term *intervening room* means a room serving as a part of the required means of egress from another room.

A.18.2.5.7.1.3(C) Examples of suites that might be hazardous areas are medical records and pharmaceutical suites.

A.18.2.5.7.2.1(B) Supervision of sleeping suites is accomplished by direct supervision by staff, smoke detection, or a combination of direct supervision and smoke detection. The following three options are available for meeting the supervision requirements for patient sleeping suites having an area not exceeding 7500 ft^2 (700 m^2):

(1) Direct supervision of all sleeping rooms by staff from a normally attended location within the suite [in accordance with 18.2.5.7.2.1(B)(1)(a)].
(2) Supervision of those sleeping rooms that can be directly supervised [in accordance with 18.2.5.7.2.1(B)(1)(a)] and smoke detection provided in the sleeping rooms that cannot be directly supervised [in accordance with 18.2.5.7.2.1(B)(1)(b)] as depicted in Figure A.18.2.5.7.2.1(B)(a).
(3) Total (complete) coverage smoke detection throughout the sleeping suite [in accordance with 18.2.5.7.2.1(B)(2)] as depicted in Figure A.18.2.5.7.2.1(B)(b).

Where the option for total (complete) coverage smoke detection is used, the provision of 9.6.2.9 requires detectors in all occupiable areas that are suitable for smoke detector operation. For example, an area subject to shower steam would not require a smoke detector.

For patient sleeping suites having an area greater than 7500 ft^2 (700 m^2), both direct supervision by staff and total (complete) coverage smoke detection throughout the sleeping suite are required [in accordance with 18.2.5.7.2.3(C)] as depicted in Figure A.18.2.5.7.2.1(B)(c).

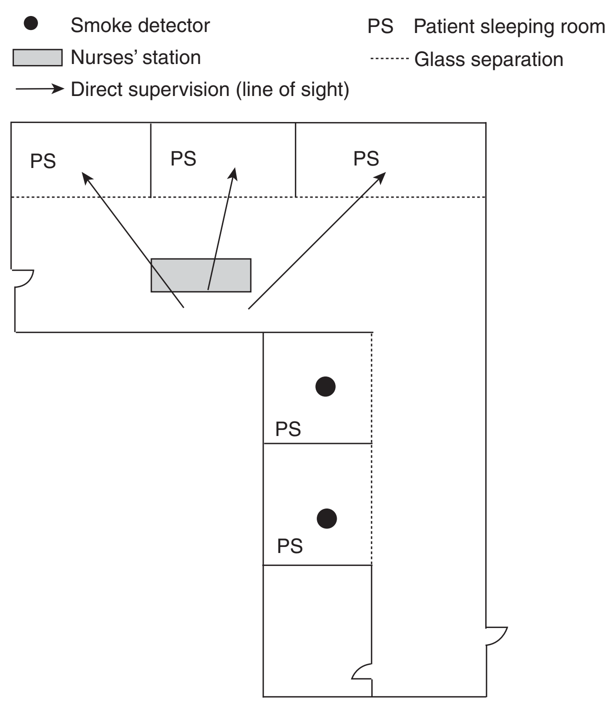

FIGURE A.18.2.5.7.2.1(B)(a) All Sleeping Rooms Provided Either with Direct Supervision by Staff or Smoke Detection.

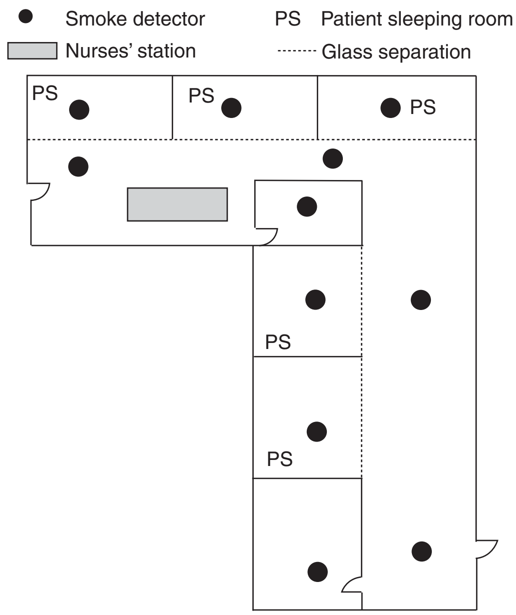

FIGURE A.18.2.5.7.2.1(B)(b) Supervision Provided by Total (Complete) Smoke Detection Throughout the Sleeping Suite.

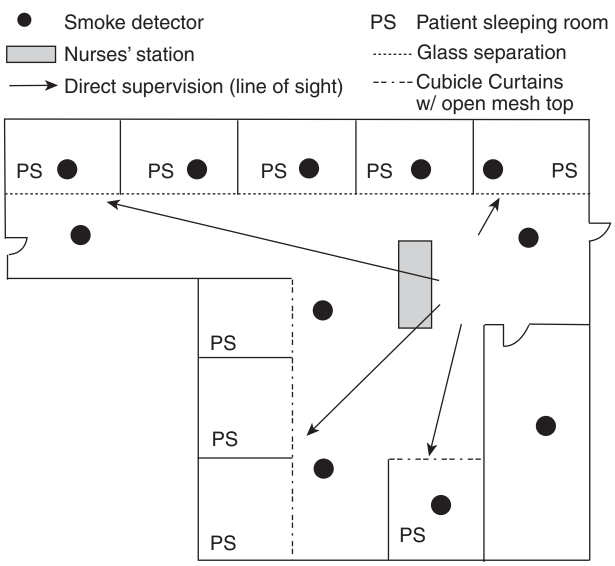

FIGURE A.18.2.5.7.2.1(B)(c) For Suites >7500 ft^2 (>700 m^2), All Sleeping Rooms Must Be Provided with Direct Supervision by Staff and Total (Complete) Smoke Detection Installed Throughout the Sleeping Suite.

A.18.2.5.7.2.1(B)(1) The interior partitions or walls might extend full height to the ceiling, provided that they do not obscure visual supervision of the suite. Where they do obscure visual supervision, see 18.2.5.7.2.1(B)(2).

A.18.2.5.7.2.2(A) Where only one means of egress is required from the suite, it needs to be provided by a door opening directly to a corridor complying with 18.3.6 or to a horizontal exit.

A.18.2.5.7.2.2(C) Where the second exit access for a sleeping suite is through an adjacent suite, it is the intent that the 100 ft (30 m) travel distance limitation in the suite be applied only to the suite under consideration.

A.18.2.5.7.2.3(C)(1) The alternative of 18.2.5.7.2.1(D)(1)(b) is not to be applied, since 18.2.5.7.2.3(C)(2) requires total coverage automatic smoke detection for the suite that exceeds 7500 ft^2 (700 m^2) but does not exceed 10,000 ft^2 (930 m^2).

A.18.2.5.7.3.1(C) Where the second exit access for a nonsleeping suite is through an adjacent suite, it is the intent that the adjacent suite not be considered an intervening room.

A.18.3.2.5.2 This provision is intended to permit appliances used for reheating, limited cooking, and food preparation, such as microwave ovens, hot plates, electric skillets, toasters, and nourishment centers to be exempt from the requirements for commercial cooking equipment and hazardous area protection. Limited quantities of butter, cooking spray, or oil can be used.

A.18.3.2.5.3 The intent of 18.3.2.5.3 is to limit the number of persons for whom meals are routinely prepared to not more than 30. Staff and feeding assistants are not included in this number.

A.18.3.2.5.3(3) The minimum airflow of 500 cfm (14,000 L/m) is intended to require the use of residential hood equipment at the higher end of equipment capacities. It is also intended to draw a sufficient amount of the cooking vapors into the grease baffle and filter system to reduce migration beyond the hood.

A.18.3.2.5.3(6) The intent of this provision is to limit cooking fuel to gas or electricity. The prohibition of solid fuels for cooking is not intended to prohibit charcoal grilling on grills located outside the facility.

A.18.3.2.5.3(9) The intent of this requirement is that the fuel source for the cooktop or range is to be turned on only when staff is present or aware that the kitchen is being used. The timer function is meant to provide an additional safeguard if the staff forgets to deactivate the cooktop or range. If a cooking activity lasts longer than 120 minutes, the timer would be required to be manually reset.

A.18.3.2.5.3(11) Protection of the cooktop or range is accomplished by the sprinklers that are required in the space and the required cooktop hood fire suppression system. The smoke alarms are intended to notify staff who might not be in the immediate area. Smoke alarms should be maintained a minimum of 20 ft (6.1 m) away from the cooktop or range as studies have shown this distance to be the threshold for significantly reducing nuisance alarms caused by cooking. The intent of the interconnected smoke alarms, with silence feature, is that while the devices would alert staff members to a potential problem, if it is a nuisance alarm, the staff members can use the silence feature instead of disabling the alarm. The referenced study indicates that nuisance alarms are reduced with photoelectric smoke alarms. Providing two interconnected alarms provides a safety factor since they are not electrically supervised by the fire alarm system. *(Smoke Alarms – Pilot Study of Nuisance Alarms Associated with Cooking)*

A.18.3.2.5.3(12) The provision of 18.3.2.5.3(12) recognizes that it is more important to maintain the 20 ft (6.1 m) minimum spacing criterion between the smoke alarm and the cooktop or range, to minimize nuisance alarms, than to assure that the smoke alarm is located within the kitchen area itself.

A.18.3.2.5.3(13) The requirements of 18.3.2.5.3(13) are intended to allow the local staff to silence and reset the system smoke detector without the assistance of the engineering or maintenance personnel. This provision is not intended to require the system smoke detector to initiate a building-wide occupant alarm signal or to notify the emergency forces.

A.18.3.2.5.4 The provisions of 18.3.2.5.4 differ from those of 18.3.2.5.3, as they apply to cooking equipment that is separated from the corridor.

A.18.3.2.5.5 The provision of 18.3.2.5.5 clarifies that protected commercial cooking equipment does not require an enclosure (separation) as a hazardous area in accordance with Section 8.7, as is required by 18.3.2.1.

A.18.3.3.2 The reductions in class of interior finish prescribed by 10.2.8.1 are permitted to be used.

A.18.3.4.2 It is not the intent of this *Code* to require single-station smoke alarms that might be required by local codes to be connected to or to initiate the building fire alarm system.

A.18.3.4.3.1(2) It is the intent of this provision to permit a visible fire alarm signal instead of an audible signal to reduce interference between the fire alarm and medical equipment monitoring alarms.

A.18.3.4.5.3 The requirement for smoke detectors in spaces open to the corridors eliminates the requirements of 18.3.6.1(1)(c), (2)(b), and (5)(b) for direct supervision by the facility staff of nursing homes.

A.18.3.5.1 In areas where the replenishment of water supplies is not immediately available from on-site sources, alternate provisions for the water-fill rate requirements of NFPA 13, *Standard for the Installation of Sprinkler Systems*, and NFPA 22, *Standard for Water Tanks for Private Fire Protection*, that are acceptable to the authority having jurisdiction should be provided. Appropriate means for the replenishment of these supplies from other sources, such as fire department tankers, public safety organizations, or other independent contractors should be incorporated into the overall fire safety plan of the facility.

With automatic sprinkler protection required throughout new health care facilities and quick-response sprinklers required in smoke compartments containing patient sleeping rooms, a fire and its life-threatening byproducts can be reduced, thereby allowing the defend-in-place concept to continue. The difficulty in maintaining the proper integrity of life safety elements has been considered, and it has been judged that the probability of a sprinkler system operating as designed is equal to or greater than other life safety features.

A.18.3.5.6 The requirements for use of quick-response sprinklers intend that quick-response sprinklers be the predominant type of sprinkler installed in the smoke compartment. It is recognized, however, that quick-response sprinklers might not be approved for installation in all areas, such as those where NFPA 13, *Standard for the Installation of Sprinkler Systems*, requires sprinklers of the intermediate- or high-temperature classification. It is not the intent of the 18.3.5.6 requirements to prohibit the use of standard sprinklers in limited areas of a smoke compartment where intermediate- or high-temperature sprinklers are required.

Residential sprinklers are considered acceptable in patient sleeping rooms of all health care facilities, even though not specifically listed for this purpose in all cases.

Where the installation of quick-response sprinklers is impracticable in patient sleeping room areas, appropriate equivalent protection features acceptable to the authority having jurisdiction should be provided. It is recognized that the use of quick-response sprinklers might be limited in facilities housing certain types of patients or by the installation limitations of quick-response sprinklers.

A.18.3.5.10 This exception is limited to hospitals, as nursing homes and many limited care facilities might have more combustibles within the closets. The limited amount of clothing found in the small clothes closets in hospital patient rooms is typically far less than the amount of combustibles in casework cabinets that do not require sprinkler protection, such as nurse servers. In many hospitals, especially new hospitals, it is difficult to make a distinction between clothes closets and cabinet work. The exception is far more restrictive than similar exceptions for hotels and apartment buildings. NFPA 13, *Standard for the Installation of Sprinkler Systems,* already permits the omission of sprinklers in wardrobes [see 8.1.1(7) of NFPA 13]. It is not the intent of 18.3.5.10 to affect the wardrobe provisions of NFPA 13. It is the intent that the sprinkler protection in the room covers the closet as if there were no door on the closet. *(See 8.5.3.2.3 of NFPA 13.)*

A.18.3.5.11 For the proper operation of sprinkler systems, cubicle curtains and sprinkler locations need to be coordinated. Improperly designed systems might obstruct the sprinkler spray from reaching the fire or might shield the heat from the sprinkler. Many options are available to the designer including, but not limited to, hanging the cubicle curtains 18 in. (455 mm) below the sprinkler deflector; using a ½ in. (13 mm) diagonal mesh or a 70 percent open weave top panel that extends 18 in. (455 mm) below the sprinkler deflector; or designing the system to have a horizontal and minimum vertical distance that meets the requirements of NFPA 13, *Standard for the Installation of Sprinkler Systems.* The test data that form the basis of the NFPA 13 requirements are from fire tests with sprinkler discharge that penetrated a single privacy curtain.

A.18.3.6.1(1)(a) The presence of stored combustible materials in a room or space open to the corridor does not necessarily result in the room or space being classified as a hazardous area. In some circumstances, the amount and type of combustibles might result in the room or space being classified as a hazardous area by the authority having jurisdiction.

A.18.3.6.1(3) A typical nurses' station would normally contain one or more of the following with associated furniture and furnishings:

(1) Charting area
(2) Clerical area
(3) Nourishment station
(4) Storage of small amounts of medications, medical equipment and supplies, clerical supplies, and linens
(5) Patient monitoring and communication equipment

A.18.3.6.2 It is the intent of the *Code* that there be no required fire resistance or area limitations for vision panels in corridor walls and doors.

An architectural, exposed, suspended-grid acoustical tile ceiling with penetrating items, such as sprinkler piping and sprinklers; ducted HVAC supply and return-air diffusers; speakers; and recessed lighting fixtures, is capable of limiting the transfer of smoke.

A.18.3.6.2.3 While a corridor wall is required to form a barrier to limit the transfer of smoke, such a barrier is not required to be either a smoke barrier or a smoke partition — two terms for which specific *Code* definitions and requirements apply.

A.18.3.6.3 While it is recognized that closed doors serve to maintain tenable conditions in a corridor and adjacent patient rooms, such doors, which, under normal or fire conditions, are self-closing, might create a special hazard for the personal safety of a room occupant. Such closed doors might present a problem of delay in discovery, confining fire products beyond tenable conditions.

Because it is critical for responding staff members to be able to immediately identify the specific room involved, it is recommended that approved automatic smoke detection that is interconnected with the building fire alarm be considered for rooms having doors equipped with closing devices. Such detection is permitted to be located at any approved point within the room. When activated, the detector is required to provide a warning that indicates the specific room of involvement by activation of a fire alarm annunciator, nurse call system, or any other device acceptable to the authority having jurisdiction.

Where a nurse server penetrates a corridor wall, the access opening on the corridor side of the nurse server must be protected as is done for a corridor door.

A.18.3.6.3.1 Gasketing of doors should not be necessary to achieve resistance to the passage of smoke if the door is relatively tight-fitting.

A.18.3.6.3.10 Doors should not be blocked open by furniture, door stops, chocks, tie-backs, drop-down or plunger-type devices, or other devices that necessitate manual unlatching or releasing action to close. Examples of hold-open devices that release when the door is pushed or pulled are friction catches or magnetic catches.

A.18.3.6.3.12 It is not the intent of 18.3.6.3.12 to prohibit the application of push plates, hardware, or other attachments on corridor doors in health care occupancies.

A.18.3.6.5.1 It is not the intent of 18.3.6.5.1 to permit mail slots or pass-through openings in doors or walls of rooms designated as a hazardous area.

A.18.3.7 See A.18.2.2.

A.18.3.7.3(2) Where the smoke control system design requires dampers so that the system will function effectively, it is not the intent of the provision to permit the damper to be omitted.

This provision is not intended to prevent the use of plenum returns where ducting is used to return air from a ceiling plenum through smoke barrier walls. Short stubs or jumper ducts are not acceptable. Ducting is required to connect at both sides of the opening and to extend into adjacent spaces away from the wall. The intent is to prohibit open-air transfers at or near the smoke barrier walls.

A.18.3.7.6 Smoke barrier doors are intended to provide access to adjacent zones. The pair of cross-corridor doors are required to be opposite swinging. Access to both zones is required.

It is not the intent of 18.3.7.6 to prohibit the application of push plates, hardware, or other attachments on some barrier doors in health care occupancies. The provision of 18.3.7.6 requires the door leaves to be of substantial construction that is sufficient to resist fire for 20 minutes. Non-labeled 1¾ in. (44 mm) solid, bonded wood-core doors that are used in place of labeled 20-minute fire doors are not subject to the requirements of NFPA 80, *Standard for Fire Doors and Other Opening Protectives*, therefore, nonrated factory or field-applied protective plates unlimited in height are permitted.

A.18.3.7.8 Smoke barriers might include walls having door openings other than cross-corridor doors. There is no restriction in the *Code* regarding which doors or how many doors form part of a smoke barrier. For example, doors from the corridor to individual rooms are permitted to form part of a smoke barrier. Split astragals (i.e., astragals installed on both door leaves) are also considered astragals.

A.18.3.7.9 It is not the intent to require the frame to be a listed assembly.

A.18.4.3 Extensive research, including fire modeling, has indicated that alcohol-based hand-rub solutions can be safely installed in corridors of health care facilities, provided that certain other precautions are taken. The total quantities of flammable liquids in any area should comply with the provisions of other recognized codes, including NFPA 1, *Fire Code*, and NFPA 30, *Flammable and Combustible Liquids Code*. In addition, special consideration should be given to the following:

(1) Obstructions created by the installation of hand-rub solution dispensers
(2) Location of dispensers with regard to adjacent combustible materials and potential sources of ignition, especially where dispensers are mounted on walls of combustible construction
(3) Requirements for other fire protection features, including complete automatic sprinkler protection, to be installed throughout the compartment
(4) Amount and location of the flammable solutions, both in use and in storage, particularly with respect to potential for leakage or failure of the dispenser

A.18.4.4.1 For example, the provisions of 18.1.1.4.3.1(2) and 18.1.1.4.3.4 do not require the installation of sprinklers if the modification involves less than 50 percent of the area of the smoke compartment and less than 4500 ft^2 (420 m^2) of the area of the smoke compartment.

A.18.5.2.2 For both new and existing buildings, it is the intent to permit the installation and use of fireplace stoves and room heaters utilizing solid fuel as defined in NFPA 211, *Standard for Chimneys, Fireplaces, Vents, and Solid Fuel–Burning Appliances*, provided that all such devices are installed, maintained, and used in accordance with the appropriate provisions of that standard and all manufacturers' specifications. These requirements are not intended to permit freestanding solid fuel–burning appliances such as freestanding wood-burning stoves.

A.18.5.2.3(2)(d) The glass front of a direct-vent fireplace can become extremely hot. Barriers such as screens or mesh installed over the direct-vent glass help reduce the risk of burn from touching the glass.

A.18.5.2.3(2)(e) The intent of locating controls in a restricted location is to ensure staff is aware of use of the fireplace and to prevent unauthorized use. Examples of locked controls are a keyed switch or locating the switch in a staff-controlled location such as a staff station.

A.18.7 Health care occupants have, in large part, varied degrees of physical disability, and their removal to the outside, or even their disturbance caused by moving, is inexpedient or impractical in many cases, except as a last resort. Similarly, recognizing that there might be an operating necessity for the restraint of the mentally ill, often by use of barred windows and locked doors, fire exit drills are usually extremely disturbing, detrimental, and frequently impracticable.

In most cases, fire exit drills, as ordinarily practiced in other occupancies, cannot be conducted in health care occupancies. Fundamentally, superior construction, early discovery and extinguishment of incipient fires, and prompt notification need to be relied on to reduce the occasion for evacuation of buildings of this class to a minimum.

A.18.7.1.4 Many health care occupancies conduct fire drills without disturbing patients by choosing the location of the simulated emergency in advance and by closing the doors to patients' rooms or wards in the vicinity prior to initiation of the drill. The purpose of a fire drill is to test and evaluate the efficiency, knowledge, and response of institutional personnel in implementing the facility fire emergency action plan. Its purpose is not to disturb or excite patients. Fire drills should be scheduled on a random basis to ensure that personnel in health care facilities are drilled not less than once in each 3-month period.

Drills should consider the ability to move patients to an adjacent smoke compartment. Relocation can be practiced using simulated patients or empty wheelchairs.

A.18.7.2.1 Each facility has specific characteristics that vary sufficiently from other facilities to prevent the specification of a universal emergency procedure. The recommendations that follow, however, contain many of the elements that should be considered and adapted, as appropriate, to the individual facility.

Upon discovery of fire, personnel should immediately take the following action:

(1) If any person is involved in the fire, the discoverer should go to the aid of that person, calling aloud an established code phrase, which provides for both the immediate aid of any endangered person and the transmission of an alarm.
(2) Any person in the area, upon hearing the code called aloud, should activate the building fire alarm using the nearest manual fire alarm box.
(3) If a person is not involved in the fire, the discoverer should activate the building fire alarm using the nearest manual fire alarm box.
(4) Personnel, upon hearing the alarm signal, should immediately execute their duties as outlined in the facility fire safety plan.
(5) The telephone operator should determine the location of the fire as indicated by the audible signal.
(6) In a building equipped with an uncoded alarm system, a person on the floor of fire origin should be responsible for promptly notifying the facility telephone operator of the fire location.
(7) If the telephone operator receives a telephone alarm reporting a fire from a floor, the operator should regard that alarm in the same fashion as an alarm received over the fire alarm system and should immediately notify the fire department and alert all facility personnel of the place of fire and its origin.
(8) If the building fire alarm system is out of order, any person discovering a fire should immediately notify the telephone operator by telephone, and the operator should then transmit this information to the fire department and alert the building occupants.

A.18.7.3.3 The purpose of this requirement is to provide a means for building designers, occupants, and operators to clearly designate approved egress corridors that can be identified even though physical or other obvious barriers might not be present to indicate their location. Floor plans used to satisfy this requirement might incorporate more than one function and more than one smoke compartment of the building, provided egress corridors are clearly identified where no fixed barriers are present. Such plans should be accessible to the authority having jurisdiction but should not be required to be posted.

A.18.7.4 The most rigid discipline with regard to prohibition of smoking might not be nearly as effective in reducing incipient fires from surreptitious smoking as the open recognition of smoking, with provision of suitable facilities for smoking. Proper education and training of the staff and attendants in the ordinary fire hazards and their abatement is unquestionably essential. The problem is a broad one, varying with different types and arrangements of buildings; the effectiveness of rules of procedure, which need to be flexible, depends in large part on the management.

A.18.7.5.1 In addition to the provisions of 10.3.1, which deal with ignition resistance, additional requirements with respect to the location of cubicle curtains relative to sprinkler placement are included in NFPA 13, *Standard for the Installation of Sprinkler Systems.*

A.18.7.5.6(2) The user should verify that the products meet the referenced test methods of NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textile and Films,* and not the small-scale test procedure that was previously eliminated from NFPA 701.

A.18.7.5.6(4) The percentage of decorations should be measured against the area of any wall or ceiling, not the aggregate total of walls, ceilings, and doors. The door is considered part of the wall. The decorations must be located such that they do not interfere with the operation of any door, sprinkler, smoke detector, or any other life safety equipment. Other art might include hanging objects or three-dimensional items.

A.18.7.5.7.1(3) It is not the intent to permit collection receptacles with a capacity greater than 32 gal (121 L) to be positioned at or near a nurses' station based on the argument that such nurses' station is constantly attended. The large collection receptacle itself needs to be actively attended by staff. Staff might leave the large receptacle in the corridor outside a patient room while entering the room to collect soiled linen or trash, but staff is expected to return to the receptacle, move on to the next room, and repeat the collection function. Where staff is not actively collecting material for placement in the receptacle, the receptacle is to be moved to a room protected as a hazardous area.

A.18.7.5.7.2 It is the intent that this provision permits recycling of bottles, cans, paper and similar clean items that do not contain grease, oil, flammable liquids, or significant plastic materials using larger containers or several adjacent containers and not require locating such containers in a room protected as a hazardous area. Containers for medical records awaiting shredding are often larger than 32 gal (121 L). These containers are not to be included in the calculations and limitations of 18.7.5.7.1. There is no limit on the number of these containers, as FM Approval Standard 6921, *Containers for Combustible Waste,* ensures that the fire will not spread outside of the container. FM approval standards are written for use with FM Approvals. The tests can be conducted by any approved laboratory. The portions of the standard referring to FM Approvals are not included in this reference.

A.18.7.5.7.2(2) See 18.7.5.7.1(3).

A.18.7.8 Portable space heaters complying with 18.7.8 should be permitted to be located in office areas, nurses stations, and other similar nonpatient spaces within the same smoke compartment as patient sleeping rooms.

A.19.1.1.1.1 In determining equivalency for existing hospitals or nursing homes, the authority having jurisdiction is permitted to accept evaluations based on the health care occupancies fire safety evaluation system (FSES) of NFPA 101A, *Guide on Alternative Approaches to Life Safety*, utilizing the parameters for existing buildings.

A.19.1.1.1.7 There are many reasons why doors in the means of egress in health care occupancies might need to be locked for the protection of the patients or the public. Examples of conditions that might justify door locking include dementia, mental health, infant care, pediatric care, or patients under court detention order requiring medical treatment in a health care facility. See 19.2.2.2.5 for details on door locking.

A.19.1.1.1.10 The *Code* recognizes that certain functions necessary for the life safety of building occupants — such as the detection of fire and associated products of combustion, the closing of corridor doors, the operation of manual fire alarm devices, and the removal of patients from the room of fire origin — require the intervention of facility staff. It is not the intent of 19.1.1.1.10 to specify the levels or locations of staff necessary to meet this requirement.

A.19.1.1.2 This objective is accomplished in the context of the physical facilities, the type of activities undertaken, the provisions for the capabilities of staff, and the needs of all occupants through requirements directed at the following:

(1) Prevention of ignition
(2) Detection of fire
(3) Control of fire development
(4) Confinement of the effects of fire
(5) Extinguishment of fire
(6) Provision of refuge or evacuation facilities, or both
(7) Staff reaction

A.19.1.1.4.3.3 For the purpose of this requirement, a floor that is not divided by a smoke barrier is considered one smoke compartment. Where automatic sprinklers are retrofitted into existing nonsprinklered buildings, the construction alternatives for sprinklers provided in this *Code* are intended to apply to the renovated area.

A.19.1.1.4.3.4 In minor rehabilitation, only the rehabilitation itself is required to be brought up to the requirements for new nonsprinklered facilities, not the entire smoke compartment or building.

A.19.1.3.4 Doctors' offices and treatment and diagnostic facilities that are intended solely for outpatient care and are physically separated from facilities for the treatment or care of inpatients, but that are otherwise associated with the management of an institution, might be classified as business occupancies rather than health care occupancies. Facilities that do not provide housing for patients on a 24-hour basis are required to be classified as other than health care occupancies per 19.1.1.1.9, except where services are provided routinely to four or more inpatients who are incapable of self-preservation.

A.19.1.3.5.1 It is the intent of the *Code* that these requirements apply to mobile, transportable, and relocatable structures (in accordance with 1.3.2) when such structures are used to provide shared medical services on an extended or a temporary basis. Where properly separated from the health care occupancy and intended to provide services simultaneously for three or fewer health care patients who are litterborne, the level of protection for such structures should be based on the appropriate occupancy classification of other chapters of this *Code*. Mobile, transportable, or relocatable structures that are not separated from a contiguous health care occupancy, or that are intended to provide services simultaneously for four or more health care patients who are litterborne, should be classified and designed as health care occupancies.

A.19.1.6.2 Unoccupied space, for the purposes of 19.1.6.2(3), is space not normally occupied by persons, fuel-fired equipment, or hazardous contents.

A.19.2.2.2.4(2) Where delayed-egress locks complying with 7.2.1.6.1 are used, the provisions of 19.2.2.2.5 are not required.

A.19.2.2.2.4(3) Where access-controlled egress doors complying with 7.2.1.6.2 are used, the provisions of 19.2.2.2.5 are not required.

A.19.2.2.2.5.1 Psychiatric units, Alzheimer units, and dementia units are examples of areas with patients who might have clinical needs that justify door locking. Forensic units and detention units are examples of areas with patients who might pose a security threat. Where Alzheimer or dementia patients in nursing homes are not housed in specialized units, the provisions of 19.2.2.2.5.1 should not apply. *(See 19.2.2.2.5.2.)*

A.19.2.2.2.5.2 Pediatric units, maternity units, and emergency departments are examples of areas where patients might have special needs that justify door locking. Door locking arrangements should be permitted to reduce the risk of abduction of infants and children who are patients.

A.19.2.2.2.5.2(3) Where locked doors in accordance with 19.2.2.2.5.2 are proposed for an existing building that is not sprinklered throughout, the authority having jurisdiction might consider permitting the installation based on an analysis of the extent of sprinkler protection provided. Sprinklered areas should include, at a minimum, the secured compartment and compartments that the occupants of the secured compartment must travel through to egress the building.

A.19.2.2.2.7 In some health care occupancies, especially nursing homes, the use of murals to disguise doors has been found to be beneficial for certain patient populations. This provision is intended to apply to disguising of egress doors by painting the doors or the use of wall paper on the doors. The marking of the means of egress such as required exit signs should be clearly visible and not disguised by the mural. Where decorations are applied to the door, the requirements of Section 19.7 would still apply and painting a mural on the door would not be considered a decoration. Such murals should not obscure required vision panels or affect the required fire resistance rating of fire-rated door assemblies.

A.19.2.2.2.7(2) It is intended that the door releasing hardware includes levers, locks, knobs, and panic bars that are directly operated or grasped by staff.

A.19.2.2.2.7(3) It is intended that the door hardware that is permitted to be covered (i.e., disguised by the mural) includes items such as hinges, closers, and magnets, which would normally not be directly operated or grasped by staff.

A.19.2.2.2.8 It is desirable to keep doors in exit passageways, stair enclosures, horizontal exits, smoke barriers, and required enclosures around hazardous areas closed at all times to impede the travel of smoke and fire gases. Functionally, however, this involves decreased efficiency and limits patient supervision by the staff of a facility. To accommodate such needs, it is practical to presume that such doors will be kept open, even to the extent of employing wood chocks and other makeshift devices. Doors in exit passageways, horizontal exits, and smoke barriers should, therefore, be equipped with automatic hold-open devices actuated by the methods described, regardless of whether the original installation of the doors was predicated on a policy of keeping them closed.

A.19.2.2.2.10 Doors to the enclosures of interior stair exits should be arranged to open from the stair side at not less than every third floor so that it will be possible to leave the stairway at such floor if fire renders the lower part of the stair unusable during egress or if occupants seek refuge on another floor.

A.19.2.2.5.3 The waiver of the requirement for doors to swing in the direction of egress travel is based on the assumption that, in this occupancy, there is no possibility of a panic rush that might prevent the opening of doors that swing against egress travel.

A desirable arrangement, which is possible with corridors 8 ft (2440 mm) or more in width, is to have two 42 in. (1070 mm) doors, normally closed, each swinging with the egress travel (in opposite directions).

A.19.2.3.4 It is not the intent that the required corridor width be maintained clear and unobstructed at all times. Projections into the required width are permitted by 7.3.2.2. It is not the intent that 19.2.3.4 supersede 7.3.2.2. Existing corridors more than 48 in. (1220 mm) in width are not permitted to be reduced in width, unless they exceed the width requirements of 18.2.3.4 or 18.2.3.5. *(See 4.6.7.4, 4.6.7.5, and 4.6.12.2.)*

A.19.2.3.4(2) The intent of 19.2.3.4(2) is to permit limited noncontinuous projections along the corridor wall. These include hand-rub dispensing units complying with 19.4.3, nurse charting units, wall-mounted computers, telephones, artwork, bulletin boards, display case frames, cabinet frames, fire alarm boxes, and similar items. It is not the intent to permit the narrowing of the corridor by the walls themselves. The provision of 7.3.2.2 permits projections up to 4½ in. (114 mm) to be present at and below the 38 in. (965 mm) handrail height, and it is not the intent of 19.2.3.4(2) to prohibit such projections.

Building codes and accessibility codes might require cane detection below projections that exceed 4 in. (102 mm).

A.19.2.3.4(4)(c) Wheeled equipment and carts in use include food service carts, housekeeping carts, medication carts, isolation carts, and similar items. Isolation carts should be permitted in the corridor only where patients require isolation precautions.

Unattended wheeled crash carts and other similar wheeled emergency equipment are permitted to be located in the corridor when "not in use," because they need to be immediately accessible during a clinical emergency. Note that "not in use" is not the same as "in storage." Storage is not permitted to be open to the corridor, unless it meets one of the provisions permitted in 19.3.6.1 and is not a hazardous area.

Wheeled portable patient lift or transport equipment needs to be readily available to clinical staff for moving, transferring, toileting, or relocating patients. These devices are used daily for safe handling of patients and to provide for worker safety. This equipment might not be defined as "in use" but needs to be convenient for the use of caregivers at all times.

A.19.2.3.4(5) The means for affixing the furniture can be achieved with removable brackets to allow cleaning and maintenance. Affixing the furniture to the floor or wall prevents the furniture from moving, so as to maintain a minimum 6 ft (1830 mm) corridor clear width. Affixing the furniture to the floor or wall also provides a sturdiness that allows occupants to safely transfer in and out.

A.19.2.3.4(5)(f) Examples of building service and fire protection equipment include fire extinguishers, manual fire alarm boxes, shutoff valves, and similar equipment.

A.19.2.4.4 An exit is not necessary for each individual smoke compartment if there is access to an exit through other smoke compartments without passing through the smoke compartment of fire origin.

A.19.2.5.2 Every exit or exit access should be arranged, if practical and feasible, so that no corridor has a dead end exceeding 30 ft (9.1 m).

A.19.2.5.4 The term *intervening rooms or spaces* means rooms or spaces serving as a part of the required means of egress from another room.

A.19.2.5.6.1 For the purposes of this paragraph, it is the intent that the term *habitable rooms* not include individual bathrooms, closets, and similar spaces, as well as briefly occupied work spaces, such as control rooms in radiology and small storage rooms in a pharmacy.

A.19.2.5.7.1.2 Two or more contiguous suites with an aggregate area not exceeding the suite size limitation of 19.2.5.7.2.3 and 19.2.5.7.3.3 are permitted to be considered a single suite, so as not to require separation from each other. The intent of 19.2.5.7.1.2(2) is to continue to permit suites that have smoke-resisting walls separating them from the rest of the building, even though the walls might not have a fire resistance rating. This requirement includes walls that comply with 19.3.6.2.4, even though sprinkler protection is not provided.

A.19.2.5.7.1.3(A) The term *intervening room* means a room serving as a part of the required means of egress from another room.

A.19.2.5.7.1.3(C) Examples of suites that might be hazardous areas are medical records and pharmaceutical suites.

A.19.2.5.7.1.3(D) It is the intent that the provision of 19.2.5.7.1.3(D) apply only where the quantities of combustibles occupy an area exceeding 50 ft^2 (4.6 m^2) so as to be a hazardous contents area. Where quantities of combustibles occupy less than 50 ft^2 (4.6 m^2), there is no restriction on quantity.

A.19.2.5.7.2.1(B) Supervision of existing sleeping suites is accomplished by direct supervision by staff, automatic smoke detection, or a combination of direct supervision and smoke detection. The following three options are available for meeting the supervision requirements for patient sleeping suites having an area not exceeding 5000 ft^2 (460 m^2):

(1) Direct supervision of all sleeping rooms by staff from a normally attended location within the suite [in accordance with 19.2.5.7.2.1(B)(1)(a)].
(2) Supervision of those sleeping rooms that can be directly supervised [in accordance with 19.2.5.7.2.1(B)(1)(a)] and automatic smoke detection provided in the sleeping rooms that cannot be directly supervised [in accordance with 19.2.5.7.2.1(B)(1)(b)] as depicted in Figure A.19.2.5.7.2.1(B)(a).

(3) Total (complete) coverage automatic smoke detection throughout the sleeping suite [in accordance with 19.2.5.7.2.1(B)(2)] as depicted in Figure A.19.2.5.7.2.1(B)(b).

Where the option for total (complete) coverage automatic smoke detection is used, the provision of 9.6.2.9 requires detectors in all occupiable areas that are suitable for smoke detector operation. For example, an area subject to shower steam would not require a smoke detector.

For patient sleeping suites having an area greater than 5000 ft^2 (460 m^2) but not greater than 7500 ft^2 (700 m^2), sprinkler protection is required throughout the suite and the supervision requirements of 19.2.5.7.2.1 also apply. Such protection might take the form of standard-response sprinklers in accordance with 19.3.5.7 or quick-response sprinklers in accordance with 19.3.5.8. Where standard-response sprinklers are used in accordance with 19.3.5.7, the suite must be protected by total (complete) automatic smoke detection [in accordance with 19.2.5.7.2.3(B)(1)] as depicted in Figure A.19.2.5.7.2.1(B)(c).

For patient sleeping suites having an area greater than 7500 ft^2 (700 m^2), the suite must be protected by quick-response sprinklers in accordance with 19.3.5.8, direct supervision of all sleeping rooms must be provided by staff, and total (complete) coverage automatic smoke detection must be provided throughout the sleeping suite [in accordance with 19.2.5.7.2.3(C)] as depicted in Figure A.19.2.5.7.2.1(B)(d).

A.19.2.5.7.2.1(B)(1) The interior partitions or walls might extend full height to the ceiling, provided that they do not obscure visual supervision of the suite. Where they do obscure visual supervision, see 19.2.5.7.2.1(B)(2).

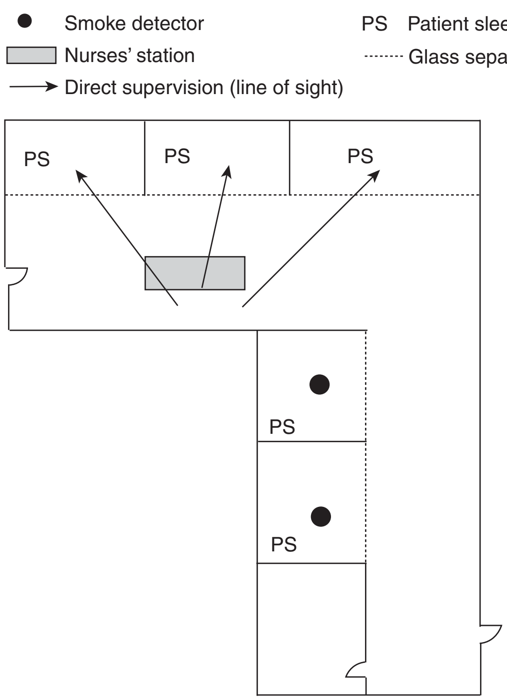

FIGURE A.19.2.5.7.2.1(B)(a) All Sleeping Rooms Provided Either with Direct Supervision by Staff or Smoke Detection.

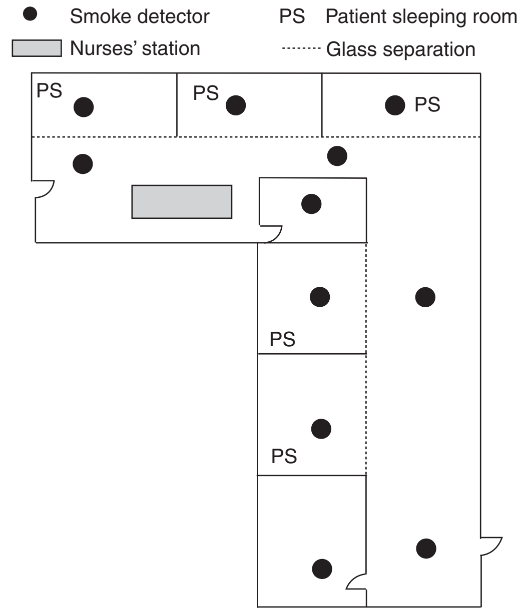

FIGURE A.19.2.5.7.2.1(B)(b) Supervision Provided by Total (Complete) Smoke Detection Throughout the Sleeping Suite.

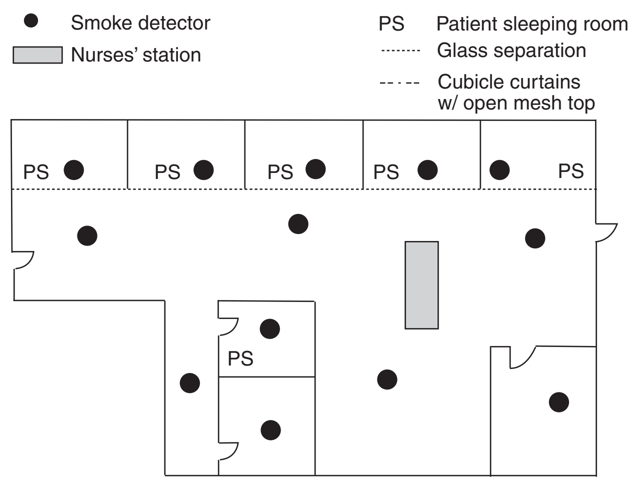

FIGURE A.19.2.5.7.2.1(B)(c) For Suites >5000 ft^2 (>460 m^2) and ≤7500 ft^2 (≤700 m^2) Protected by Standard Response Sprinklers, Total (Complete) Smoke Detection Required Throughout the Sleeping Suite.

A.19.2.5.7.2.2(A) Where only one means of egress is required from the suite, it needs to be provided by a door opening directly to a corridor complying with 19.3.6 or to a horizontal exit.

A.19.2.5.7.2.2(C) Where the second exit access for a sleeping suite is through an adjacent suite, it is the intent that the 100 ft (30 m) travel distance limitation in the suite be applied only to the suite under consideration.

A.19.2.5.7.2.3(C)(1) The alternative of 19.2.5.7.2.1(D)(1)(b) is not to be applied, since 19.2.5.7.2.3 requires total coverage automatic smoke detection for the suite that exceeds 7500 ft^2 (700 m^2) but does not exceed 10,000 ft^2 (930 m^2).

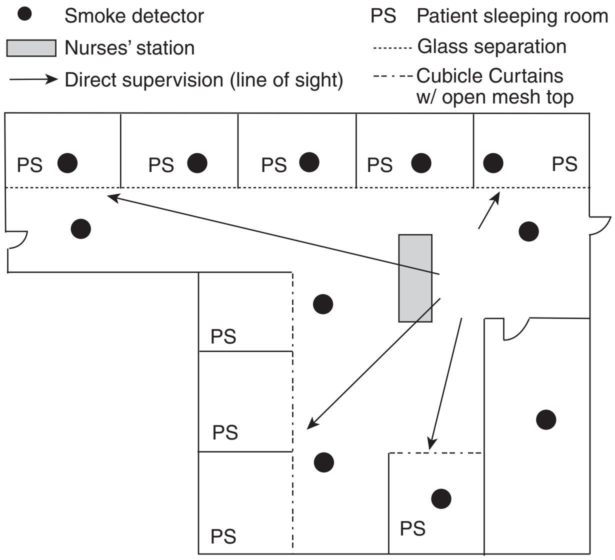

FIGURE A.19.2.5.7.2.1(B)(d) For Suites >7500 ft^2 (>700 m^2), All Sleeping Rooms Must Be Provided with Direct Supervision by Staff and Total (Complete) Smoke Detection Installed Throughout the Sleeping Suite.

A.19.2.5.7.3.1(C) Where the second exit access for a non-sleeping suite is through an adjacent suite, it is the intent that the adjacent suite not be considered an intervening room.

A.19.3.2.1.2 Penetrations of hazardous area walls located above ceilings that comply with Section 8.4 are not required to be sealed to comply with 19.3.2.1.2.

A.19.3.2.5.2 This provision is intended to permit appliances used for reheating, limited cooking, and food preparation, such as microwave ovens, hot plates, electric skillets, toasters, and nourishment centers, tobe exempt from the requirements for commercial cooking equipment and hazardous area protection. Limited quantities of butter, cooking spray, or oil can be used.

A.19.3.2.5.3 The intent of 19.3.2.5.3 is to limit the number of persons for whom meals are routinely prepared to not more than 30. Staff and feeding assistants are not included in this number.

A.19.3.2.5.3(3) The minimum airflow of 500 cfm (14,000 L/m) is intended to require the use of residential hood equipment at the higher end of equipment capacities. It is also intended to draw a sufficient amount of the cooking vapors into the grease baffle and filter system to reduce migration beyond the hood.

A.19.3.2.5.3(6) The intent of this provision is to limit cooking fuel to gas or electricity. The prohibition of solid fuels for cooking is not intended to prohibit charcoal grilling on grills located outside the facility.

A.19.3.2.5.3(9) The intent of this requirement is that the fuel source for the cooktop or range is to be turned on only when staff is present or aware that the kitchen is being used. The timer function is meant to provide an additional safeguard if the staff forgets to deactivate the cooktop or range. If a cooking activity lasts longer than 120 minutes, the timer would be required to be manually reset.

A.19.3.2.5.3(11) Protection of the cooktop or range is accomplished by the sprinklers that are required in the space and the required cooktop hood fire suppression system. The smoke alarms are intended to notify staff who might not be in the immediate area. Smoke alarms should be maintained a minimum of 20 ft (6.1 m) away from the cooktop or range as studies have shown this distance to be the threshold for significantly reducing nuisance alarms caused by cooking. The intent of the interconnected smoke alarms, with silence feature, is that while the devices would alert staff members to a potential problem, if it is a nuisance alarm, the staff members can use the silence feature instead of disabling the alarm. The referenced study indicates that nuisance alarms are reduced with photoelectric smoke alarms. Providing two interconnected alarms provides a safety factor since they are not electrically supervised by the fire alarm system. *(Smoke Alarms – Pilot Study of Nuisance Alarms Associated with Cooking)*

A.19.3.2.5.3(12) The provision of 19.3.2.5.3 recognizes that it is more important to maintain the 20 ft (6.1 m) minimum spacing criterion between the smoke alarm and the cooktop or range, to minimize nuisance alarms, than to assure that the smoke alarm is located within the kitchen area itself.

A.19.3.2.5.3(13) The requirements of 19.3.2.5.3(13) are intended to allow the local staff to silence and reset the system smoke detector without the assistance of the engineering or maintenance personnel. This provision is not intended to require the system smoke detector to initiate a building-wide occupant alarm signal or to notify the emergency forces.

A.19.3.2.5.4 The provisions of 19.3.2.5.4 differ from those of 19.3.2.5.3, as they apply to cooking equipment that is separated from the corridor.

A.19.3.2.5.5 The provision of 19.3.2.5.5 clarifies that protected commercial cooking equipment does not require an enclosure (separation) as a hazardous area in accordance with Section 8.7, as is required by 19.3.2.1.

A.19.3.3.2 The reduction in class of interior finish prescribed by 10.2.8.1 is permitted to be used.

A.19.3.4.2 It is not the intent of this *Code* to require single-station smoke alarms, which might be required by local codes, to be connected to or to initiate the building fire alarm system.

A.19.3.4.3.1(1) It is the intent of this provision to permit a visible fire alarm signal instead of an audible signal to reduce interference between the fire alarm and medical equipment monitoring alarms.

A.19.3.5.4 It is not the intent to require existing standard sprinklers in existing sprinkler systems to be replaced with listed quick-response or listed residential sprinklers. It is the intent that new sprinkler systems installed in existing buildings comply with the requirements of Chapter 18, including 18.3.5.6.

A.19.3.5.7 It is intended that any valve that controls automatic sprinklers in the building or portions of the building, including sectional and floor control valves, be electrically supervised. Valves that control isolated sprinkler heads, such as in laundry and trash chutes, are not required to be electrically supervised. Appropriate means should be provided to ensure that valves that are not electrically supervised remain open.

A.19.3.5.8 The provisions of 19.3.5.8(6) and (7) are not intended to supplant NFPA 13, *Standard for the Installation of Sprinkler Systems*, which requires that residential sprinklers with more than a 10°F (5.6°C) difference in temperature rating not be mixed within a room. Currently there are no additional prohibitions in NFPA 13 on the mixing of sprinklers having different thermal response characteristics. Conversely, there are no design parameters to make practical the mixing of residential and other types of sprinklers.

Residential sprinklers are considered acceptable in patient sleeping rooms of all health care facilities, even though not specifically listed for this purpose in all cases.

A.19.3.5.8(6) It is not the intent of the *Code* to permit standard-response sprinklers to meet the criteria of 19.3.5.8 just because the sprinklers were installed before quick-response sprinklers were invented or listed. The intent of 19.3.5.8(6) is to permit older quick-response systems to be credited, even though there might be some standard-response sprinklers in existence due to the fact that quick-response sprinklers were unavailable for those specific locations at the time. For example, in the early days of quick-response sprinklers, there were no high-temperature quick-response sprinklers available.

A.19.3.5.10 This exception is limited to hospitals, as nursing homes and many limited care facilities might have more combustibles within the closets. The limited amount of clothing found in the small clothes closets in hospital patient rooms is typically far less than the amount of combustibles in casework cabinets that do not require sprinkler protection, such as nurse servers. In many hospitals, especially new hospitals, it is difficult to make a distinction between clothes closets and cabinet work. The exception is far more restrictive than similar exceptions for hotels and apartment buildings. NFPA 13, *Standard for the Installation of Sprinkler Systems,* already permits the omission of sprinklers in wardrobes [see 8.1.1(7) of NFPA 13]. It is not the intent of 19.3.5.10 to affect the wardrobe provisions of NFPA 13. It is the intent that the sprinkler protection in the room covers the closet as if there were no door on the closet. *(See 8.5.3.2.3 of NFPA 13.)*

A.19.3.5.11 For the proper operation of sprinkler systems, cubicle curtains and sprinkler locations need to be coordinated. Improperly designed systems might obstruct the sprinkler spray from reaching the fire or might shield the heat from the sprinkler. Many options are available to the designer including, but not limited to, hanging the cubicle curtains 18 in. (455 mm) below the sprinkler deflector; using ½ in. (13 mm) diagonal mesh or a 70 percent open weave top panel that extends 18 in. (455 mm) below the sprinkler deflector; or designing the system to have a horizontal and minimum vertical distance that meets the requirements of NFPA 13, *Standard for the Installation of Sprinkler Systems.* The test data that forms the basis of the NFPA 13 requirements is from fire tests with sprinkler discharge that penetrated a single privacy curtain.

A.19.3.6.1(1)(a) The presence of stored combustible materials in a room or space open to the corridor does not necessarily result in the room or space being classified as a hazardous area. In some circumstances, the amount and type of combustibles might result in the room or space being classified as a hazardous area by the authority having jurisdiction.

A.19.3.6.1(3) A typical nurses' station would normally contain one or more of the following with associated furniture and furnishings:

(1) Charting area
(2) Clerical area
(3) Nourishment station
(4) Storage of small amounts of medications, medical equipment and supplies, clerical supplies, and linens
(5) Patient monitoring and communication equipment

A.19.3.6.1(7)(b) A fully developed fire (flashover) occurs if the rate of heat release of the burning materials exceeds the capability of the space to absorb or vent that heat. The ability of common lining (wall, ceiling, and floor) materials to absorb heat is approximately 0.75 Btu/ft^2 (0.07 kJ/m^2) of lining. The venting capability of open doors or windows is in excess of 20 Btu/ft^2 (1.95 kJ/m^2) of opening. In a fire that has not reached flashover conditions, fire will spread from one furniture item to another only if the burning item is close to another furniture item. For example, if individual furniture items have a heat release rate of 500 Btu/s (525 kW) and are separated by 12 in. (305 mm) or more, the fire is not expected to spread from item to item, and flashover is unlikely to occur. *(See also the NFPA Fire Protection Handbook.)*

A.19.3.6.1(8) This provision permits waiting areas to be located across the corridor from each other, provided that neither area exceeds the 600 ft^2 (55.7 m^2) limitation.

A.19.3.6.2.2 The intent of the minimum ½-hour fire resistance rating for corridor partitions is to require a nominal fire rating, particularly where the fire rating of existing partitions cannot be documented. Examples of acceptable partition assemblies would include, but are not limited to, ½ in. (13 mm) gypsum board, wood lath and plaster, gypsum lath, or metal lath and plaster.

A.19.3.6.2.3 The purpose of extending a corridor wall above a lay-in ceiling or through a concealed space is to provide a barrier to limit the passage of smoke. Such a barrier is not required to be either a smoke barrier or a smoke partition — two terms for which specific *Code* definitions and requirements apply. The intent of 19.3.6.2.3 is not to require light-tight barriers above lay-in ceilings or to require an absolute seal of the room from the corridor. Small holes, penetrations, or gaps around items such as ductwork, conduit, or telecommunication lines should not affect the ability of this barrier to limit the passage of smoke.

A.19.3.6.2.4 An architectural, exposed, suspended-grid acoustical tile ceiling with penetrating items, such as sprinkler piping and sprinklers; ducted HVAC supply and return-air diffusers; speakers; and recessed lighting fixtures, is capable of limiting the transfer of smoke.

A.19.3.6.2.6 Monolithic ceilings are continuous horizontal membranes composed of noncombustible or limited-combustible materials, such as plaster or gypsum board, with seams or cracks permanently sealed.

A.19.3.6.3 The provision of 19.3.6.3 requires the door leaves to be of substantial construction that is sufficient to resist fire for 20 minutes. These doors, described as 1¾ in. (44 mm) thick, solid-bonded wood-core doors, are nonrated doors and are not subject to the requirements of NFPA 80, *Standard for Fire Doors and Other Opening Protectives.*

A.19.3.6.3.1 Gasketing of doors should not be necessary to achieve resistance to the passage of smoke if the door is relatively tight-fitting.

A.19.3.6.3.5 While it is recognized that closed doors serve to maintain tenable conditions in a corridor and adjacent patient rooms, such doors, which, under normal or fire conditions, are self-closing, might create a special hazard for the personal safety of a room occupant. Such closed doors might present a problem of delay in discovery, confining fire products beyond tenable conditions.

Because it is critical for responding staff members to be able to immediately identify the specific room involved, it is recommended that approved automatic smoke detection that is interconnected with the building fire alarm be considered for rooms having doors equipped with closing devices. Such detection is permitted to be located at any approved point within the room. When activated, the detector is required to provide a warning that indicates the specific room of involvement by activation of a fire alarm annunciator, nurse call system, or any other device acceptable to the authority having jurisdiction.

In existing buildings, use of the following options reasonably ensures that patient room doors will be closed and remain closed during a fire:

(1) Doors should have positive latches, and a suitable program that trains staff to close the doors in an emergency should be established.
(2) It is the intent of the *Code* that no new installations of roller latches be permitted; however, repair or replacement of roller latches is not considered a new installation.
(3) Doors protecting openings to patient sleeping or treatment rooms, or spaces having a similar combustible loading, might be held closed using a closer exerting a closing force of not less than 5 lbf (22 N) on the door latch stile.

A.19.3.6.3.10 Doors should not be blocked open by furniture, door stops, chocks, tie-backs, drop-down or plunger-type devices, or other devices that necessitate manual unlatching or releasing action to close. Examples of hold-open devices that release when the door is pushed or pulled are friction catches or magnetic catches.

A.19.3.6.3.12 It is not the intent of 19.3.6.3.12 to prohibit the application of push plates, hardware, or other attachments on corridor doors in health care occupancies.

A.19.3.6.5.1 It is not the intent of 19.3.6.5.1 to permit mail slots or pass-through openings in doors or walls of rooms designated as a hazardous area.

A.19.3.7.3(2) Where the smoke control system design requires dampers in order that the system functions effectively, it is not the intent of the exception to permit the damper to be omitted.

This provision is not intended to prevent the use of plenum returns where ducting is used to return air from a ceiling plenum through smoke barrier walls. Short stubs or jumper ducts are not acceptable. Ducting is required to connect at both sides of the opening and to extend into adjacent spaces away from the wall. The intent is to prohibit open-air transfers at or near the smoke barrier walls.

A.19.3.7.6.1 It is not the intent of 19.3.7.6.1 to prohibit the application of push plates, hardware, or other attachments on smoke barrier doors in health care occupancies.

A.19.3.7.8 Smoke barriers might include walls having door openings other than cross-corridor doors. There is no restriction in the *Code* regarding which doors or how many doors form part of a smoke barrier. For example, doors from the corridor to individual rooms are permitted to form part of a smoke barrier.

A.19.4.2.2 The provision of 19.4.2.2 is intended to prevent the phase-in period for the installation of sprinklers from being reset to 12 years upon adoption of the 2015 edition of the *Code* in jurisdictions where the 12-year period had already begun via the adoption of the 2012 edition.

A.19.4.2.3 The provision of 19.4.2.3 is intended to prevent the phase-in period for the installation of sprinklers from being reset to 12 years upon adoption of the 2015 edition of the *Code* in jurisdictions where the 12-year period had already begun via the adoption of the 2009 edition.

A.19.4.3 Extensive research, including fire modeling, has indicated that alcohol-based hand-rub solutions can be safely installed in corridors of health care facilities, provided that certain other precautions are taken. The total quantities of flammable liquids in any area should comply with the provisions of other recognized codes, including NFPA 1, *Fire Code*, and NFPA 30, *Flammable and Combustible Liquids Code*. In addition, special consideration should be given to the following:

(1) Obstructions created by the installation of hand-rub solution dispensers
(2) Location of dispensers with regard to adjacent combustible materials and potential sources of ignition, especially where dispensers are mounted on walls of combustible construction
(3) Requirements for other fire protection features, including complete automatic sprinkler protection, to be installed throughout the compartment
(4) Amount and location of the flammable solutions, both in use and in storage, particularly with respect to potential for leakage or failure of the dispenser

A.19.5.2.2 For both new and existing buildings, it is the intent to permit the installation and use of fireplace stoves and room heaters using solid fuel as defined in NFPA 211, *Standard for Chimneys, Fireplaces, Vents, and Solid Fuel–Burning Appliances*, provided that all such devices are installed, maintained, and used in accordance with the appropriate provisions of that standard and all manufacturers' specifications. These requirements are not intended to permit freestanding solid fuel–burning appliances such as freestanding wood-burning stoves.

A.19.5.2.3(2)(d) The glass front of a direct-vent fireplace can become extremely hot. Barriers such as screens or mesh installed over the direct-vent glass help reduce the risk of burn from touching the glass.

A.19.5.2.3(2)(e) The intent of locating controls in a restricted location is to ensure staff is aware of use of the fireplace and to prevent unauthorized use. Examples of locked controls are a keyed switch or locating the switch in a staff-controlled location such as a staff station.

A.19.7 Health care occupants have, in large part, varied degrees of physical disability, and their removal to the outside, or even their disturbance caused by moving, is inexpedient or impractical in many cases, except as a last resort. Similarly, recognizing that there might be an operating necessity for the restraint of the mentally ill, often by use of barred windows and locked doors, fire exit drills are usually extremely disturbing, detrimental, and frequently impracticable.

In most cases, fire exit drills, as ordinarily practiced in other occupancies, cannot be conducted in health care occupancies. Fundamentally, superior construction, early discovery and extinguishment of incipient fires, and prompt notification need to be relied on to reduce the occasion for evacuation of buildings of this class to a minimum.

A.19.7.1.4 Many health care occupancies conduct fire drills without disturbing patients by choosing the location of the simulated emergency in advance and by closing the doors to patients' rooms or wards in the vicinity prior to initiation of the drill. The purpose of a fire drill is to test and evaluate the efficiency, knowledge, and response of institutional personnel in implementing the facility fire emergency action plan. Its purpose is not to disturb or excite patients. Fire drills should be scheduled on a random basis to ensure that personnel in health care facilities are drilled not less than once in each 3-month period.

Drills should consider the ability to move patients to an adjacent smoke compartment. Relocation can be practiced using simulated patients or empty wheelchairs.

A.19.7.2.1 Each facility has specific characteristics that vary sufficiently from other facilities to prevent the specification of a universal emergency procedure. The recommendations that follow, however, contain many of the elements that should be considered and adapted, as appropriate, to the individual facility.

Upon discovery of fire, personnel should immediately take the following action:

(1) If any person is involved in the fire, the discoverer should go to the aid of that person, calling aloud an established code phrase, which provides for both the immediate aid of any endangered person and the transmission of an alarm.
(2) Any person in the area, upon hearing the code called aloud, should activate the building fire alarm using the nearest manual fire alarm box.
(3) If a person is not involved in the fire, the discoverer should activate the building fire alarm using the nearest manual fire alarm box.
(4) Personnel, upon hearing the alarm signal, should immediately execute their duties as outlined in the facility fire safety plan.
(5) The telephone operator should determine the location of the fire as indicated by the audible signal.
(6) In a building equipped with an uncoded alarm system, a person on the floor of fire origin should be responsible for promptly notifying the facility telephone operator of the fire location.
(7) If the telephone operator receives a telephone alarm reporting a fire from a floor, the operator should regard that alarm in the same fashion as an alarm received over the fire alarm system and should immediately notify the fire department and alert all facility personnel of the place of fire and its origin.
(8) If the building fire alarm system is out of order, any person discovering a fire should immediately notify the telephone operator by telephone, and the operator should then transmit this information to the fire department and alert the building occupants.

A.19.7.3.3 The purpose of this requirement is to provide a means for building designers, occupants, and operators to clearly designate approved egress corridors that can be identified even though physical or other obvious barriers might not be present to indicate their location. Floor plans used to satisfy this requirement might incorporate more than one function and more than one smoke compartment of the building, provided egress corridors are clearly identified where no fixed barriers are present. Such plans should be accessible to the authority having jurisdiction but should not be required to be posted.

A.19.7.4 The most rigid discipline with regard to prohibition of smoking might not be nearly as effective in reducing incipient fires from surreptitious smoking as the open recognition of smoking, with provision of suitable facilities for smoking. Proper education and training of the staff and attendants in the ordinary fire hazards and their abatement is unquestionably essential. The problem is a broad one, varying with different types and arrangements of buildings; the effectiveness of rules of procedure, which need to be flexible, depends in large part on the management.

A.19.7.5.1 In addition to the provisions of 10.3.1, which deal with ignition resistance, additional requirements with respect to the location of cubicle curtains relative to sprinkler placement are included in NFPA 13, *Standard for the Installation of Sprinkler Systems*.

A.19.7.5.6(2) The user should verify that the products meet the referenced test methods of NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films*, and not the small-scale test procedure that was previously eliminated from NFPA 701.

A.19.7.5.6(4) The percentage of decorations should be measured against the area of any wall or ceiling, not the aggregate total of walls, ceilings, and doors. The door is considered part of the wall. The decorations must be located such that they do not interfere with the operation of any door, sprinkler, smoke detector, or any other life safety equipment. Other art might include hanging objects or three-dimensional items.

A.19.7.5.6(5) When determining if the hazard for fire development or spread is present, consideration should be given to whether the building or area being evaluated is sprinklered.

A.19.7.5.7.1(3) It is not the intent to permit collection receptacles with a capacity greater than 32 gal (121 L) to be positioned at or near a nurses' station based on the argument that such nurses' station is constantly attended. The large collection receptacle itself needs to be actively attended by staff. Staff might leave the large receptacle in the corridor outside a patient room while entering the room to collect soiled linen or trash, but staff is expected to return to the receptacle, move on to the next room, and repeat the collection function. Where staff is not actively collecting material for placement in the receptacle, the receptacle is to be moved to a room protected as a hazardous area.

A.19.7.5.7.2 It is the intent that this provision permits recycling of bottles, cans, paper, and similar clean items that do not contain grease, oil, flammable liquids, or significant plastic materials, using larger containers or several adjacent containers, and not require locating such containers in a room protected as a hazardous area. Containers for medical records awaiting shredding are often larger than 32 gal (121 L). These containers are not to be included in the calculations and limitations of 19.7.5.7.1. There is no limit on the number of these containers, as FM Approval Standard 6921, *Containers for Combustible Waste*, ensures that the fire will not spread outside of the container. FM approval standards are written for use with FM Approvals. The tests can be conducted by any approved laboratory. The portions of the standard referring to FM Approvals are not included in this reference.

A.19.7.5.7.2(2) See 19.7.5.7.1(3).

A.19.7.7 A document that provides recognized engineering principles for the testing of smoke control systems is NFPA 92, *Standard for Smoke Control Systems*.

A.19.7.8 Portable space heaters complying with 19.7.8 should be permitted to be located in office areas, nurses stations, and other similar nonpatient spaces within the same smoke compartment as patient sleeping rooms.

A.20.1.1.1.6 The *Code* recognizes that certain functions necessary for the life safety of building occupants, such as the closing of corridor doors, the operation of manual fire alarm devices, and the removal of patients from the room of fire origin, require the intervention of facility staff. It is not the intent of 20.1.1.1.6 to specify the levels or locations of staff necessary to meet this requirement.

A.20.1.1.2 This objective is accomplished in the context of the physical facilities, the type of activities undertaken, the provisions for the capabilities of staff, and the needs of all occupants through requirements directed at the following:

(1) Prevention of ignition
(2) Detection of fire
(3) Control of fire development
(4) Confinement of the effects of fire
(5) Extinguishment of fire
(6) Provision of refuge or evacuation facilities, or both
(7) Staff reaction

A.20.1.3.2 Doctors' offices and treatment and diagnostic facilities that are intended solely for outpatient care and are physically separated from facilities for the treatment or care of inpatients, but are otherwise associated with the management of an institution, might be classified as business occupancies rather than health care occupancies.

A.20.2.2.2.4 The words "principal entrance/exit doors" describe doors that the authority having jurisdiction can reasonably expect to be unlocked in order for the facility to do business.

A.20.2.3.3 Building codes and accessibility codes might require cane detection below projections that exceed 4 in. (102 mm).

A.20.3.2.1 It is not the intent of this provision that rooms inside individual tenant spaces that are used to store routine office supplies for that tenant be required to be either separated or sprinklered.

A.20.3.2.3 The requirement for separating high-hazard contents areas from other parts of the building is intended to isolate the hazard, and 8.2.3.3 is applicable.

A.20.3.6.1 The intent of 38.3.6(1) through (3) is to permit spaces to be open to the exit access corridor without separation.

A.20.3.6.1(1) Where exits are available from an open floor area, such as open plan buildings, corridors are not required to be separated. An example of an open plan building is a building in which the work spaces and accesses to exits are delineated by the use of tables, desks, bookcases, or counters, or by partitions that are less than floor-to-ceiling height.

A.20.3.6.1(2) It is the intent of this provision that a single tenant be limited to an area occupied under a single management and work the same hours. The concept is that people under the same employ working the same hours would likely be familiar with their entire tenant space. It is not the intent to apply this provision simply because tenants are owned by the same organization. For example, in a government-owned office building, the offices of different federal agencies would be considered multiple tenants, because an employee normally works for one agency. The agencies might work various hours. Another example of multiple tenancy would be a classroom building of a university, because some classrooms might be in use at times when other classrooms are not being used.

A.20.3.7.10 Smoke barriers might include walls having door openings other than cross-corridor doors. There is no restriction in the *Code* regarding which doors or how many doors form part of a smoke barrier. For example, doors from the corridor to individual rooms are permitted to form part of a smoke barrier.

A.20.3.7.14 Split astragals (i.e., astragals installed on both door leaves) are also considered astragals.

A.20.4.3 Extensive research, including fire modeling, has indicated that alcohol-based hand-rub solutions can be safely installed in corridors of health care facilities, provided that certain other precautions are taken. The total quantities of flammable liquids in any area should comply with the provisions of other recognized codes, including NFPA 1, *Fire Code*, and NFPA 30, *Flammable and Combustible Liquids Code*. In addition, special consideration should be given to the following:

(1) Obstructions created by the installation of hand-rub solution dispensers
(2) Location of dispensers with regard to adjacent combustible materials and potential sources of ignition, especially where dispensers are mounted on walls of combustible construction
(3) Requirements for other fire protection features, including complete automatic sprinkler protection, to be installed throughout the compartment
(4) Amount and location of the flammable solutions, both in use and in storage, particularly with respect to potential for leakage or failure of the dispenser

A.20.7 Ambulatory health care occupants have, in large part, varied degrees of physical disability, and their removal to the outside, or even their disturbance caused by moving, is inexpedient or impractical in many cases, except as a last resort. Similarly, recognizing that there might be an operating necessity for the restraint of the mentally ill, often by use of barred windows and locked doors, fire exit drills are usually extremely disturbing, detrimental, and frequently impracticable.

In most cases, fire exit drills, as ordinarily practiced in other occupancies, cannot be conducted in ambulatory health care occupancies. Fundamentally, superior construction, early discovery and extinguishment of incipient fires, and prompt notification need to be relied on to reduce the occasion for evacuation of buildings of this class to a minimum.

A.20.7.1.4 Many ambulatory health care occupancies conduct fire drills without disturbing patients by choosing the location of the simulated emergency in advance and by closing the doors in the vicinity prior to the initiation of the drill. The purpose of a fire drill is to test and evaluate the efficiency, knowledge, and response of personnel in implementing the facility fire emergency plan. Its purpose is not to disturb or excite patients. Fire drills should be scheduled on a random basis to ensure that personnel in ambulatory health care facilities are drilled not less than once in each 3-month period.

Drills should consider the ability to move patients to an adjacent smoke compartment. Relocation can be practiced using simulated patients or empty wheelchairs.

A.20.7.2.1 Each facility has specific characteristics that vary sufficiently from other facilities to prevent the specification of a universal emergency procedure. The recommendations that follow, however, contain many of the elements that should be considered and adapted, as appropriate, to the individual facility.

Upon discovery of fire, personnel should immediately take the following action:

(1) If any person is involved in the fire, the discoverer should go to the aid of that person, calling aloud an established code phrase, which provides for both the immediate aid of any endangered person and the transmission of an alarm.
(2) Any person in the area, upon hearing the code called aloud, should activate the building fire alarm using the nearest manual fire alarm box.
(3) If a person is not involved in the fire, the discoverer should activate the building fire alarm using the nearest manual fire alarm box.
(4) Personnel, upon hearing the alarm signal, should immediately execute their duties as outlined in the facility fire safety plan.
(5) The telephone operator should determine the location of the fire as indicated by the audible signal.
(6) In a building equipped with an uncoded alarm system, a person on the floor of fire origin should be responsible for promptly notifying the facility telephone operator of the fire location.
(7) If the telephone operator receives a telephone alarm reporting a fire from a floor, the operator should regard that alarm in the same fashion as an alarm received over the fire alarm system and should immediately notify the fire department and alert all facility personnel of the place of fire and its origin.
(8) If the building fire alarm system is out of order, any person discovering a fire should immediately notify the telephone operator by telephone, and the operator should then transmit this information to the fire department and alert the building occupants.

A.20.7.4 The most rigid discipline with regard to prohibition of smoking might not be nearly as effective in reducing incipient fires from surreptitious smoking as the open recognition of smoking, with provision of suitable facilities for smoking. Proper education and training of the staff and attendants in the ordinary fire hazards and their abatement is unquestionably essential. The problem is a broad one, varying with different types and arrangements of buildings; the effectiveness of rules of procedure, which need to be flexible, depends in large part on the management.

A.20.7.5.1 In addition to the provisions of 10.3.1, which deal with ignition resistance, additional requirements with respect to the location of cubicle curtains relative to sprinkler placement are included in NFPA 13, *Standard for the Installation of Sprinkler Systems.*

A.20.7.5.4(4) The percentage of decorations should be measured against the area of any wall or ceiling, not the aggregate total of walls, ceilings, and doors. The door is considered part of the wall. The decorations must be located such that they do not interfere with the operation of any door, sprinkler, smoke detector, or any other life safety equipment. Other art might include hanging objects or three-dimensional items.

A.20.7.5.5.2 It is the intent that this provision permits recycling of bottles, cans, paper, and similar clean items that do not contain grease, oil, flammable liquids, or significant plastic materials using larger containers or several adjacent containers and not require locating such containers in a room protected as a hazardous area. Containers for medical records awaiting shredding are often larger than 32 gal (121 L). These containers are not to be included in the calculations and limitations of 20.7.5.5.1. There is no limit on the number of these containers, as FM Approval Standard 6921, *Containers for Combustible Waste,* ensures that the fire will not spread outside of the container. FM approval standards are written for use with FM Approvals. The tests can be conducted by any approved laboratory. The portions of the standard referring to FM Approvals are not included in this reference.

A.20.7.5.5.2(2) See 20.7.5.5.1(3).

A.20.7.7 A document that provides recognized engineering principles for the testing of smoke control systems is NFPA 92, *Standard for Smoke Control Systems.*

A.21.1.1.1.6 The *Code* recognizes that certain functions necessary for the life safety of building occupants, such as the closing of corridor doors, the operation of manual fire alarm devices, and the removal of patients from the room of fire origin, require the intervention of facility staff. It is not the intent of 21.1.1.1.6 to specify the levels or locations of staff necessary to meet this requirement.

A.21.1.1.2 This objective is accomplished in the context of the physical facilities, the type of activities undertaken, the provisions for the capabilities of staff, and the needs of all occupants through requirements directed at the following:

(1) Prevention of ignition
(2) Detection of fire
(3) Control of fire development
(4) Confinement of the effects of fire
(5) Extinguishment of fire
(6) Provision of refuge or evacuation facilities, or both
(7) Staff reaction

A.21.1.3.3 Doctors' offices and treatment and diagnostic facilities that are intended solely for outpatient care and are physically separated from facilities for the treatment or care of inpatients, but that are otherwise associated with the management of an institution, might be classified as business occupancies rather than health care occupancies.

A.21.2.2.2.4 The words "principal entrance/exit doors" describe doors that the authority having jurisdiction can reasonably expect to be unlocked in order for the facility to do business.

A.21.2.2.2.12 The waiver of the requirement for doors to swing in the direction of egress travel is based on the assumption that, in this occupancy, there is little possibility of a panic rush that might prevent the opening of doors that swing against egress travel.

A desirable arrangement, which is possible with corridors 6 ft (1830 mm) or more in width, is to have two 32 in. (810 mm) doors, normally closed, each swinging with the egress travel (in opposite directions).

A.21.2.3.3 Building codes and accessibility codes might require cane detection below projections that exceed 4 in. (102 mm).

A.21.3.2.1 It is not the intent of this provision that rooms inside individual tenant spaces that are used to store routine office supplies for that tenant be required to be either separated or sprinklered.

A.21.3.2.3 The requirement for separating high-hazard contents areas from other parts of the building is intended to isolate the hazard, and 8.2.3.3 is applicable.

A.21.3.7.10 Smoke barriers might include walls having door openings other than cross-corridor doors. There is no restriction in the *Code* regarding which doors or how many doors form part of a smoke barrier. For example, doors from the corridor to individual rooms are permitted to form part of a smoke barrier.

A.21.4.2.2 In some cases, appreciable cost might be involved in bringing an existing occupancy into compliance. Where this is true, it would be appropriate for the authority having jurisdiction to prescribe a schedule determined jointly with the facility, allowing suitable periods of time for the correction of the various deficiencies and giving due weight to the ability of the owner to secure the necessary funds.

A.21.4.3 Extensive research, including fire modeling, has indicated that alcohol-based hand-rub solutions can be safely installed in corridors of health care facilities, provided that certain other precautions are taken. The total quantities of flammable liquids in any area should comply with the provisions of other recognized codes, including NFPA 1, *Fire Code*, and NFPA 30, *Flammable and Combustible Liquids Code*. In addition, special consideration should be given to the following:

(1) Obstructions created by the installation of hand-rub solution dispensers
(2) Location of dispensers with regard to adjacent combustible materials and potential sources of ignition, especially where dispensers are mounted on walls of combustible construction
(3) Requirements for other fire protection features, including complete automatic sprinkler protection, to be installed throughout the compartment
(4) Amount and location of the flammable solutions, both in use and in storage, particularly with respect to potential for leakage or failure of the dispenser

A.21.7 Ambulatory health care occupants have, in large part, varied degrees of physical disability, and their removal to the outside, or even their disturbance caused by moving, is inexpedient or impractical in many cases, except as a last resort. Similarly, recognizing that there might be an operating necessity for the restraint of the mentally ill, often by use of barred windows and locked doors, fire exit drills are usually extremely disturbing, detrimental, and frequently impracticable.

In most cases, fire exit drills, as ordinarily practiced in other occupancies, cannot be conducted in ambulatory health care occupancies. Fundamentally, superior construction, early discovery and extinguishment of incipient fires, and prompt notification need to be relied on to reduce the occasion for evacuation of buildings of this class to a minimum.

A.21.7.1.4 Many ambulatory health care occupancies conduct fire drills without disturbing patients by choosing the location of the simulated emergency in advance and by closing the doors in the vicinity prior to initiation of the drill. The purpose of a fire drill is to test and evaluate the efficiency, knowledge, and response of personnel in implementing the facility fire emergency plan. Its purpose is not to disturb or excite patients. Fire drills should be scheduled on a random basis to ensure that personnel in ambulatory health care facilities are drilled not less than once in each 3-month period.

Drills should consider the ability to move patients to an adjacent smoke compartment. Relocation can be practiced using simulated patients or empty wheelchairs.

A.21.7.2.1 Each facility has specific characteristics that vary sufficiently from other facilities to prevent the specification of a universal emergency procedure. The recommendations that follow, however, contain many of the elements that should be considered and adapted, as appropriate, to the individual facility.

Upon discovery of fire, personnel should immediately take the following action:

(1) If any person is involved in the fire, the discoverer should go to the aid of that person, calling aloud an established code phrase, which provides for both the immediate aid of any endangered person and the transmission of an alarm.
(2) Any person in the area, upon hearing the code called aloud, should activate the building fire alarm using the nearest manual fire alarm box.
(3) If a person is not involved in the fire, the discoverer should activate the building fire alarm using the nearest manual fire alarm box.
(4) Personnel, upon hearing the alarm signal, should immediately execute their duties as outlined in the facility fire safety plan.
(5) The telephone operator should determine the location of the fire as indicated by the audible signal.
(6) In a building equipped with an uncoded alarm system, a person on the floor of fire origin should be responsible for promptly notifying the facility telephone operator of the fire location.
(7) If the telephone operator receives a telephone alarm reporting a fire from a floor, the operator should regard that alarm in the same fashion as an alarm received over the fire alarm system and should immediately notify the fire department and alert all facility personnel of the place of fire and its origin.
(8) If the building fire alarm system is out of order, any person discovering a fire should immediately notify the telephone operator by telephone, and the operator should then transmit this information to the fire department and alert the building occupants.

A.21.7.4 The most rigid discipline with regard to prohibition of smoking might not be nearly as effective in reducing incipient fires from surreptitious smoking as the open recognition of smoking, with provision of suitable facilities for smoking. Proper education and training of the staff and attendants in the ordinary fire hazards and their abatement is unquestionably essential. The problem is a broad one, varying with different types and arrangements of buildings; the effectiveness of rules of procedure, which need to be flexible, depends in large part on the management.

A.21.7.5.1 In addition to the provisions of 10.3.1, which deal with ignition resistance, additional requirements with respect to the location of cubicle curtains relative to sprinkler placement are included in NFPA 13, *Standard for the Installation of Sprinkler Systems*.

A.21.7.5.4(4) The percentage of decorations should be measured against the area of any wall or ceiling, not the aggregate total of walls, ceilings, and doors. The door is considered part of the wall. The decorations must be located such that they do not interfere with the operation of any door, sprinkler, smoke detector, or any other life safety equipment. Other art might include hanging objects or three-dimensional items.

A.21.7.5.5.2 It is the intent that this provision permits recycling of bottles, cans, paper, and similar clean items that do not contain grease, oil, flammable liquids, or significant plastic materials using larger containers or several adjacent containers and not require locating such containers in a room protected as a hazardous area. Containers for medical records awaiting shredding are often larger than 32 gal (121 L). These containers are not to be included in the calculations and limitations of 21.7.5.5.1. There is no limit on the number of these containers, as FM Approval Standard 6921, *Containers for Combustible Waste,* ensures that the fire will not spread outside of the container. FM approval standards are written for use with FM Approvals. The tests can be conducted by any approved laboratory. The portions of the standard referring to FM Approvals are not included in this reference.

A.21.7.5.5.2(2) See 21.7.5.5.1(3).

A.21.7.7 A document that provides recognized engineering principles for the testing of smoke control systems is NFPA 92, *Standard for Smoke Control Systems.*

A.22.1.1.1.4(2) In determining equivalency for conversions, modernizations, renovations, or unusual design concepts of detention and correctional facilities, the authority having jurisdiction is permitted to accept evaluations based on the detention and correctional occupancies fire safety evaluation system (FSES) of NFPA 101A, *Guide on Alternative Approaches to Life Safety*, utilizing the parameters for new construction.

A.22.1.1.1.6 It is not the intent to classify as detention and correctional occupancies the areas of health care occupancies in which doors are locked against patient egress where needed for the clinical needs of the patients. For example, a dementia treatment center can be adequately protected by the health care occupancies requirements of Chapter 18. *[See 18.1.1.1.7, 18.2.2.2.2, 18.2.2.2.4(1), and 18.2.2.2.6.]*

The one-resident threshold requirement of 22.1.1.1.6 is not meant to force a residential occupancy, where security is imposed on one or more occupants, to be reclassified as a detention and correctional occupancy.

A.22.1.1.1.7 Lockups in which persons are detained with some degree of security imposed on them are common in many occupancies. Examples include the following:

(1) Immigration and naturalization facilities at border crossings
(2) Customs facilities at international airports
(3) Prisoner holding facilities at courthouses
(4) Local police department holding areas
(5) Security offices at sports stadia
(6) Security offices at shopping mall complexes

A.22.1.2.1 Users and occupants of detention and correctional facilities at various times can be expected to include staff, visitors, and residents. The extent and nature of facility utilization vary according to the type of facility, its function, and its programs.

Figure A.22.1.2.1 illustrates the five use conditions.

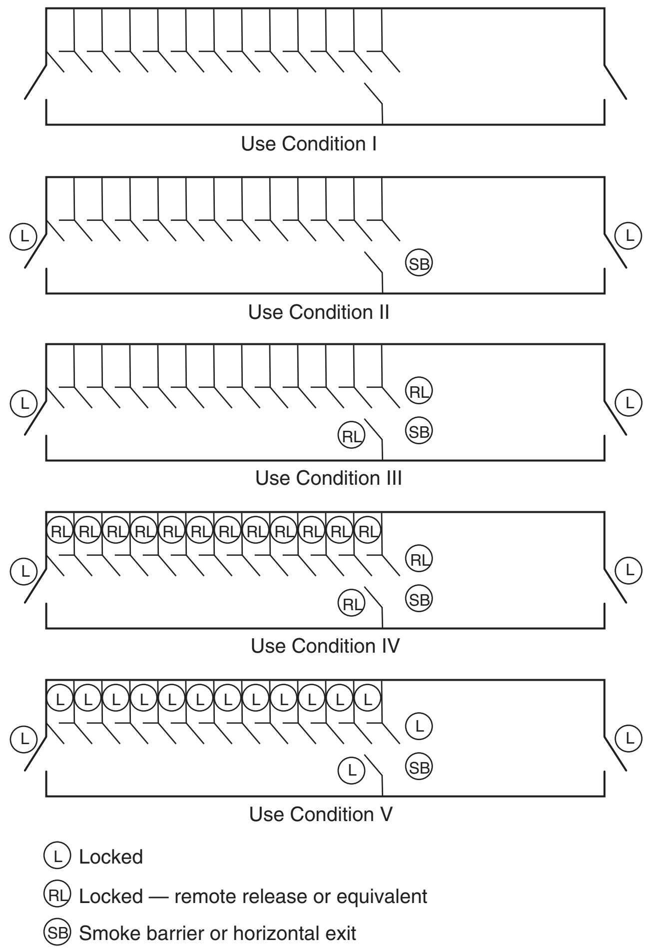

FIGURE A.22.1.2.1 Detention and Correctional Use Conditions.

A.22.1.2.2 Prompt operation is intended to be accomplished in the period of time between detection of fire, either by the smoke detector(s) required by 22.3.4.4 or by other means, whichever occurs first, and the advent of intolerable conditions forcing emergency evacuation. Fire tests have indicated that the time available is a function of the volume and height of the space involved and the rate of fire development. In traditional one-story corridor arrangements, the time between detection by smoke detectors and the advent of lethal conditions down to head height can be as short as approximately 3 minutes. In addition, it should be expected that approximately 1 minute will be required to evacuate all the occupants of a threatened smoke compartment once the locks are released. In such a case, a prompt release time would be 2 minutes.

A.22.1.2.3(2) If the Use Condition I facility conforms to the requirements of residential occupancies under this *Code*, there are no staffing requirements. If the Use Condition I facility conforms to the requirements of Use Condition II facilities as permitted by this provision, staffing is required in accordance with 22.7.1.

A.22.1.3 Detention and correctional facilities are a complex of structures, each serving a definite and usually different purpose. In many institutions, all, or almost all, the occupancy-type classifications found in this *Code* are represented. Means of egress and other features are governed by the type of occupancy classification and the hazard of occupancy, unless specific exemptions are made.

All buildings and structures are to be classified using Chapter 22 and Section 6.1 as a guide, subject to the ruling of the authority having jurisdiction where a question arises concerning the proper classification of any individual building or structure.

Use condition classification of the institution, as well as of individual areas within the complex, is always to be considered by the authority having jurisdiction.

A.22.1.3.2.2 Key-operated locking hardware of a lesser grade than institutional grade hardware might not be suitable for the heavy use to which such locks are expected to be subjected.

A.22.2.2.5.2 An exit is not necessary from each individual fire compartment or smoke compartment if there is access to an exit through other fire compartments or smoke compartments without passing through the fire compartment or smoke compartment of fire origin.

A.22.2.11.4 It might be necessary to provide a certain number of resident sleeping rooms with doors providing a clear width of not less than 32 in. (810 mm) *(see 7.2.1.2)* in order to comply with the requirements for the physically handicapped. Such sleeping rooms should be located where there is a direct accessible route to the exterior or to an area of safe refuge. *(See 22.3.7.)*

A.22.2.11.8 A remote position is generally a control point where a number of doors can be unlocked simultaneously, either mechanically or electrically. In areas where there are a number of sleeping rooms, it is impractical for attendants to unlock doors individually. Doors in an exit should be unlocked prior to unlocking sleeping room doors. Sight and sound supervision of resident living areas can be by means of camera and communications systems.

This section of the *Code* does not intend to prohibit Use Condition V facilities, nor does it intend to limit Use Condition V facilities to 10 manually released locks.

A.22.3.1(2) For purposes of providing control valves and waterflow devices, multilevel residential housing areas complying with this provision are considered to be one story.

A.22.3.2.1 Combustible loading in any room opening onto a residential housing area should be limited to reduce the potential for room flashover. Rooms in which fuel loads are not controlled, thereby creating a potential for flashover, should be considered hazardous areas. Where fire-rated separation is provided, doors to such rooms, including sleeping rooms, should be self-closing.

It is strongly recommended that padded cells not be used due to their fire record. However, recognizing that they will be used in some cases, provisions for the protection of padded cells are provided. It is recognized that the minimum ¾-hour fire protection–rated fire door will be violated with the "plant on" of the padding, but a minimum ¾-hour fire protection–rated fire door should be the base of the assembly.

A.22.3.4.3.1(2) The staff at the constantly attended location should have the capability to promptly initiate the general alarm function and contact the fire department or have direct communication with a control room or other location that can initiate the general alarm function and contact the fire department.

A.22.3.4.4 Examples of contiguous common spaces are galleries and corridors.

A.22.3.4.4.3 An open dormitory is a dormitory that is arranged to allow staff to observe the entire dormitory area at one time.

A.22.3.5.4(1) Where access to portable fire extinguishers is locked, staff should be present on a 24-hour basis and should have keys readily available to unlock access to the extinguishers. Where supervision of sleeping areas is from a 24-hour attended staff location, portable fire extinguishers are permitted to be provided at the staff location in lieu of the sleeping area.

A.22.3.5.4(2) It is recognized that locating portable fire extinguishers only at staff locations might result in travel distances to extinguishers being in excess of those permitted by NFPA 10, *Standard for Portable Fire Extinguishers*.

A.22.3.7.1(2) A door to the outside, by itself, does not meet the intent of this provision if emergency operating procedures do not provide for the door to be unlocked when needed. In cases where use of the door is not ensured, a true smoke barrier per the base requirement of 22.3.7.1 would be needed.

A.22.3.7.5 Structural fire resistance is defined as the ability of the assembly to stay in place and maintain structural integrity without consideration of heat transmission. Twelve-gauge steel plate suitably framed and stiffened meets this requirement.

A.22.3.7.6(1) As an example, a smoke barrier is permitted to consist of fire-rated glazing panels mounted in a security grille arrangement.

A.22.3.8 The requirements in Table 22.3.8 for smoke-resistant separations include taking the necessary precautions to restrict the spread of smoke through the air-handling system. However, the intent is not that smoke dampers are required to be provided for each opening. Smoke dampers would be one acceptable method; however, other techniques, such as allowing the fans to continue to run with 100 percent supply and 100 percent exhaust, would be acceptable.

A.22.4.4.3 This provision is intended to promote the use of horizontal exits in detention and correctional occupancies. Horizontal exits provide an especially effective egress system for an occupancy in which the occupants, due to security concerns, are not commonly released to the outside. This provision offers a *Code*-specified equivalent alternative to the requirement of 7.2.4.3.5 that horizontal exits are not to be penetrated by ducts in nonsprinklered buildings. The intended continuity of the fire resistance–rated and smoke-resisting barrier is maintained by requiring that duct penetrations of horizontal exits be protected by combination fire damper/smoke leakage–rated dampers that will close upon activation of a smoke detector and a heat-actuated mechanism before the barrier's ability to resist the passage of smoke and fire is compromised.

A.22.4.4.6.2 It is not the intent of this requirement to restrict room face separations, which restrict visibility from the common space into individual sleeping rooms.

A.22.4.4.6.4 The vertical separation between the lowest floor level and the uppermost floor level is not to exceed 13 ft (3960 mm). Figure A.22.4.4.6.4 illustrates how the height is to be determined.

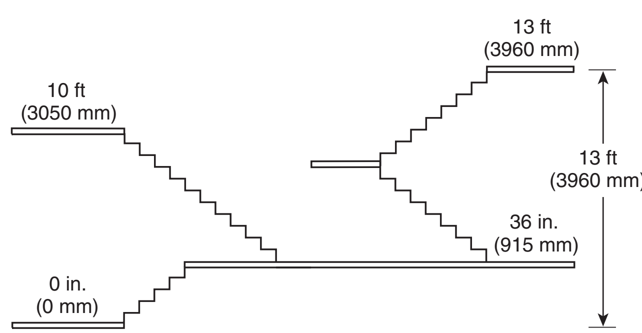

FIGURE A.22.4.4.6.4 Vertical Height Measurement.

A.22.4.4.11 The requirements in Table 22.4.4.11 for smoke-resistant and fire-rated separations include taking the necessary precautions to restrict the spread of smoke through the air-handling system. However, the intent is that smoke dampers are required to be provided for each opening. Smoke dampers would be one acceptable method; however, other techniques, such as allowing the fans to continue to run with 100 percent supply and 100 percent exhaust, would be acceptable.

A.22.4.4.12.2(2) The automatic smoke venting should be in accordance with NFPA 204, *Standard for Smoke and Heat Venting*, for light hazard occupancies.

A.22.4.4.13.2 Mattresses used in detention and correctional facilities should be evaluated with regard to the fire hazards of the environment. The potential for vandalism and excessive wear and tear also should be taken into account when evaluating the fire performance of the mattress. ASTM F 1870, *Standard Guide for Selection of Fire Test Methods for the Assessment of Upholstered Furnishings in Detention and Correctional Facilities*, provides guidance for this purpose.

A.22.4.5.1.4(1) The term *other physical restraints* is meant to include the use of personal restraint devices, such as handcuffs or shackles, where occupants are secured to the structure or furnishings to restrict movement.

A.22.4.6 The health, security, and fire safety implications should be reviewed by the detention and correction facility prior to installation.

A.22.7.1.2 This requirement is permitted to be met by electronic or oral monitoring systems, visual monitoring, call signals, or other means.

A.22.7.1.3 Periodic, coordinated training should be conducted and should involve detention and correctional facility personnel and personnel of the fire department legally committed to serving the facility.

A.22.7.2 Personal property provides combustible contents for fire development. Therefore, adequate controls are needed to limit the quantity and combustibility of the fuels available to burn to reduce the probability of room flashover. The provisions of 22.7.4 will not, by themselves, prevent room flashover if personal property controls are not provided.

A.22.7.4 The type, quantity, and arrangement of furniture and other combustibles are important factors in determining how fast the fire will develop. Furnishings, including upholstered items and wood items, such as wardrobes, desks, and bookshelves, might provide sufficient fuel to result in room flashover, which is the full fire involvement of all combustibles within a room once sufficient heat has been built up within the room.

A.23.1.1.1.4(2) In determining equivalency for existing detention and correctional facilities, the authority having jurisdiction is permitted to accept evaluations based on the detention and correctional occupancies fire safety evaluation system (FSES) of NFPA 101A, *Guide on Alternative Approaches to Life Safety*, utilizing the parameters for existing buildings.

A.23.1.1.1.6 It is not the intent to classify as detention and correctional occupancies the areas of health care occupancies in which doors are locked against patient egress where needed for the clinical needs of the patients. For example, a dementia treatment center can be adequately protected by the health care occupancies requirements of Chapter 19. *[See 19.1.1.1.7, 19.2.2.2.2, 19.2.2.2.4(1), and 19.2.2.2.6.]*

The one-resident threshold requirement of 23.1.1.1.6 is not meant to force a residential occupancy, where security is imposed on one or more occupants, to be reclassified as a detention and correctional occupancy.

A.23.1.1.1.7 Lockups in which persons are detained with some degree of security imposed on them are common in many occupancies. Examples include the following:

(1) Immigration and naturalization facilities at border crossings
(2) Customs facilities at international airports
(3) Prisoner holding facilities at courthouses
(4) Local police department holding areas
(5) Security offices at sports stadia
(6) Security offices at shopping mall complexes

A.23.1.2.1 Users and occupants of detention and correctional facilities at various times can be expected to include staff, visitors, and residents. The extent and nature of facility utilization will vary according to the type of facility, its function, and its programs.

Figure A.23.1.2.1 illustrates the five use conditions.

A.23.1.2.2 Prompt operation is intended to be accomplished in the period of time between detection of fire, either by the smoke detector(s) required by 23.3.4.4 or by other means, whichever

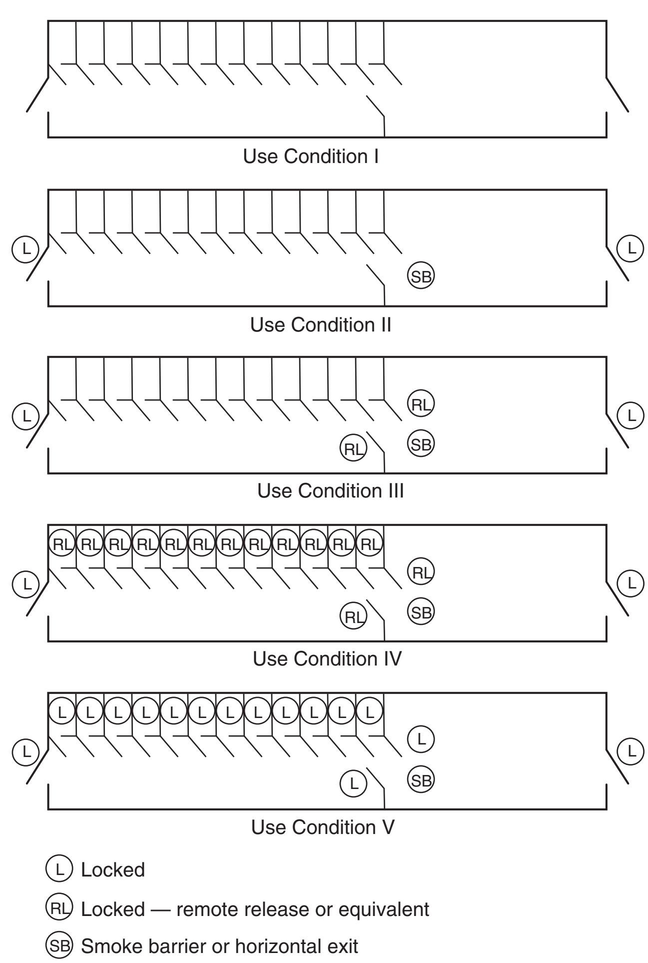

FIGURE A.23.1.2.1 Detention and Correctional Use Conditions.

occurs first, and the advent of intolerable conditions forcing emergency evacuation. Fire tests have indicated that the time available is a function of the volume and height of the space involved and the rate of fire development. In traditional one-story corridor arrangements, the time between detection by smoke detectors and the advent of lethal conditions down to head height can be as short as approximately 3 minutes. In addition, it should be expected that approximately 1 minute will be required to evacuate all the occupants of a threatened smoke compartment once the locks are released. In such a case, a prompt release time would be 2 minutes.

A.23.1.2.3(2) If the Use Condition I facility conforms to the requirements of residential occupancies under this *Code*, there are no staffing requirements. If the Use Condition I facility conforms to the requirements of Use Condition II facilities as permitted by this exception, staffing is required in accordance with 23.7.1.

A.23.1.3 Detention and correctional facilities are a complex of structures, each serving a definite and usually different purpose. In many institutions, all, or almost all, of the occupancy-type classifications found in this *Code* are represented. Means of egress and other features are governed by the type of occupancy classification and the hazard of occupancy, unless specific exemptions are made.

All buildings and structures are to be classified using Chapter 23 and Section 6.1 as a guide, subject to the ruling of the authority having jurisdiction where there is a question as to the proper classification of any individual building or structure.

Use condition classification of the institution, as well as of individual areas within the complex, is always to be considered by the authority having jurisdiction.

A.23.1.3.2.1 Key-operated locking hardware should be of institutional grade. Lesser grade hardware might not be suitable for the heavy use to which such locks are expected to be subjected.

A.23.2.2.5.2 An exit is not necessary from each individual fire compartment if there is access to an exit through other fire compartments without passing through the fire compartment of fire origin.

A.23.2.2.5.3 This provision is intended to promote the use of horizontal exits in detention and correctional occupancies. Horizontal exits provide an especially effective egress system for an occupancy in which the occupants, due to security concerns, are not commonly released to the outside. This provision offers a *Code*-specified equivalent alternative to the requirement of 7.2.4.3.5 that horizontal exits are not to be penetrated by ducts. The intended continuity of the fire resistance–rated and smoke-resisting barrier is maintained by requiring that duct penetrations of horizontal exits be protected by combination fire damper/smoke leakage–rated dampers that close upon activation of a smoke detector and a heat-actuated mechanism before the barrier's ability to resist the passage of smoke and fire is compromised.

A.23.2.4.2 Multilevel and multitiered residential housing areas meeting the requirements of 23.3.1.2 and 23.3.1.3 are considered one story. Therefore, two exits are not required from each level; only access to two exits is required.

A.23.2.4.3 An exit is not necessary from each individual fire compartment and smoke compartment if there is access to an exit through other fire compartments or smoke compartments without passing through the fire compartment or smoke compartment of fire origin.

A.23.2.5.2 Every exit or exit access should be arranged, if feasible, so that no corridor or aisle has a pocket or dead end exceeding 50 ft (15 m) for Use Conditions II, III, and IV and 20 ft (6100 mm) for Use Condition V.

A.23.2.5.3(3) In determining whether to approve the existing common path of travel that exceeds 50 ft (15 m), the authority having jurisdiction should ensure that the common path is not in excess of the travel distance permitted by 23.2.6.

A.23.2.11.4 It might be necessary to provide a certain number of resident sleeping rooms with doors providing a clear width of not less than 32 in. (810 mm) *(see 7.2.1.2)* in order to comply with the requirements for the physically handicapped. Such sleeping rooms should be located where there is a direct accessible route to the exterior or to an area of safe refuge. *(See 23.3.7.)*

A.23.2.11.8 A remote position is generally a control point where a number of doors can be unlocked simultaneously, either mechanically or electrically. In areas where there are a number of sleeping rooms, it is impractical for attendants to unlock doors individually. Doors in an exit should be unlocked prior to unlocking sleeping room doors. Sight and sound supervision of resident living areas can be by means of camera and communications systems.

This section of the *Code* does not intend to prohibit Use Condition V facilities, nor does it intend to limit Use Condition V facilities to 10 manually released locks.

A.23.3.1.2.1 It is not the intent of this requirement to restrict room face separations, which restrict visibility from the common space into individual sleeping rooms.

A.23.3.1.2.3 The vertical separation between the lowest floor level and the uppermost floor level is not to exceed 13 ft (3960 mm). Figure A.23.3.1.2.3 illustrates how the height is to be determined.

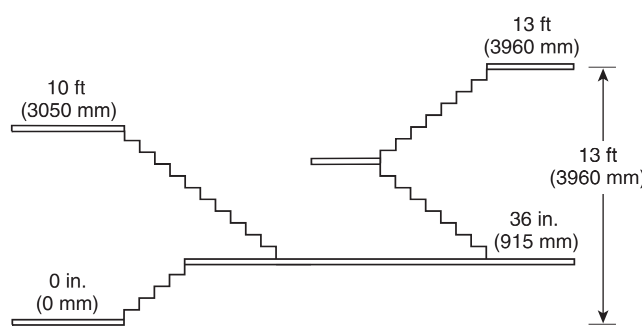

FIGURE A.23.3.1.2.3 Vertical Height Measurement.

A.23.3.1.3 A recommended method of calculating the expected level of smoke in a smoke removal–equipped cell block follows.

This method for calculating the expected level of smoke has been developed from data experimentally produced in full-scale burnouts of test cells. The test cells were sized, loaded with fuel, and constructed to represent severe conditions of heavily fuel-loaded [approximately 6 lb/ft^2 (29 kg/m^2)] cells as found in prison locations. The filling rate and temperature of the effluent gas and smoke have been calculated using the data from these tests and established formulae from plume dynamics.

The application of the method described in A.23.3.1.3 should be limited to situations where there is not less than 10 ft (3050 mm) from the floor level to the lowest acceptable level of smoke accumulation *(Z)*; the reservoir above the lowest acceptable level for *Z* is at least 20 percent of the *Z* dimension; the length of the cell block is not less than *Z*; and the fan is not less than 10 ft (3050 mm) higher than the floor of the highest cell.

The determination of smoke removal requirements is based on the dimensions of the cell opening. Where more than one cell opening is involved, the larger size on the level being calculated should be used.

The fan size, temperature rating, and operations means can be determined by the procedure that follows.

Acceptable Smoke Level. Determine the lowest acceptable level of smoke accumulation in accordance with 23.3.1.3. The vertical distance between that level and the floor level of the lowest open cell is the value of *Z* to be used in connection with Figure A.23.3.1.3(a).

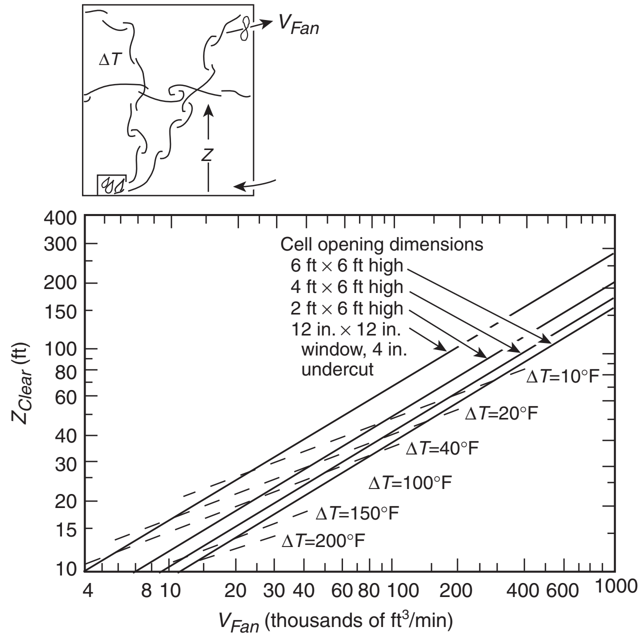
Characteristic Cell Opening. Determine the opening of the cell face. Where there is more than one size of cell opening, use the largest. Match the actual opening to those shown in Figure A.23.3.1.3(b), and use the corresponding curve from Figure A.23.3.1.3(a). If there is no match between the size and shape of the opening and Figure A.23.3.1.3(a), interpolate between the curves. If the opening exceeds 6 ft × 6 ft (1.8 m × 1.8 m), use the curve for a 6 ft × 6 ft (1.8 m × 1.8 m) opening. This curve represents the maximum burning situation, and increasing the size of the opening will not increase the actual burning rate.

Exhaust Fan Rate. Determine the exhaust fan capacity needed to extract smoke at a rate that will maintain the smoke level at a point higher than *Z*. This is the rate shown on the baseline of Figure A.23.3.1.3(a) corresponding to the level of *Z* on the vertical axis for the solid line (ventilation rate) curve appropriate to the cell door size. This exhaust capability needs to be provided at a point higher than *Z*.

Intake Air. Provide intake air openings that either exist or are automatically provided at times of emergency smoke removal. These openings are to be located at or near the baseline of the cell block to allow for intake air at the rate to be vented by the fan. The openings provided shall be sufficient to avoid a friction load that can reduce the exhaust efficiency. Standard air-handling design criteria are used in making this calculation.

Fan Temperature Rating. Determine the potential temperature of gases that the fan might be required to handle by measuring the distance from the floor of the highest cell to the centerline of the fan, or fan ports if the fan is in a duct or similar arrangement. Determine the intersection of the new *Z* value with the appropriate ventilation rate curve (solid line) from Figure A.23.3.1.3(a). Estimate the temperature rise by interpolating along the appropriate ventilation rate curve and between the constant temperature rise curves (dashed lines) from Figure A.23.3.1.3(a). Provide all elements of the exhaust system that are to be above the acceptable smoke level with the capability to effectively operate with the indicated increase in temperature.

Operation of Exhaust System. Arrange the emergency exhaust system to initiate automatically on detection of smoke, on operation of a manual fire alarm system, or by direct manual operation. The capability to manually start the automatic exhaust system should be provided in a guard post in the cell block, at another control location, or both. Where appropriate, the emergency exhaust fans are permitted to be used for comfort ventilation as well as for serving their emergency purposes.



For SI units, 1 ft = 0.3048 m; 1 in. = 25.4 mm; (°F −32) ÷ 1.8 = °C; 1 ft^3/min = 0.00047 m^3/s

ΔT = Temperature of upper layer gases above ambient
Z_{Clear} = Distance from cell floor to smoke layer
V_{Fan} = Fan discharge capacity (as installed)

Solid lines: Ventilation rate curves
Dashed lines: Constant temperature rise curves

FIGURE A.23.3.1.3(a) Cell Block Smoke Control Ventilation Curves.

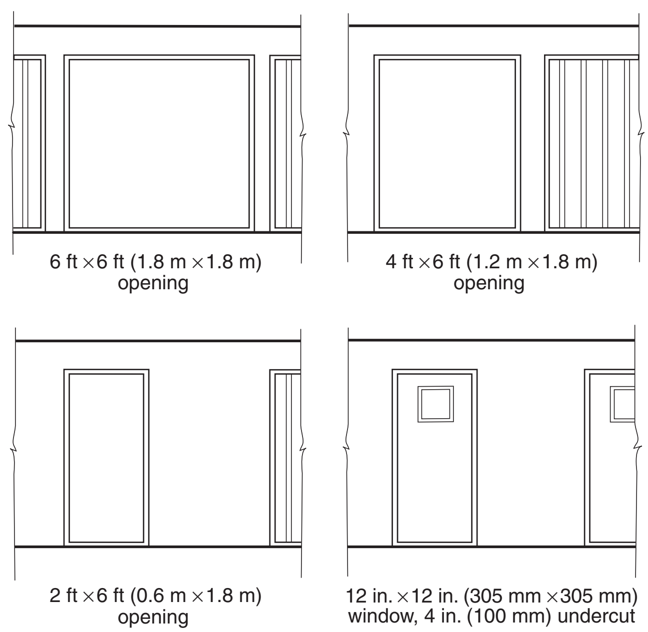


FIGURE A.23.3.1.3(b) Typical Cell Openings.

A.23.3.2.1 It is strongly recommended that padded cells not be used due to their fire record. However, recognizing that they will be used in some cases, provisions for the protection of padded cells are provided. It is recognized that the minimum ¾-hour fire protection–rated fire door will be violated with the "plant on" of the padding, but a minimum ¾-hour fire protection–rated fire door should be the base of the assembly.

A.23.3.4.3.1(2) The staff at the constantly attended location should have the capability to promptly initiate the general alarm function and contact the fire department or have direct communication with a control room or other location that can initiate the general alarm function and contact the fire department.

A.23.3.4.4.3 An open dormitory is a dormitory that is arranged to allow staff to observe the entire dormitory area at one time.

A.23.3.5.2 Where the openings in ceilings or partitions are ¼ in. (6.3 mm) or larger in the smallest dimension, where the thickness or depth of the material does not exceed the smallest dimension of the openings, and where such openings constitute not less than 70 percent of the area of the ceiling or partition material, the disruption of sprinkler spray patterns is permitted to be disregarded.

A.23.3.5.4(1) Where access to portable fire extinguishers is locked, staff should be present on a 24-hour basis and should have keys readily available to unlock access to the extinguishers. Where supervision of sleeping areas is from a 24-hour attended staff location, portable fire extinguishers are permitted to be provided at the staff location in lieu of the sleeping area.

A.23.3.5.4(2) It is recognized that locating portable fire extinguishers only at staff locations might result in travel distances to extinguishers being in excess of those permitted by NFPA 10, *Standard for Portable Fire Extinguishers*.

A.23.3.7.1 Consideration can be given for large open areas that might be permitted to function as smoke sinks as an alternative to the installation of more than one smoke barrier as required by 23.3.7.1. Vertical movement downward to an area of refuge might be permitted by the authority having jurisdiction in lieu of horizontal movement.

A.23.3.7.1(2) A door to the outside, by itself, does not meet the intent of this provision if emergency operating procedures do not provide for the door to be unlocked when needed. In cases where use of the door is not ensured, a true smoke barrier per the base requirement of 23.3.7.1 would be needed.

A.23.3.7.3(2) Consideration should be given to increasing the travel distance to a smoke barrier to coincide with existing range lengths and exits.

A.23.3.7.5 Structural fire resistance is defined as the ability of the assembly to stay in place and maintain structural integrity without consideration of heat transmission. Twelve-gauge steel plate suitably framed and stiffened meets this requirement.

A.23.3.7.6(1) As an example, a smoke barrier is permitted to consist of fire-rated glazing panels mounted in a security grille arrangement.

A.23.3.8 The requirements in Table 23.3.8 or smoke-resistant and fire-rated separations include taking the necessary precautions to restrict the spread of smoke through the air-handling system. However, the intent is not that smoke dampers are required to be provided for each opening. Smoke dampers would be one acceptable method; however, other techniques, such as allowing the fans to continue to run with 100 percent supply and 100 percent exhaust, would be acceptable.

A.23.4.1.2(2) The automatic smoke venting should be in accordance with NFPA 204, *Standard for Smoke and Heat Venting*, for light hazard occupancies.

A.23.4.5.1.4(1) The term *other physical restraints* is meant to include the use of personal restraint devices, such as handcuffs or shackles, where occupants are secured to the structure or furnishings to restrict movement.

A.23.4.6 The health, security, and fire safety implications should be reviewed by the detention and correction facility prior to installation.

A.23.7.1.2 This requirement is permitted to be met by electronic or oral monitoring systems, visual monitoring, call signals, or other means.

A.23.7.1.3 Periodic, coordinated training should be conducted and should involve detention and correctional facility personnel and personnel of the fire department legally committed to serving the facility.

A.23.7.2 Personal property provides combustible contents for fire development. Therefore, adequate controls are needed to limit the quantity and combustibility of the fuels available to burn to reduce the probability of room flashover. The provisions of 23.7.4 will not, by themselves, prevent room flashover if personal property controls are not provided.

A.23.7.4.3 Mattresses used in detention and correctional facilities should be evaluated with regard to the fire hazards of the environment. The potential for vandalism and excessive wear and tear also should be taken into account when evaluating the fire performance of the mattress. ASTM F 1870, *Standard Guide for Selection of Fire Test Methods for the Assessment of Upholstered Furnishings in Detention and Correctional Facilities*, provides guidance for this purpose.

A.24.1.1.2 The *Code* specifies that, wherever there are three or more living units in a building, the building is considered an apartment building and is required to comply with either Chapter 30 or Chapter 31, as appropriate. A townhouse unit is considered to be an apartment building if there are three or more units in the building. The type of wall required between units in order to consider them as separate buildings is normally established by the authority having jurisdiction. If the units are separated by a wall of sufficient fire resistance and structural integrity to be considered as separate buildings, the provisions of Chapter 24 apply to each townhouse. Condominium status is a form of ownership, not occupancy; for example, there are condominium warehouses, condominium apartments, and condominium offices.

The provisions of 24.1.1.2 state that, in one- and two-family dwellings, each dwelling unit can be "occupied by members of a single family with not more than three outsiders." The *Code* does not define the term *family*. The definition of *family* is subject to federal, state, and local regulations and might not be restricted to a person or a couple (two people) and their children. The following examples aid in differentiating between a single-family dwelling and a lodging or rooming house:

(1) An individual or a couple (two people) who rent a house from a landlord and then sublease space for up to three individuals should be considered a family renting to a maximum of three outsiders, and the house should be regulated as a single-family dwelling in accordance with Chapter 24.

(2) A house rented from a landlord by an individual or a couple (two people) in which space is subleased to 4 or more individuals, but not more than 16, should be considered and regulated as a lodging or rooming house in accordance with Chapter 26.
(3) A residential building that is occupied by 4 or more individuals, but not more than 16, each renting from a landlord, without separate cooking facilities, should be considered and regulated as a lodging or rooming house in accordance with Chapter 26.

A.24.2 The phrase "means of escape" indicates a way out of a residential unit that does not conform to the strict definition of means of egress but does meet the intent of the definition by providing an alternative way out of a building. *(See the definition of means of escape in 3.3.172.)*

A.24.2.2.3.3 A window with dimensions of 20 in. × 24 in. (510 mm × 610 mm) has an opening of 3.3 ft^2 (0.31 m^2), which is less than the required 5.7 ft^2 (0.53 m^2). Therefore, either the height or width needs to exceed the minimum requirement to provide the required clear area *(see Figure A.24.2.2.3.3.* The current minimum width and height dimensions, as well as the minimum clear opening, became a requirement of this *Code* in the 1976 edition and were based on tests conducted to determine the minimum size of the wall opening required to allow a fire fighter wearing complete turnout gear and a self-contained breathing apparatus entry to the room from the exterior to effect search and rescue. Prior editions of the *Code* limited the width or height, or both, to not less than 22 in. (560 mm) and a clear opening of 5 ft^2 (0.47 m^2). For existing window frames and sash of steel construction, adherence to these dimensional criteria is essential to allow fire fighter entry. For existing window frames and sash of wood construction that can easily be removed prior to entry by fire fighters to achieve the 5 ft^2 (0.47 m^2) hole in the wall, the clear opening created by the occupant upon opening the window from the interior room side is required only to provide an opening measuring not less than 20 in. × 24 in. (510 mm × 610 mm) or 3.3 ft^2 (0.31 m^2).

A.24.2.4.7 It is the intent of this requirement that security measures, where installed, do not prevent egress.

A.24.3.4.1.1 Paragraph 11.5.1.3 of *NFPA 72, National Fire Alarm and Signaling Code*, contains related requirements. They specify that, where the interior floor area for a given level of a dwelling unit, excluding garage areas, is greater than 1000 ft^2 (93 m^2), smoke alarms are to be installed as follows:

(1) All points on the ceiling are to have a smoke alarm within a distance of 30 ft (9.1 m), measured along a path of travel, or to have one smoke alarm per 500 ft^2 (46.5 m^2) of floor area, which is calculated by dividing the total interior floor area per level by 500 ft^2 (46.5 m^2).
(2) Where dwelling units include great rooms or vaulted/cathedral ceilings extending over multiple floors, smoke alarms located on the upper floor that are intended to protect the aforementioned area are permitted to be considered as part of the lower floor(s) protection scheme used to meet the requirements of A.24.3.4.1.1(1).

A.24.3.4.1.1(2) Paragraphs 11.5.1.1(2) and 11.5.1.2 of *NFPA 72, National Fire Alarm and Signaling Code*, contain related requirements. The requirement of 11.5.1.1(2) specifies that an alarm is to be installed outside of each separate dwelling unit sleeping area, within 21 ft (6.4 m) of any door to a sleeping room, with the distance measured along a path of travel. The requirement in 11.5.1.2 specifies that, where the area addressed in 11.5.1.1(2) is separated from the adjacent living areas by a door, a smoke alarm is to be installed in the area between the door and the sleeping rooms, and additional alarms are to be installed on the living area side of the door.

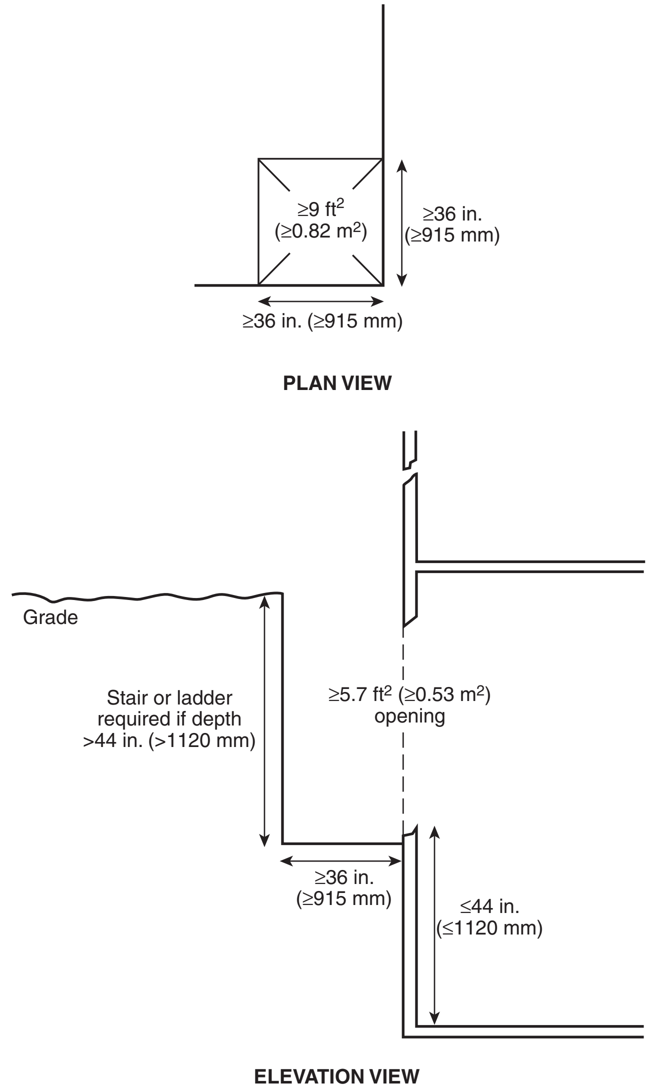

FIGURE A.24.2.2.3.3 Escape Window Utilizing a Window Well.

A.24.3.4.2.2 The placement requirements of NFPA 720, *Standard for the Installation of Carbon Monoxide (CO) Detection and Warning Equipment*, are modified specifically for one- and two-family dwellings as required by this *Code* and do not affect other regulations within a jurisdiction.

A.24.3.5 Automatic sprinklers are recognized as an excellent addition to homes to enhance life safety and property protection. Automatic sprinklers can be part of a comprehensive package of fire protection and can assist in the overall master planning of a community. Where all of the buildings within an area are sprinklered, including the single-family dwellings, the response times and personnel of local fire departments can be established at different levels than if the buildings were not sprinklered, saving considerable amounts of tax dollars. When whole developments are sprinklered, water mains, hydrant spacing, road widths, and building density can be altered to help alleviate the economic impact of the sprinklers.

A.26.1.1.1 Bed and breakfast occupancies with more than 3, but fewer than 17, occupants are considered lodging and rooming houses.

A.26.2.3.5.1 It is the intent of this requirement that security measures, where installed, do not prevent egress.

A.26.3.1.2 Such protection can be accomplished by separation by physical distance, arrangement of the stairs, protection of the openings exposing the stairs, or a combination thereof.

A.26.3.4.3.1 The proprietor is the owner or owner's agent with responsible charge.

A.26.3.4.6.2 The placement requirements of NFPA 720, *Standard for the Installation of Carbon Monoxide (CO) Detection and Warning Equipment*, are modified to accommodate lodging or rooming house occupancies that are part of multiple occupancy buildings (e.g., an on-call physicians' sleeping room in a hospital). The placement requirements of NFPA 720 are modified specifically for lodging or rooming houses as required by this *Code* and do not affect other regulations within a jurisdiction.

A.26.3.6.2.3 The decision to permit the use of the criteria from NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, in these occupancies is based on the following:

(1) The desire to obtain a level of fire suppression and control that is approximately equivalent to that delivered by residential facilities protected by such systems *(see A.1.1 in NFPA 13D)*
(2) The fact that potential fire exposure and challenge to the suppression system in a small lodging and rooming occupancy is of the same nature and no more severe than that found in residences

A.28.2.2.12.2 The provision of 28.2.2.12.2 permits the entire floor to serve as an area of refuge where it is protected in accordance with 28.3.5. The provision is acceptable because supervised automatic sprinkler systems have built-in signals for monitoring features of the system, such as the opening and closing of water control valves. Such systems also monitor pump power supplies, water tank levels, and conditions that will impair the satisfactory operation of the sprinkler system. Because of these monitoring features, supervised automatic sprinkler systems have a high level of satisfactory performance and response to fire conditions.

A.28.2.3.3 The exemption contained in 28.2.3.3 applies to corridors within an individual room or suite and does not apply where a suite can be subdivided and rented separately.

A.28.2.7.2 Where open stairways are permitted, they are considered as exit access to exits rather than as exits, and the requirements for travel distance to exits include the travel on such stairs. *(See 7.6.3.)*

A.28.3.4.3.1 Visible signaling appliances might be governed by provisions of federal regulations in 28 CFR 36, Appendix A, "Americans with Disabilities Act Accessibility Guidelines for Buildings and Facilities," Section 4.28, Alarms.

A.28.3.4.3.3 A quantity of such rooms and suites might be required to be equipped to accommodate hearing-impaired individuals based on the total number of rooms in a transient lodging facility. *(See 28 CFR 36, Appendix A, "Americans with Disabilities Act Accessibility Guidelines for Buildings and Facilities.")*

A.28.3.4.5 Caution needs to be exercised in locating smoke alarms with regard to their proximity to bathrooms, cooking facilities, and HVAC outlets in order to prevent nuisance alarms.

A.28.4.1.2 See 4.8.2.1(4).

A.28.5.3.2 "Protected power supply" means a source of electrical energy of sufficient capacity to allow proper operation of the elevator and its associated control and communications systems. The power supply's point of origin, system of distribution, type and size of overcurrent protection, degree of isolation from other portions of the building electrical system, and degree of mechanical protection should be such that it is unlikely that the supply would be disrupted at any but the advanced stages of building fire involvement or by structural collapse.

A protected power supply might consist of, and should provide, not less than the level of reliability associated with an electrical distribution system with service equipment located and installed in accordance with 230.72(B) and 230.82(5) of *NFPA 70, National Electrical Code*. The distribution system is not to have any other connection to the building electrical distribution system. A protected power supply is not required to incorporate two sources of energy or automatic transfer capability from a normal to an emergency source; for example, an alternate set of service conductors.

The number and type of elevators to be connected to a protected power supply should be limited, or the characteristics of the protected power supply should be selected to ensure conformance to 230.95 of *NFPA 70*, without the provision of ground fault protection for the supply.

An elevator installation supplied by a protected power supply should comply with Article 620 of *NFPA 70* and ASME A17.1/CSA B44, *Safety Code for Elevators and Escalators*. The energy absorption means should always be connected on the load side of the disconnecting means. The energy absorption means should not consist of loads likely to become inoperative or disconnected under the conditions assumed to exist when the elevator is under the control of fire department personnel. Examples of such loads include light and power loads external to the elevator equipment room.

A.28.7.1.1 Employers are obligated to determine the degree to which employees are to participate in emergency activities. Regulations of the U.S. Department of Labor (OSHA) govern these activities and provide options for employers, from total evacuation to aggressive structural fire fighting by employee brigades. *(For additional information, see 29 CFR 1910, Subparts E and L, "OSHA Regulations for Emergency Procedures and Fire Brigades.")*

A.28.7.1.2 Emergencies should be assumed to have arisen at various locations in the occupancy in order to train employees in logical procedures.

A.28.7.4.1 Floor diagrams should reflect the actual floor arrangement and should be oriented with the actual direction to the exits.

A.28.7.4.2 Factors for developing the fire safety information include such items as construction type, suppression systems, alarm and detection systems, building layout, and building HVAC systems.

A.29.2.2.8 Due to the nature of escalators, they are no longer acceptable as a component in a means of egress. However, because many escalators have been used for exit access and exit discharge in the past, they are permitted to continue to be considered in compliance. Very few escalators have ever been installed in a manner to qualify as an exit. For information on escalator protection and requirements, see previous editions of the *Code*.

A.29.2.2.12.2 The provision of 29.2.2.12.2 permits the entire floor to serve as an area of refuge where it is protected in accordance with 29.3.5. The provision is acceptable because supervised automatic sprinkler systems have built-in signals for monitoring features of the system, such as the opening and closing of water control valves. Such systems also monitor pump power supplies, water tank levels, and conditions that will impair the satisfactory operation of the sprinkler system. Because of these monitoring features, supervised automatic sprinkler systems have a high level of satisfactory performance and response to fire conditions.

A.29.2.7.2 Where open stairways or escalators are permitted, they are considered as exit access to exits rather than as exits, and the requirements for travel distance to exits include the travel on such stairs and escalators. *(See 7.6.3.)*

A.29.3.4.3.6 The provision for immediate notification of the public fire department is intended to include, but is not limited to, all of the arrangements in 9.6.4.2. Other arrangements that depend on a clerk or other member of the staff to notify the fire department might also be permitted. In such cases, however, it is essential that a trained staff member and an immediately available means of calling the fire department are continuously available. If a telephone is to be used, it should not be of any type or arrangement that requires a coin or the unlocking of a device to contact the fire department.

A.29.3.4.5 Caution needs to be exercised in locating smoke alarms with regard to their proximity to bathrooms, cooking facilities, and HVAC outlets in order to prevent nuisance alarms.

A.29.3.5.3 Although not required by the *Code*, the use of residential sprinklers or quick-response sprinklers is encouraged for new installations of sprinkler systems within dwelling units, apartments, and guest rooms. Caution should be exercised, as the system needs to be designed for the sprinkler being used.

A.29.4.1.2 See 4.8.2.1(4).

A.29.7.1.1 Employers are obligated to determine the degree to which employees are to participate in emergency activities. Regulations of the U.S. Department of Labor (OSHA) govern these activities and provide options for employers, from total evacuation to aggressive structural fire fighting by employee brigades. *(For additional information, see 29 CFR 1910, Subparts E and L, "OSHA Regulations for Emergency Procedures and Fire Brigades.")*

A.29.7.1.2 Emergencies should be assumed to have arisen at various locations in the occupancy in order to train employees in logical procedures.

A.29.7.4.1 Floor diagrams should reflect the actual floor arrangement and should be oriented with the actual direction to the exits.

A.29.7.4.2 Factors for developing the fire safety information include such items as construction type, suppression systems, alarm and detection systems, building layout, and building HVAC systems.

A.30.2.2.2.2.1 It is the intent of this requirement that security measures, where installed, should not prevent egress.

A.30.2.2.12.2 The provision of 30.2.2.12.2 permits the entire floor to serve as an area of refuge where it is protected in accordance with 31.3.5. The provision is acceptable because supervised automatic sprinkler systems have built-in signals for monitoring features of the system, such as the opening and closing of water control valves. Such systems also monitor pump power supplies, water tank levels, and conditions that will impair the satisfactory operation of the sprinkler system. Because of these monitoring features, supervised automatic sprinkler systems have a high level of satisfactory performance and response to fire conditions.

A.30.3.4.5 Previous editions of the *Code* permitted the single-station smoke alarm required by 30.3.4.5 to be omitted from each apartment where a complete automatic smoke detection system was installed throughout the building. With such a system, when one detector is activated, an alarm is sounded throughout the building. Experience with complete smoke detection systems in apartment buildings has shown that numerous nuisance alarms are likely to occur. Where there is a problem with frequent nuisance alarms, occupants ignore the alarm, or the system is either disconnected or otherwise rendered inoperative.

A.30.3.5.3 The 12 ft^2 (1.1 m^2) closet sprinkler exemption differs from requirements in NFPA 13, *Standard for the Installation of Sprinkler Systems*, because fire loss data supports the long-standing position of the *Code*, since the 1976 edition, to omit sprinklers from such closets. The provision is further supported by the lack of losses in buildings protected in accordance with NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, and NFPA 13R, *Standard for the Installation of Sprinkler Systems in Low-Rise Residential Occupancies*, which permit the omission of sprinklers from closets not exceeding 24 ft^2 (2.2 m^2).

A.30.3.5.4 The provision of 30.3.5.4 differs from NFPA 13, *Standard for the Installation of Sprinkler Systems*, because fire data shows that in apartment fires where sprinklers were present, bathrooms were the area of origin in 1 percent of the total fires, and resulted in no civilian deaths, civilian injuries, or property loss.

A.30.4.1.2 See 4.8.2.1(4).

A.31.1 See Table A.31.1.

A.31.2.2.8 Due to the nature of escalators, they are no longer acceptable as a component in a means of egress. However, because many escalators have been used for exit access and exit discharge in the past, they are permitted to continue to be considered in compliance. Very few escalators have ever been installed in a manner to qualify as an exit. For information on escalator protection and requirements, see previous editions of the *Code*.

A.31.2.2.12.2 The provision of 31.2.2.12.2 permits the entire floor to serve as an area of refuge where it is protected in accordance with 31.3.5. The provision is acceptable because supervised automatic sprinkler systems have built-in signals for monitoring features of the system, such as the opening and closing of water control valves. Such systems also monitor pump power supplies, water tank levels, and conditions that will impair the satisfactory operation of the sprinkler system. Because of these monitoring features, supervised automatic sprinkler systems have a high level of satisfactory performance and response to fire conditions.

A.31.2.4.6 This single-exit exemption could be applied to an apartment building three stories in height with a basement.

Table A.31.1 Alternate Requirements for Existing Apartment Buildings According to Protection Provided

Feature	No Suppression or Detection System Option 1	Complete Automatic Fire Detection Option 2	Automatic Sprinkler Protection in Selected Areas Option 3	Automatic Sprinkler Protection Throughout per NFPA 13 (with exceptions) Option 4
Exit Access				
Travel distance from apartment door to exit	100 ft (30 m)	150 ft (46 m)	150 ft (46 m)	200 ft (61 m)
Travel distance within apartment	75 ft (23 m)	125 ft (38 m)	75 ft (23 m)	125 ft (38 m)
Smoke barrier required *(See 31.3.7.)*	R	R	R	NR
Maximum single path corridor distance	35 ft (10.7 m)	35 ft (10.7 m)	35 ft (10.7 m)	35 ft (10.7 m)
Maximum dead end	50 ft (15 m)	50 ft (15 m)	50 ft (15 m)	50 ft (15 m)
Corridor fire resistance				
Walls	½ hr	½ hr	½ hr	½ hr
Doors (fire protection rating)	20 min. or 1¾ in. (44 mm) thick	20 min. or 1¾ in. (44 mm) thick	Smoke resisting	Smoke resisting
Interior Finish				
Lobbies and corridors	A or B	A or B	A or B	A, B, or C
Other spaces	A, B, or C	A, B, or C	A, B, or C	A, B, or C
Floors in corridors	I or II	I or II	NR	NR
Exits				
Wall fire resistance				
1–3 stories†	1 hr	1 hr	1 hr	1 hr
>3 stories†	2 hr	2 hr	2 hr	1 hr
Smokeproof enclosures				
Not high-rise	NR	NR	NR	NR
High-rise	R	R	R	NR
Door fire resistance				
1–3 stories†	1 hr	1 hr	1 hr	1 hr
>3 stories†	1½ hr	1½ hr	1½ hr	1 hr
Interior finish				
Walls and ceilings	A or B	A or B	A or B	A, B, or C
Floors	I or II	I or II	I or II	NR
Within Living Unit (Apartment)				
Escape windows, per Section 24.2 *(See 31.2.1.)*	R	R	R	NR
Alarm System				
>3 stories or >11 units†	Manual initiation	Manual and auto initiation	Manual and auto initiation	Manual and auto initiation
>2 stories or >50 units†	Annunciator panel	Annunciator panel	Annunciator panel	Annunciator panel

R: Required *(see Code for details and exemptions)*. NR: No requirements.
† Number of stories in height.

A.31.2.11.1 The provision of 31.2.11 recognizes the need to provide smoke control in existing buildings. Smokeproof enclosures can be accomplished without the use of a vestibule in accordance with 7.2.3.

A.31.3.4.4.1 It is intended that a building compliant with Option 2 function as described in the paragraph that follows.

Occupants within a living unit become aware of a fire emergency, either through personal awareness or through being alerted by the smoke alarm(s) installed within the living unit. Other building occupants are alerted to the fire emergency by the building fire alarm system that is initiated by manual fire alarm boxes adjacent to the exits, heat detection within the living unit where the fire emergency exists, smoke detection in the common areas outside the living unit, or a combination thereof. The installation of system heat detectors versus smoke detectors within the living unit is intended to eliminate nuisance-type alarms and reduce occupant complacency from frequent false alarms. The installation of smoke detection within the living unit should only be contemplated after a careful analysis of the goals and with the approval of the authority having jurisdiction.

A.31.3.4.5.1 NFPA *101* provides adequate, balanced fire protection and takes into consideration the passive and active systems required in a given occupancy. The level of protection prescribed by *NFPA 72, National Fire Alarm and Signaling Code*, which includes smoke alarms in all sleeping rooms, without exception, does not necessarily take into consideration the complete protection package mandated by NFPA *101.*

A.31.3.5.2 Although not required by the *Code*, the use of residential sprinklers or quick-response sprinklers is encouraged for new installations of sprinkler systems within dwelling units, apartments, and guest rooms. Caution should be exercised, because the system needs to be designed for the sprinkler being used.

A.31.3.5.4 The provision of 31.3.5.4 differs from NFPA 13, *Standard for the Installation of Sprinkler Systems*, because fire data shows that in apartment fires where sprinklers were present, bathrooms were the area of origin in 1 percent of the total fires, and resulted in no civilian deaths, civilian injuries, or property loss.

A.31.3.5.11 For example, if an Option 3 sprinkler system were being used to justify use of Class C wall finish in an exit enclosure, the sprinkler system would need to be extended into the exit enclosure, even if the rest of the requirements for Option 3 did not require the sprinklers in the exit enclosure.

A.31.3.5.12.3 This system might consist of a combination of any or all of the following systems:

(1) Partial automatic sprinkler protection
(2) Smoke detection alarms
(3) Smoke control
(4) Compartmentation or other approved systems, or both

A.31.3.6.1 The intent is to recognize that existing partitions of sound wood lath and plaster, wire lath and plaster, or gypsum lath and plaster construction have demonstrated the ability to contain most room fires. Recent data on archaic construction methods have established the fire resistance rating of such construction at about 20 minutes. Such construction meets the intent of 31.3.6.1.

A.31.4.1.2 See 4.8.2.1(4).

A.32.1.6 The provisions of 8.3.1(4) address a ½-hour fire resistance rating. The information in A.8.3.1.1(4) addresses common materials used in barriers having a minimum ½-hour fire resistance rating.

A.32.2.2.3.1(3) A window with dimensions of 20 in. × 24 in. (510 mm × 610 mm) has an opening of 3.3 ft^2 (0.31 m^2), which is less than the required 5.7 ft^2 (0.53 m^2). Therefore, either the height or width needs to exceed the minimum requirement to provide the required clear area.

A.32.2.2.6.3 Exterior stair protection can be accomplished through separation by physical distance, arrangement of the stairs, protection of the openings exposing the stairs, or other means acceptable to the authority having jurisdiction.

A.32.2.3.2.1 Spaces containing approved, properly installed and maintained furnaces and heating equipment, furnace rooms, and cooking and laundry facilities should not be classified as hazardous areas solely on the basis of such equipment.

A.32.2.3.5 All sprinkler systems installed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*, and NFPA 13R, *Standard for the Installation of Sprinkler Systems in Low-Rise Residential Occupancies*, are required to be inspected, tested, and maintained in accordance with NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*. However, systems installed in accordance with NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, are historically exempt from applying NFPA 25. While there is a great deal of information in NFPA 25 that is not appropriate for NFPA 13D sprinkler systems, there are some basic concepts of inspection, testing, and maintenance that are critical to system performance and must be performed when an NFPA 13D sprinkler system is installed in a board and care occupancy. The frequencies mandated by this *Code* are slightly different from those required by NFPA 25. It is the intent of this *Code* to utilize the frequencies stated in Chapter 32, but to reference the purpose and the procedures for the inspections, tests, and maintenance from NFPA 25.

A.32.2.3.5.1 Where any provision requires the use of an automatic sprinkler system in accordance with 32.2.3.5, the provision of 32.2.3.5.2 is not permitted to be used.

A.32.2.3.5.2 Where a facility utilizing the provision of 32.2.3.5.2 is occupied by residents who can no longer comply with the 3-minute evacuation response, 33.1.8 requires the facility to comply with the requirements for new construction, including automatic sprinkler protection. *(See also A.33.1.8.)*

A.32.2.3.5.3.2 The decision to permit the use of the criteria from NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, in these occupancies is based on the following:

(1) The desire to obtain a level of fire suppression and control approximately equivalent to that delivered by residential facilities protected by such systems *(see A.1.1 in NFPA 13D)*
(2) The fact that potential fire exposure and challenge to the suppression system in a small board and care facility are of the same nature and are no more severe than those found in residences

Chapter 32 permits the use of NFPA 13D, and NFPA 13R, *Standard for the Installation of Sprinkler Systems in Low-Rise Residential Occupancies*, outside of their scopes. This permission is based on a review of the occupancy and a recognition that the fires in board and care facilities are similar to those of other residential occupancies and that the level of protection is appropriate. The requirements of NFPA 13D and NFPA 13R have been supplemented with requirements for additional water supplies to compensate for the special needs of the board and care occupancy.

NFPA 13D contains additional requirements for a piping system serving both sprinkler and domestic needs.

A.32.3.3.3 The provisions in 10.2.8 to permit modifications to interior finish requirements where automatic sprinklers are provided are permitted.

A.32.3.3.4.6 Positive alarm sequence applies only to emergency forces notification. Occupant notification is required to occur immediately upon activation of the detection device or system.

A.32.3.3.6 It is not the intent to prohibit furniture in corridors and spaces open to corridors, provided that the minimum required width is maintained. Storage is not permitted in corridors or spaces open to corridors. It is also not the intent to require corridors to be defined by a change in flooring texture, material, or color to separate them from areas allowed to be open to corridors.

Cooking facilities complying with 32.3.3.8 are permitted to be open to corridors. Sleeping rooms are required to be separated from means of egress in accordance with 32.3.3.6.

A.32.3.3.7.10 Where the smoke control system design requires dampers in order that the system functions effectively, it is not the intent of 32.3.3.7.10 to permit the damper to be omitted.

The term *fully ducted* means the supply and return-air systems are provided with continuous ducts from all air registers to the air-handling unit.

A.32.3.3.7.13 Smoke barrier doors are intended to provide access to adjacent zones. The pair of cross-corridor doors are required to be opposite swinging. Access to both zones is required.

A.32.3.3.7.17 Smoke barriers might include walls having door openings other than cross-corridor doors. There is no restriction in the *Code* regarding which doors or how many doors form part of a smoke barrier. For example, doors from the corridor to individual rooms are permitted to form part of a smoke barrier.

A.32.3.3.7.18 It is not the intent to require the frame to be a listed assembly.

A.32.3.3.8.2 This provision is intended to permit small appliances used for reheating, such as microwave ovens, hot plates, toasters, and nourishment centers to be exempt from the requirements for commercial cooking equipment and hazardous area protection.

A.32.3.3.8.3 The intent of 32.3.3.8.3 is to limit the number of persons for whom meals are routinely prepared to not more than 30. Staff and feeding assistants are not included in this number.

A.32.3.3.8.3(4) The minimum airflow of 500 cfm (14,000 L/m) is intended to require the use of residential hood equipment at the higher end of equipment capacities. It is also intended to draw a sufficient amount of the cooking vapors into the grease baffle and filter system to reduce migration beyond the hood.

A.32.3.3.8.3(7) The intent of this provision is to limit cooking fuel to gas or electricity. The prohibition of solid fuels for cooking is not intended to prohibit charcoal grilling on grills located outside the facility.

A.32.3.3.8.3(8) Deep-fat frying is defined as a cooking method that involves fully immersing food in hot oil.

A.32.3.3.8.3(10) The intent of this requirement is that the fuel source for the cooktop or range is to be turned on only when staff is present or aware that the kitchen is being used. The timer function is meant to provide an additional safeguard if the staff forgets to deactivate the cooktop or range. If a cooking activity lasts longer than 120 minutes, the timer would be required to be manually reset.

A.32.3.3.8.3(12) The intent of requiring smoke alarms instead of smoke detectors is to prevent false alarms from initiating the building fire alarm system and notifying the fire department. Smoke alarms should be maintained a minimum of 20 ft (6.1 m) away from the cooktop or range as studies have shown this distance to be the threshold for significantly reducing false alarms caused by cooking. The intent of the interconnected smoke alarms, with silence feature, is that while the devices would alert staff members to a potential problem, if it is a false alarm, the staff members can use the silence feature instead of disabling the alarm. The referenced study indicates that nuisance alarms are reduced with photoelectric smoke alarms. Providing two interconnected alarms provides a safety factor since they are not electrically supervised by the the fire alarm system. *(Smoke Alarms – Pilot Study of Nuisance Alarms Associated with Cooking)*

A.32.3.3.8.4 The provisions of 32.3.3.8.4 differ from those of 32.3.3.8.3, as they apply to cooking equipment that is separated from the corridor.

A.32.3.3.8.5 The provision of 32.3.3.8.5 clarifies that protected commercial cooking equipment does not require an enclosure (separation) as a hazardous area in accordance with Section 8.7, as is required by 32.3.3.2.

A.32.3.6.3.2 "Protected power supply" means a source of electrical energy of sufficient capacity to allow proper operation of the elevator and its associated control and communications systems. The power supply's point of origin, system of distribution, type and size of overcurrent protection, degree of isolation from other portions of the building electrical system, and degree of mechanical protection should be such that it is unlikely that the supply would be disrupted at any but the advanced stages of building fire involvement or by structural collapse.

A protected power supply might consist of, and should provide, not less than the level of reliability associated with an electrical distribution system with service equipment located and installed in accordance with 230.72(B) and 230.82(5) of *NFPA 70, National Electrical Code*. The distribution system is not to have any other connection to the building electrical distribution system. A protected power supply is not required to incorporate two sources of energy or automatic transfer capability from a normal to an emergency source; for example, an alternate set of service conductors.

The number and type of elevators to be connected to a protected power supply should be limited, or the characteristics of the protected power supply should be selected to ensure conformance with 230.95 of *NFPA 70*, without the provision of ground fault protection for the supply.

An elevator installation supplied by a protected power supply should comply with Article 620 of *NFPA 70*, except that the energy absorption means required by 620.91 of *NFPA 70* should always be connected on the load side of the disconnecting means. The energy absorption means should not consist of loads likely to become inoperative or disconnected under the conditions assumed to exist when the elevator is under the control of fire department personnel. Examples of such loads include light and power loads external to the elevator equipment room.

A.32.4 Board and care occupancies in apartment buildings will usually be small facilities housing 16 or fewer residents. It is intended that the board and care occupancy conform to the requirements of Section 32.2 for small board and care facilities. In the unusual case where an apartment houses a large board and care facility, it would be reasonable for the authority having jurisdiction, using the requirement of 4.6.1, to apply the provisions of Section 32.3 to the apartment. In addition, the apartment building in which the facility is housed needs to comply with the requirements for apartment buildings in Chapters 30 and 31 and the additional criteria presented in Section 32.4.

A.32.4.1.3 In determining equivalency for conversions, modernizations, renovations, or unusual design concepts, the authority having jurisdiction might permit evaluations based on the residential board and care occupancies fire safety evaluation system (FSES) of NFPA 101A, *Guide on Alternative Approaches to Life Safety.*

A.32.7.3.3 An assembly point can be located outside the building, in a separate building, or in an adjacent smoke compartment in the same building.

A.32.7.4.1 Smoking regulations should include the following:

(1) Smoking should be prohibited in any room, compartment, or area where flammable or combustible liquids, combustible gases, or oxygen is used or stored and in any other hazardous location, and the following also should apply:
   (a) Such areas should be posted with signs that read NO SMOKING or the international symbol for no smoking.
   (b) In residential board and care facilities where smoking is totally prohibited and signs so indicating are placed at all major entrances, secondary signs with language that prohibits smoking are not required.
(2) Smoking by residents classified as not responsible with regard to their ability to safely use and dispose of smoking materials should be prohibited.
(3) Where a resident, as specified in A.32.7.4.1(2), is under direct supervision by staff or by a person approved by the administration, smoking might be permitted.
(4) Smoking materials should not be provided to residents or maintained by residents without the approval of the administration.
(5) Areas where smoking is permitted should be clearly identified.
(6) Ashtrays of noncombustible material and safe design should be provided and required to be used in all areas where smoking is permitted.
(7) Self-closing cover devices into which ashtrays can be emptied should be made available to all areas where smoking is permitted and should be required to be used.

A.32.7.5 The requirements applicable to draperies/curtains, upholstered furniture, and mattresses apply only to new draperies/curtains, new upholstered furniture, and new mattresses. The term *new* means unused, normally via procurement from the marketplace, either by purchase or donation, of items not previously used. Many board and care facilities allow residents to bring into the board and care home upholstered furniture items from the resident's previous residence. Such items are not new and, thus, are not regulated. On the other hand, some of the larger board and care homes purchase contract furniture, as is done in hotels. Such new, unused furniture, whether purchased or received as a donation, is regulated by the requirements of 32.7.5.2. By federal law, mattresses manufactured and sold within the United States must pass testing per 16 CFR 1632, "Standard for the Flammability of Mattresses and Mattress Pads" (FF4-72).

A.32.7.5.2 New upholstered furniture within board and care homes should be tested for rates of heat release in accordance with 10.3.3.

A.32.7.5.3 New mattresses within board and care homes should be tested for rates of heat release in accordance with 10.3.4.

A.33.1.1 The requirements of Chapter 33 are designed to accommodate typical changes in the capabilities of the resident, such as those due to accidents, temporary illness, cyclical variations in capabilities, and gradual aging. This approach is based on the assumption that the capabilities of the resident will be evaluated not less than annually, and for residents with geriatric problems or degenerative diseases, not less than every 6 months. Also, residents should be re-evaluated after each accident or illness that requires hospitalization.

The requirements of Chapter 33 were developed on the assumption that the occupants will normally evacuate the building in fire emergencies. During fire exit drills, all occupants should evacuate the building with staff assistance, as needed. Exceptions can be made in facilities with an evacuation capability rating of impractical. Managers of board and care homes with nursing home backgrounds sometimes are not aware of the differences between the requirements of 19.7.1 and 33.7.3.

A.33.1.1.4 The provision of 33.1.1.4 was added after Chapter 32 was revised in its entirety to avoid potential conflicts between the two chapters. Occupancies meeting Chapter 32 requirements are deemed to comply with Chapter 33.

A.33.1.6 The provisions of 8.3.1(4) address a ½-hour fire resistance rating. The information in A.8.3.1.1(4)(4) addresses common materials used in barriers having a minimum ½-hour fire resistance rating.

A.33.1.8 When the group evacuation capability changes to a level of greater risk, the owner/operator of the facility needs to take such action as is necessary, within a reasonable time frame, to restore the evacuation capability of the facility to that for which it was approved. If subsequent evaluations indicate that the original evacuation capability of the facility cannot or is not being maintained at the original level of risk, the facility would be considered as having changed the occupancy subclassification to one of greater risk, and the safeguards required for the level of greater risk would apply. If a facility improves its original evacuation capability to one of less risk, a re-evaluation and upgrading to the requirements for new construction are not needed.

A.33.2.1.2.1.1 In determining equivalency for existing buildings, conversions, modernizations, renovations, or unusual design concepts, the authority having jurisdiction might permit evaluations based on the residential board and care occupancies fire safety evaluation system (FSES) of NFPA 101A, *Guide on Alternative Approaches to Life Safety.*

A.33.2.2.3.1(3) A window with dimensions of 20 in. × 24 in. (510 mm × 610 mm) has an opening of 3.3 ft^2 (0.31 m^2), which is less than the required 5.7 ft^2 (0.53 m^2). Therefore, either the height or width needs to exceed the minimum requirement to provide the required clear area.

A.33.2.2.6.3 Exterior stair protection can be accomplished through separation by physical distance, arrangement of the stairs, protection of the openings exposing the stairs, or other means acceptable to the authority having jurisdiction.

A.33.2.3.4.3 Most often, smoke alarms sounding an alarm at 85 dBA or greater, installed outside the bedroom area, will meet the intent of this requirement. Smoke alarms remotely located from the bedroom might not be loud enough to awaken the average person. In such cases, it is recommended that smoke alarms be interconnected so that the activation of any smoke alarm will cause all smoke alarms to activate.

NFPA *101* provides adequate, balanced fire protection and takes into consideration the passive and active systems required in a given occupancy. The level of protection prescribed by *NFPA 72, National Fire Alarm and Signaling Code*, which includes smoke alarms in all sleeping rooms, without exception, does not necessarily take into consideration the complete protection package prescribed by NFPA *101*.

A.33.2.3.5 All sprinkler systems installed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*, and NFPA 13R, *Standard for the Installation of Sprinkler Systems in Low-Rise Residential Occupancies*, are required to be inspected, tested, and maintained in accordance with NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*. However, systems installed in accordance with NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, are historically exempt from applying NFPA 25. While there is a great deal of information in NFPA 25 that is not appropriate for NFPA 13D sprinkler systems, there are some basic concepts of inspection, testing, and maintenance that are critical to system performance and must be performed when an NFPA 13D sprinkler system is installed in a board and care occupancy. The frequencies mandated by this *Code* are slightly different from those required by NFPA 25. It is the intent of this *Code* to utilize the frequencies stated in Chapter 32, but to reference the purpose and the procedures for the inspections, tests, and maintenance from NFPA 25.

A.33.2.3.5.3.1 The decision to permit the use of the criteria from NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, in these occupancies is based on the following:

(1) The desire to obtain a level of fire suppression and control approximately equivalent to that delivered by residential facilities protected by such systems *(see A.1.1 in NFPA 13D)*
(2) The fact that potential fire exposure and challenge to the suppression system in a small board and care facility are of the same nature and are no more severe than those found in residences

Chapter 33 permits the use of NFPA 13D and NFPA 13R, *Standard for the Installation of Sprinkler Systems in Low-Rise Residential Occupancies*, outside of their scopes. This permission is based on a review of the occupancy and a recognition that the fires in board and care facilities are similar to those of other residential occupancies and that the level of protection is appropriate. In some circumstances, such as those for impractical evacuation capabilities, the requirements of NFPA 13D and NFPA 13R have been supplemented with requirements for additional water supplies to compensate for the special needs of the board and care occupancy.

A.33.3.1.2.1.1 In determining equivalency for existing buildings, conversions, modernizations, renovations, or unusual design concepts, the authority having jurisdiction might permit evaluations based on the residential board and care occupancies fire safety evaluation system (FSES) of NFPA 101A, *Guide on Alternative Approaches to Life Safety*.

A.33.3.3.4.6.1 See A.29.3.4.3.6.

A.33.3.3.5.1 It is intended that this requirement apply to existing small facilities that are converted to large facilities.

Chapter 33 permits the use of NFPA 13D, *Standard for the Installation of Sprinkler Systems in One- and Two-Family Dwellings and Manufactured Homes*, and NFPA 13R, *Standard for the Installation of Sprinkler Systems in Low-Rise Residential Occupancies*, outside of their scopes. This permission is based on a review of the occupancy and a recognition that the fires in board and care facilities are similar to those of other residential occupancies and that the level of protection is appropriate. In some circumstances, such as those for impractical evacuation capabilities, the requirements of NFPA 13D and NFPA 13R have been supplemented with requirements for additional water supplies to compensate for the special needs of the board and care occupancy.

A.33.3.3.8.2 This provision is intended to permit small appliances used for reheating, such as microwave ovens, hot plates, toasters, and nourishment centers to be exempt from the requirements for commercial cooking equipment and hazardous area protection.

A.33.3.3.8.3 The intent of 33.3.3.8.3 is to limit the number of persons for whom meals are routinely prepared to not more than 30. Staff and feeding assistants are not included in this number.

A.33.3.3.8.3(4) The minimum airflow of 500 cfm (14,000 L/m) is intended to require the use of residential hood equipment at the higher end of equipment capacities. It is also intended to draw a sufficient amount of the cooking vapors into the grease baffle and filter system to reduce migration beyond the hood.

A.33.3.3.8.3(7) The intent of this provision is to limit cooking fuel to gas or electricity. The prohibition of solid fuels for cooking is not intended to prohibit charcoal grilling on grills located outside the facility.

A.33.3.3.8.3(8) Deep-fat frying is defined as a cooking method that involves fully immersing food in hot oil.

A.33.3.3.8.3(10) The intent of this requirement is that the fuel source for the cooktop or range is to be turned on only when staff is present or aware that the kitchen is being used. The timer function is meant to provide an additional safeguard if the staff forgets to deactivate the cooktop or range. If a cooking activity lasts longer than 120 minutes, the timer would be required to be manually reset.

A.33.3.3.8.3(12) The intent of requiring smoke alarms instead of smoke detectors is to prevent false alarms from initiating the building fire alarm system and notifying the fire department. Smoke alarms should be maintained a minimum of 20 ft (6.1 m) away from the cooktop or range as studies have shown this distance to be the threshold for significantly reducing false alarms caused by cooking. The intent of the interconnected smoke alarms, with silence feature, is that while the devices would alert staff members to a potential problem, if it is a false alarm, the staff members can use the silence feature instead of disabling the alarm. The referenced study indicates that nuisance alarms are reduced with photoelectric smoke alarms. Providing two interconnected alarms provides a safety factor since they are not electrically supervised by the fire alarm system *(Smoke Alarms — Pilot Study of Nuisance Alarms Associated with Cooking)*.

A.33.3.3.8.4 The provisions of 33.3.3.8.4 differ from those of 33.3.3.8.3, as they apply to cooking equipment that is separated from the corridor.

A.33.3.3.8.5 The provision of 33.3.3.8.5 clarifies that protected commercial cooking equipment does not require an enclosure (separation) as a hazardous area in accordance with Section 8.7, as is required by 33.3.3.2.

A.33.4 Board and care occupancies in apartment buildings will usually be small facilities housing 16 or fewer residents. It is intended that the board and care occupancy conform to the requirements of Section 33.2 for small board and care facilities. In the unusual case where an apartment houses a large board and care facility, it would be reasonable for the authority having jurisdiction, using the requirement of 4.6.1, to apply the provisions of Section 33.3 to the apartment. In addition, the apartment building in which the facility is housed needs to comply with the requirements for apartment buildings in Chapters 30 and 31 and the additional criteria presented in Section 33.4.

A.33.4.1.3.1 In determining equivalency for existing buildings, conversions, modernizations, renovations, or unusual design concepts, the authority having jurisdiction might permit evaluations based on the residential board and care occupancies fire safety evaluation system (FSES) of NFPA 101A, *Guide on Alternative Approaches to Life Safety*.

A.33.7.3.3 An assembly point can be located outside the building, in a separate building, or in an adjacent smoke compartment in the same building.

A.33.7.4.1 Smoking regulations should include the following:

(1) Smoking should be prohibited in any room, compartment, or area where flammable or combustible liquids, combustible gases, or oxygen is used or stored and in any other hazardous location, and the following also should apply:
   (a) Such areas should be posted with signs that read NO SMOKING or the international symbol for no smoking.
   (b) In residential board and care facilities where smoking is totally prohibited and signs so indicating are placed at all major entrances, secondary signs with language that prohibits smoking are not required.
(2) Smoking by residents classified as not responsible with regard to their ability to safely use and dispose of smoking materials should be prohibited.
(3) Where a resident, as specified in A.33.7.4.1(2), is under direct supervision by staff or by a person approved by the administration, smoking might be permitted.
(4) Smoking materials should not be provided to residents or maintained by residents without the approval of the administration.
(5) Areas where smoking is permitted should be clearly identified.
(6) Ashtrays of noncombustible material and safe design should be provided and required to be used in all areas where smoking is permitted.
(7) Self-closing cover devices into which ashtrays can be emptied should be made available to all areas where smoking is permitted and should be required to be used.

A.33.7.5 The requirements applicable to draperies/curtains, upholstered furniture, and mattresses apply only to new draperies/curtains, new upholstered furniture, and new mattresses. The term *new* means unused, normally via procurement from the marketplace, either by purchase or donation, of items not previously used. Many board and care facilities allow residents to bring into the board and care home upholstered furniture items from the resident's previous residence. Such items are not new and, thus, are not regulated. On the other hand, some of the larger board and care homes purchase contract furniture, as is done in hotels. Such new, unused furniture, whether purchased or received as a donation, is regulated by the requirements of 33.7.5.2. By federal law, mattresses manufactured and sold within the United States must pass testing per 16 CFR 1632, "Standard for the Flammability of Mattresses and Mattress Pads" (FF 4-72).

A.33.7.5.2 New upholstered furniture within board and care homes should be tested for rates of heat release in accordance with 10.3.3.

A.33.7.5.3 New mattresses within board and care homes should be tested for rates of heat release in accordance with 10.3.4.

A.36.1.3.2.2(4) Means to prevent spilled fuel from accumulating and entering the mercantile occupancy building can be by curbs, scuppers, special drainage systems, sloping the floor away from the door openings, or floor elevation differences of not less than 4 in. (100 mm).

A.36.2.2.2.2 The words "principal entrance/exit doors" describe doors that the authority having jurisdiction can reasonably expect to be unlocked in order for the facility to do business.

A.36.2.2.7.2 Egress from a mall building should be designed as follows:

(1) The mall/pedestrian way has been assigned no occupant load, but it is required to be provided with means of egress sized to accommodate the total occupant load of the mall building based on the gross leasable area.
(2) The exits for the mall/pedestrian way are permitted to be provided by a combination of exterior exit doors and exit passageways.
(3) After completion of A.36.2.2.7.2(1), each tenant space is to be judged individually for occupant load and egress capacity, and the following also apply:
   (a) The step specified in A.36.2.2.7.2(3) normally sends a portion or all (per 36.4.4.4.2) of the tenant space's occupant load into the mall.
   (b) Any remaining occupants are sent through the back of the tenant space into an exit passageway that might serve multiple tenant spaces and the mall.
(4) The width of the exit passageway is required to be sized for the most restrictive of the following:
   (a) Width of not less than 66 in. (1675 mm) per 36.4.4.4.2(3)
   (b) Portion of the egress capacity from the largest single tenant space being served by the exit passageway
   (c) Portion of the egress capacity from the mall being provided by the exit passageway

The concepts used in A.36.2.2.7.2(4)(a) through (c) include the following:

(1) After proper egress capacity is provided for the mall/pedestrian way, each tenant space is then required to independently provide egress capacity for its occupants.
(2) The mall required exit passageway width and the tenant space required exit passageway width are not required to be added together.
(3) The required exit passageway width for a tenant space is not required to be added to that of other tenant spaces using the same exit passageway.

A.36.2.5.10 To eliminate the obstruction to the means of egress of the interior exit access and the exterior exit discharge, it is the intent to provide adequate area for transit and parking of wheeled carts or buggies used by customers. This area includes corral areas adjacent to exits that are constructed to restrict the movement of wheeled carts or buggies therefrom.

A.36.2.7.2 The basis for the exemption to the general rule on complete enclosure of exits up to their point of discharge to the outside of the building is that, with the specified safeguards, reasonable safety is maintained.

A stairway is not considered to discharge through the street floor area if it leads to the street through a fire resistance–rated enclosure (exit passageway) separating it from the main area, even though there are doors between the first-floor stairway landing and the main area.

The provisions of 36.2.7.2 should not be confused with those for open stairways, as permitted by 36.3.1(1).

A.36.3.2.1 It is the intent to permit a suspended natural gas–fired unit heater that complies with the requirements of 9.2.2 to be installed and used in a mercantile occupancy without classifying the area in which it is located as hazardous.

A.36.3.2.1.1 These areas can include, but are not limited to, areas used for general storage, boiler or furnace rooms, and maintenance shops that include woodworking and painting areas.

A.36.3.2.2 The requirement for separating high hazard contents areas from other parts of the building is intended to isolate the hazard, and 8.2.3.3 is applicable.

A.36.3.2.3 It is not the intent to prohibit the use of equipment that is used less frequently and does not produce significant grease-laden vapors such as that equipment used for cooking demonstrations.

A.36.3.6.1 The intent of 36.3.6.1(2) and (3) is to permit spaces within single tenant spaces, or within buildings protected throughout by an approved, supervised automatic sprinkler system, to be open to the exit access corridor without separation.

A.36.4.4.2(5) A mall building might enclose one or more uses, such as retail and wholesale stores, drinking and dining establishments, entertainment and amusement facilities, transportation facilities, offices, and other similar uses.

A.36.4.4.4.2(3) The minimum requirement for terminating mall exit access in not less than 66 in. (1675 mm) of egress width relates to the minimum requirement for not less than one aisle in Class A mercantile occupancies with 30,000 ft^2 (2800 m^2) or greater sales area to be 60 in. (1525 mm) in width.

A.36.4.4.4.2(5) Walls providing tenant separations are only required to extend to the underside of the ceiling assembly, regardless of the ceiling's fire-resistive rating. If a ceiling is not provided in either of the tenant spaces, then the wall should extend to the underside of the roof or floor above.

A.36.4.4.4.2(6) Fire experience in mall shopping centers indicates that the most likely place of fire origin is in the tenant space, where the combustible fire load is far greater than in the mall. Furthermore, any fires resulting from the comparatively low fire load in the mall are more likely to be detected and extinguished in their incipient stages. Early detection is likely due to the nature of the mall as a high-traffic pedestrian way. Such fires produce less smoke development in a greater volume of space than fires in the more confined adjacent tenant space. Smoke control systems that address fire experience in malls are necessary to ensure the integrity of the mall as a pedestrian way by maintaining it reasonably free of the products of combustion for a duration not less than that required to evacuate the area of the building that is affected by the fire. Secondary considerations should include the following:

(1) Confinement of the products of combustion to the area of origin
(2) Removal of the products of combustion, with a minimum of migration of such products of combustion from one tenant space to another
(3) Achievement of evacuation without the need for smoke control in one- and two-level mall buildings protected by automatic sprinklers

Systems, or combinations of systems, that can be engineered to address fires in malls of three or more levels include the following:

(1) Separate mechanical exhaust or control systems
(2) Mechanical exhaust or control systems in conjunction with heating, ventilating, and air-conditioning systems
(3) Automatically or manually released gravity roof vent devices, such as skylights, relief dampers, or smoke vents
(4) Combinations of items (1), (2), and (3) in this list, or any other engineered system designed to accomplish the purpose of this section

A.36.4.4.6.5 It is not the intent of 36.4.4.6.5 to require that large tenant spaces be considered anchor stores. A tenant space not considered in determining the occupant load of the mall is required to be arranged so that all of its means of egress will be independent of the mall.

A.36.4.4.7.3.2 It is the intent to permit the omission of visible alarm notification appliances from the mall or pedestrian way in mall buildings. It is anticipated that occupants with hearing impairments will receive cues from other building occupants and respond accordingly. Visible signals should be provided in public restrooms and other adjunct spaces in the mall subject to occupancy solely by persons with hearing impairments.

A.36.4.4.9.2 Rooms opening onto the exit passageway are intended to include building service elevators, elevator machine rooms, electrical rooms, telephone rooms, janitor closets, restrooms, and similar normally unoccupied spaces not requiring hazardous area protection in accordance with Section 8.7.

A.36.4.4.12 Fire experience in mall shopping centers indicates that the most likely place of fire origin is in the tenant space where the combustible fire load is far greater than in the mall.

Furthermore, any fires resulting from the comparatively low fire load in the mall are more likely to be detected and extinguished in their incipient stages. Early detection is likely due to the nature of the mall as a high-traffic pedestrian way. Such fires produce less smoke development in a greater volume of space than fires in the more confined adjacent tenant space.

Smoke control systems that address fire experience in malls are necessary in order to achieve the following:

(1) Ensure the integrity of the mall as a pedestrian way by maintaining it reasonably free of the products of combustion for a duration not less than that required to evacuate the building
(2) Confine the products of combustion to the area of origin
(3) Remove the products of combustion with a minimum of migration of such products of combustion from one tenant to another

Systems, or combinations of systems, that can be engineered to address fires in malls include the following:

(1) Separate mechanical exhaust or control systems
(2) Mechanical exhaust or control systems in conjunction with heating, ventilating, and air-conditioning systems
(3) Automatically or manually released gravity roof vent devices, such as skylights, relief dampers, or smoke vents
(4) Combinations of items (1), (2), and (3) in this list, or any other engineered system designed to accomplish the purpose of this section

A.37.1.3.2.2(4) Means to prevent spilled fuel from accumulating and entering the mercantile occupancy building can be by curbs, scuppers, special drainage systems, sloping the floor away from the door openings, or elevation differences of not less than 4 in. (100 mm).

A.37.2.2.2.2 The words "principal entrance/exit doors" describe doors that the authority having jurisdiction can reasonably expect to be unlocked in order for the facility to do business.

A.37.2.2.7.2 Egress from a mall building should be designed as follows:

(1) The mall/pedestrian way has been assigned no occupant load, but it is required to be provided with means of egress sized to accommodate the total occupant load of the mall building based on the gross leasable area.
(2) The exits for the mall/pedestrian way are permitted to be provided by a combination of exterior exit doors and exit passageways.
(3) After completion of A.37.2.2.7.2(1), each tenant space is to be judged individually for occupant load and egress capacity, and the following also apply:
    (a) The step specified in A.37.2.2.7.2(3) normally sends a portion or all (per 37.4.4.4.2) of the tenant space's occupant load into the mall.
    (b) Any remaining occupants are sent through the back of the tenant space into an exit passageway that might serve multiple tenant spaces and the mall.
(4) The width of the exit passageway is required to be sized for the most restrictive of the following:
    (a) Width of not less than 66 in. (1675 mm) per 37.4.4.4.2(3)
    (b) Portion of the egress capacity from the largest single tenant space being served by the exit passageway
    (c) Portion of the egress capacity from the mall being provided by the exit passageway

The concepts used in A.37.2.2.7.2(4)(a) through (c) include the following:

(1) After proper egress capacity is provided for the mall/pedestrian way, each tenant space is then required to independently provide egress capacity for its occupants.
(2) The mall required exit passageway width and the tenant space required exit passageway width are not required to be added together.
(3) The required exit passageway width for a tenant space is not required to be added to that of other tenant spaces using the same exit passageway.

A.37.2.5.2 The purpose of 37.2.5.2 is to avoid pockets or dead ends of such size that they pose an undue danger of persons becoming trapped in case of fire.

It is recognized that dead ends exceeding the permitted limits exist and, in some cases, are impractical to eliminate. The authority having jurisdiction might permit such dead ends to continue to exist, taking into consideration any or all of the following:

(1) Tenant arrangement
(2) Automatic sprinkler protection
(3) Smoke detection
(4) Exit remoteness

A.37.2.5.3 It is recognized that common paths of travel exceeding the permitted limits exist and, in some cases, are impractical to eliminate. The authority having jurisdiction might permit such paths of travel to continue to exist, taking into consideration any or all of the following:

(1) Tenant arrangement
(2) Automatic sprinkler protection
(3) Smoke detection
(4) Exit remoteness

A.37.2.5.10 To eliminate the obstruction to the means of egress of the interior exit access and the exterior exit discharge, it is the intent to provide adequate area for transit and parking of wheeled carts or buggies used by customers. This area includes corral areas adjacent to exits that are constructed to restrict the movement of wheeled carts or buggies therefrom.

A.37.2.7.2 The basis for the exemption to the general rule on complete enclosure of exits up to their point of discharge to the outside of the building is that, with the specified safeguards, reasonable safety is maintained.

A stairway is not considered to discharge through the street floor area if it leads to the street through a fire resistance–rated enclosure (exit passageway) separating it from the main area, even though there are doors between the first floor stairway landing and the main area.

The provisions of 37.2.7.2 should not be confused with those for open stairways, as permitted by 37.3.1(1) and (2).

A.37.3.2.1 It is the intent to permit a suspended natural gas–fired unit heater that complies with the requirements of 9.2.2 to be installed and used in a mercantile occupancy without classifying the area in which it is located as hazardous.

A.37.3.2.1.1 These areas can include, but are not limited to, areas used for general storage, boiler or furnace rooms, and maintenance shops that include woodworking and painting areas.

A.37.3.2.2 The requirement for separating high hazard contents areas from other parts of the building is intended to isolate the hazard, and 8.2.3.3 is applicable.

A.37.3.2.3 It is not the intent to prohibit the use of equipment that is used less frequently and does not produce significant grease-laden vapors such as that equipment used for cooking demonstrations.

A.37.4.4.2(5) A mall building might enclose one or more uses, such as retail and wholesale stores, drinking and dining establishments, entertainment and amusement facilities, transportation facilities, offices, and other similar uses.

A.37.4.4.4.2(3) The minimum requirement for terminating mall exit access in not less than 66 in. (1675 mm) of egress width relates to the minimum requirement for not less than one aisle in Class A mercantile occupancies with 30,000 ft^2 (2800 m^2) or greater sales area to be 60 in. (1525 mm) in width.

A.37.4.4.4.2(6) Fire experience in mall shopping centers indicates that the most likely place of fire origin is in the tenant space, where the combustible fire load is far greater than in the mall. Furthermore, any fires resulting from the comparatively low fire load in the mall are more likely to be detected and extinguished in their incipient stages. Early detection is likely due to the nature of the mall as a high-traffic pedestrian way. Such fires produce less smoke development in a greater volume of space than fires in the more confined adjacent tenant space. Smoke control systems that address fire experience in malls are necessary to ensure the integrity of the mall as a pedestrian way by maintaining it reasonably free of the products of combustion for a duration not less than that required to evacuate the area of the building that is affected by the fire. Secondary considerations should include the following:

(1) Confinement of the products of combustion to the area of origin
(2) Removal of the products of combustion, with a minimum of migration of such products of combustion from one tenant space to another
(3) Achievement of evacuation without the need for smoke control in one- and two-level mall buildings protected by automatic sprinklers

Systems, or combinations of systems, that can be engineered to address fires in malls of three or more levels include the following:

(1) Separate mechanical exhaust or control systems
(2) Mechanical exhaust or control systems in conjunction with heating, ventilating, and air-conditioning systems
(3) Automatically or manually released gravity roof vent devices, such as skylights, relief dampers, or smoke vents
(4) Combinations of items (1), (2), and (3) in this list, or any other engineered system designed to accomplish the purpose of this section

A.37.4.4.6.5 It is not the intent of 37.4.4.6.5 to require that large tenant spaces be considered anchor stores. A tenant space not considered in determining the occupant load of the mall is required to be arranged so that all of its means of egress will be independent of the mall.

A.37.4.4.9.2 Rooms opening onto the exit passageway are intended to include building service elevators, elevator machine rooms, electrical rooms, telephone rooms, janitor closets, restrooms, and similar normally unoccupied spaces not requiring hazardous area protection in accordance with Section 8.7.

A.38.1.3.2.2(4) Means to prevent spilled fuel from accumulating and entering the business occupancy building can be by curbs, scuppers, special drainage systems, sloping the floor away from the door openings, or elevation differences not less than 4 in. (100 mm).

A.38.2.2.2.2 The words "principal entrance/exit doors" describe doors that the authority having jurisdiction can reasonably expect to be unlocked in order for the facility to do business.

A.38.2.3.2 It is not the intent that this provision apply to noncorridor or nonpassageway areas of exit access, such as the spaces between rows of desks created by office layout or low-height partitions.

A.38.3.2.1 It is not the intent of this provision that rooms inside individual tenant spaces that are used to store routine office supplies for that tenant be required to be either separated or sprinklered.

A.38.3.2.2 The requirement for separating high hazard contents areas from other parts of the building is intended to isolate the hazard, and 8.2.3.3 is applicable.

A.38.3.2.3 It is not the intent to prohibit the use of equipment that is used less frequently and does not produce significant grease-laden vapors such as that equipment used for cooking demonstrations.

A.38.3.6.1 The intent of 38.3.6(1) through (3) is to permit spaces to be open to the exit access corridor without separation.

A.38.3.6.1(1) Where exits are available from an open floor area, such as open plan buildings, corridors are not required to be separated. An example of an open plan building is a building in which the work spaces and accesses to exits are delineated by the use of tables, desks, bookcases, or counters, or by partitions that are less than floor-to-ceiling height.

A.38.3.6.1(2) It is the intent of this provision that a single tenant be limited to an area occupied under a single management and work the same hours. The concept is that people under the same employ working the same hours would likely be familiar with their entire tenant space. It is not the intent to apply this provision simply because tenants are owned by the same organization. For example, in a government-owned office building, the offices of different federal agencies would be considered multiple tenants, because an employee normally works for one agency. The agencies might work various hours. Another example of multiple tenancy would be a classroom building of a university, because some classrooms might be in use at times when other classrooms are not being used.

A.39.1.3.2.2(4) Means to prevent spilled fuel from accumulating and entering the business occupancy building can be by curbs, scuppers, special drainage systems, sloping the floor away from the door openings, or elevation differences not less than 4 in. (100 mm).

A.39.2.2.2.2 The words "principal entrance/exit doors" describe doors that the authority having jurisdiction can reasonably expect to be unlocked in order for the facility to do business.

A.39.2.5.2 It is recognized that dead ends exceeding the permitted limits exist and, in some cases, are impractical to eliminate. The authority having jurisdiction might permit such dead ends to continue to exist, taking into consideration any or all of the following:

(1) Tenant arrangement
(2) Automatic sprinkler protection
(3) Smoke detection
(4) Exit remoteness

A.39.2.5.3 It is recognized that common paths of travel exceeding the permitted limits exist and, in some cases, are impractical to eliminate. The authority having jurisdiction might permit such common paths of travel to continue to exist, taking into consideration any or all of the following:

(1) Tenant arrangement
(2) Automatic sprinkler protection
(3) Smoke detection
(4) Exit remoteness

A.39.3.2.1 It is not the intent of this provision that rooms inside individual tenant spaces that are used to store routine office supplies for that tenant be required to be separated or sprinklered.

A.39.3.2.2 The requirement for separating high hazard contents areas from other parts of the building is intended to isolate the hazard, and 8.2.3.3 is applicable.

A.39.3.2.3 It is not the intent to prohibit the use of equipment that is used less frequently and does not produce significant grease-laden vapors such as that equipment used for cooking demonstrations.

A.39.4.2.2 In some cases, appreciable cost might be involved in bringing an existing occupancy into compliance. Where this is true, it would be appropriate for the authority having jurisdiction to prescribe a schedule determined jointly with the facility, allowing suitable periods of time for the correction of the various deficiencies and giving due weight to the ability of the owner to secure the necessary funds.

A.40.1.2.1.3 Additional information on the definition of high hazard industrial occupancy can be found in A.3.3.190.8.2.

A.40.1.7 In most cases, the requirements for maximum travel distance to exits will be the determining factor, rather than number of occupants, because exits provided to satisfy travel distance requirements will be sufficient to provide egress capacity for all occupants, except in cases of an unusual arrangement of buildings or the high occupant load of a general manufacturing occupancy.

A.40.2.1.2 Horizontal and vertical utility chases in large industrial buildings used for routing of piping, ducts, and wiring must provide a reasonable level of access for occasional maintenance workers but do not warrant compliance with the comprehensive egress requirements of Chapter 7. Minimum access in these cases is governed by electrical and mechanical codes; 40.2.5.2, Industrial Equipment Access; and the Occupational Safety and Health Administration (OSHA) for facilities in the United States. Utility chases governed by 40.2.1.2 might involve tunnels or large open spaces located above or below occupied floors; however, such spaces differ from mechanical equipment rooms, boiler rooms, and furnace rooms, based on the anticipated frequency of use by maintenance workers. Portions of utility chases where the anticipated presence of maintenance workers is routine are not intended to be included by this paragraph.

A.40.2.2.5.2 The customary building code requirement for fire doors on both sides of an opening in a fire wall is permitted to be met by having an automatic-sliding fire door on one side and a self-closing fire door swinging out from the other side of the wall. This arrangement qualifies only as a horizontal exit from the sliding door side. For further information, see A.7.2.4.3.10.

A.40.2.5.2.1 Ancillary facilities located within industrial occupancies might include administrative office, laboratory, control, and employee service facilities that are incidental to the predominant industrial function and are of such size that separate occupancy classification is not warranted.

A.40.2.5.2.2 Occupants of ancillary facilities located within special-purpose industrial occupancies might be required by administrative controls to remain in the facility when a fire occurs in the predominant industrial area, so that they can perform an orderly shutdown of process equipment to control the spread of the fire and minimize damage to important equipment or perform other safety or security functions.

A.40.2.6.2 See NFPA 850, *Recommended Practice for Fire Protection for Electric Generating Plants and High Voltage Direct Current Converter Stations*, for protection recommendations.

A.40.2.9 The authority having jurisdiction should review the facility and designate the stairs, aisles, corridors, ramps, and passageways that should be required to be provided with emergency lighting. In large locker rooms or laboratories using hazardous chemicals, for example, the authority having jurisdiction should determine that emergency lighting is needed in the major aisles leading through those spaces.

A.40.3.2 Emergency lighting should be considered where operations require lighting to perform orderly manual emergency operation or shutdown, maintain critical services, or provide safe start-up after a power failure.

A.40.6 For further information on aircraft hangars, see NFPA 409, *Standard on Aircraft Hangars*.

A.42.1.7 There is no occupant load factor specified for storage occupancies. Rather, the probable maximum number of persons present needs to be considered in determining the occupant load.

A.42.2.1.2 Horizontal and vertical utility chases in large industrial buildings used for routing of piping, ducts, and wiring must provide a reasonable level of access for occasional maintenance workers but do not warrant compliance with the comprehensive egress requirements of Chapter 7. Minimum access in these cases is governed by the electrical and mechanical code; 40.2.5.2, Industrial Equipment Access; and the Occupational Safety and Health Administration (OSHA) for facilities in the United States. Utility chases governed by 42.2.1.2 might involve tunnels or large open spaces located above or below occupied floors; however, such spaces differ from mechanical equipment rooms, boiler rooms, and furnace rooms, based on the anticipated frequency of use by maintenance workers. Portions of utility chases where the anticipated presence of maintenance workers is routine are not intended to be included by this paragraph.

A.42.2.2.5.2 The customary building code requirement for fire doors on both sides of an opening in a fire wall is permitted to be met by having an automatic-sliding fire door on one side and a self-closing fire door swinging out from the other side of the wall. This arrangement qualifies only as a horizontal exit from the sliding door side. For further information, see A.7.2.4.3.10.

A.42.2.6 The travel distance to exits specified recognizes a low population density. Consideration should be given to locating areas that have a relatively high population, such as lunchrooms, meeting rooms, packaging areas, and offices, near the outside wall of the building to keep the travel distance to a minimum.

A.42.6 For further information on aircraft hangars, see NFPA 409, *Standard on Aircraft Hangars*.

A.42.7 For further information, see NFPA 61, *Standard for the Prevention of Fires and Dust Explosions in Agricultural and Food Processing Facilities*. The egress requirements for storage elevators are based on the possibility of fire and are not based on the possibility of grain dust explosions.

A.42.8.1.1 For further information on garages, including a definition of the term *open garage*, see NFPA 88A, *Standard for Parking Structures*.

A.43.2.2.1.4 It is not the intent that a corridor, aisle, or circulation space within a suite be considered as a corridor that is shared by more than one occupant space. The suite should be considered as only one occupant space. The following situations should be considered to involve more than one occupant space:

(1) Work affecting a corridor that is common to multiple guest rooms on a floor of a hotel occupancy
(2) Work affecting a corridor that is common to multiple living units on a floor of an apartment building occupancy
(3) Work affecting a corridor that is common to multiple tenants on a floor of a business occupancy

A.43.2.2.2 Equipment or fixtures do not include manufacturing, production, or process equipment, but do include connections from building service to process equipment.

A.43.4.2(2) Some building codes have permitted an increase in egress capacity in buildings protected throughout by an approved automatic sprinkler system. The intent of 43.4.2(2) is that, during a renovation project, egress capacity is permitted to continue to be evaluated using the previously approved method.

A.43.6.2.2 The provisions for marking of means of egress are those addressed in Section 7.10.

A.43.7.2.1(2) It is not the intent of 43.7.2.1(2) to supersede the provision of 32.2.3.5.2 that exempts automatic sprinklers from small board and care facility conversions serving eight or fewer residents when all occupants have the ability as a group to move reliably to a point of safety within 3 minutes.

A.43.7.3 Table 43.7.3 groups all the residential occupancy classifications into the general category of residential. The category of residential includes one- and two-family dwellings, lodging or rooming houses, hotels and dormitories, and apartment buildings. A change from one residential occupancy, as defined in 6.1.8.1 through 6.1.8.1.5, to another residential occupancy is classified as the rehabilitation work category of *change of occupancy* and subject to the requirements of 43.7.2.

Annex B Supplemental Evacuation Equipment

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only. Information in this annex is intended to be adopted by the jurisdiction at the discretion of the adopting jurisdiction. Additionally, information in this annex is intended to be incorporated on a voluntary basis by building owners and developers who might have a desire to include supplemental evacuation equipment in their projects.

Although this annex is written in mandatory language, it is not intended to be enforced or applied unless specifically adopted by the jurisdiction or, if it is being applied on a voluntary basis, by the building owner or developer.

Note: Traditionally, supplemental evacuation equipment has not been regulated or recognized by the *Code*. Until recently, such equipment was considered to include only items such as chain ladders and rope fire escape ladders for use in single-family homes. The criteria specified in Annex B also provides no regulation or recognition for the private installation and use of such equipment by an owner and family, while providing a framework of regulations for the use of controlled descent devices and platform rescue systems in commercial and residential multistory buildings. The broader term *supplemental evacuation equipment* provides for subsets of equipment to be added as further technologies develop.

B.1 General.

B.1.1 Definitions.

B.1.1.1 Controlled Descent Device. A system operating on the exterior of a building or structure that lowers one or two people per descent, each wearing a rescue harness, at a controlled rate from an upper level to the ground or other safe location.

B.1.1.2 Platform Rescue System. An enclosed platform, or set of enclosed platforms, moving vertically along guides or other means on the exterior of a building or structure, intended for the evacuation of multiple occupants from an upper level or levels to the ground or other safe location, that has the capability of transporting emergency responders to upper levels of a building.

B.1.1.3 Supplemental Escape Device or System. Dedicated equipment that supplements the means of egress or means of escape for exiting a building or structure.

Note: Supplemental escape devices and systems are not a substitute for the required means of egress or means of escape. If properly installed, maintained, and used, controlled descent devices and platform rescue systems might provide an added means of escape for the occupants where the required means of egress or means of escape is not usable or accessible, and where the event that has caused failure of the required system has not also impaired the functionality of the device or system itself.

B.1.1.4 Supplemental Evacuation Equipment. Devices or systems that are not a part of the required means of egress or escape, but that might enhance use of the means of egress or escape, or provide an alternate to the means of egress or escape.

B.1.2 Reserved.

B.2 Supplemental Escape Devices or Systems. A supplemental escape device or system, other than that provided or installed for use by the owner and owner's family, and the installation of such device or system, shall comply with Section B.3 or Section B.4, as appropriate, and the following criteria:

Note: The provisions of Section B.2 are not intended to preclude the installation of supplemental escape devices or systems that do not meet these requirements where intended for personal use, such as by an owner and family.

It should be recognized that supplemental escape devices or systems addressed by these requirements are intended to be used only when all other means of egress are unusable and when remaining in place to await the restoration of the means of egress is considered untenable.

Generally, fire departments have the capability of providing external rescue of building occupants within reach of their portable ladders, aerial ladders, and aerial platform devices. Where a fire department responds to a building emergency and has the capability to provide timely assistance with external rescue, that assistance should be used instead of the supplemental escape devices or systems.

(1) Each supplemental escape device or system shall be of an approved type and shall comply with an approved product safety standard.
(2) The installation of escape devices or systems shall be approved. Note: Use of a supplemental escape device or system typically requires that a window or exterior door be opened. The window or door should be closed, except when it is in use for escape. Where the design of the building does not provide exterior doors or operable windows and a window must be broken to use the device or system, consideration should be given to the probable effect of that action, such as showering the emergency

response personnel and equipment below with sharp pieces of glass. In such a situation, to obtain approval, it might be appropriate to require tempered safety glass on windows that must be broken to deploy the supplemental escape device and access the system.

(3) The supplemental escape device or system shall be installed, inspected, tested, maintained, and used in accordance with the manufacturer's instructions.

(4) The location of each supplemental escape system access point shall be identified with a readily visible sign complying with the following:
   (a) The sign shall be in plainly legible letters that read SUPPLEMENTAL ESCAPE DEVICE.
   (b) The minimum height of the lettering shall be ¾ in. (19 mm), with a stroke width of ⅛ in. (3 mm).

(5) Each sign required by B.2(4) shall comply with the following:
   (a) The sign shall include the following in plainly legible letters: "Use only when exits are not accessible and building evacuation is imperative, as directed by authorized building personnel or emergency responders."
   (b) The minimum height of the lettering shall be ½ in. (13 mm).

(6) A sign with instructions for use of the escape device or system shall be provided and shall comply with the following:
   (a) The sign shall be posted at the equipment and the equipment's access location.
   (b) The minimum height of lettering on the instructions shall be ½ in. (13 mm).
   (c) Pictographs demonstrating use of the escape device or system shall be provided. Note: Given the nature of the probable circumstances surrounding its deployment, the proper use of the supplemental escape device or system should be readily apparent to the user or trained operator.

(7) The signs and instructions specified in B.2(4), (5), and (6) shall be illuminated as follows:
   (a) The signs shall be continuously illuminated while the building is occupied.
   (b) The level of illumination provided shall be in accordance with 7.10.6.3, 7.10.7.2, or an approved equivalent.

(8) Where emergency lighting is required by Chapters 11 through 43, it shall be provided as follows:
   (a) The illumination shall be in accordance with 7.9.1.
   (b) The level of illumination required by 7.9.2.1 shall be provided to illuminate the supplemental escape device or system at its access location and the required signage.

(9) The supplemental escape device or system and its installation shall accommodate persons with various disabilities and of all ages. Note: It is not the intent of B.2(9) that access ramps, doorways, controls, signage, and other features of the supplemental escape device or system meet all requirements for accessibility for persons with disabilities. The equipment is supplemental in nature and is not recognized as part of the required means of egress. A number of other occupants should be trained to assist persons with disabilities to access the equipment. In selecting the equipment and approving the installation, consideration should be given to how persons with mobility impairments will access the equipment. Even when exit stairs are usable, elevators might not be able to be used. Use of a supplemental escape device or system to evacuate persons with mobility impairments might be desirable. Such circumstances should be considered and incorporated into the facility's evacuation plan, which should also identify the trained operators authorized to deploy the equipment for such use.

(10) The installation shall be approved such that use of the supplemental escape device or system shall not cause any harm or injury to the user, operator, or others who might be in the vicinity of the equipment when in use.

(11) Where an evacuation plan is required by Chapters 11 through 43, or by other regulation, an approved, written evacuation plan shall be provided as follows:
   (a) The plan shall be in accordance with 4.8.2.
   (b) The plan shall not rely on the use of supplemental escape devices and systems but shall accommodate the use of such a system by specifying the following:
      i. Role of the supplemental escape device or system in the overall plan
      ii. Role and authority of emergency response personnel with respect to the supplemental escape device or system
      iii. Person or persons authorized to direct the deployment of, and to operate, the escape device or system
      iv. Special considerations, if any, that affect the usability of the supplemental escape device or system
      v. Training required for operators and users
   (c) Note: An evacuation plan can be a highly effective tool in determining who should be evacuated under various scenarios and how that evacuation will be accomplished. Even where none is required, an evacuation plan is recommended to identify, among other things, those persons who are authorized to deploy supplemental escape devices and systems. The more sophisticated the equipment and the greater the number of potential evacuees, the greater is the need to have a trained and authorized person decide which equipment to deploy and when it should be deployed, based on the circumstances at the time. Such a person would be the incident commander, typically the emergency response officer in charge, whether from a private brigade or public service. Even where a building or facility is not required to have an approved evacuation plan by the *Code*, the supplemental escape device or system operating procedures should be integrated into the building evacuation and emergency procedures to the extent provided.

(12) User and operator training shall be provided in conjunction with the installation of the supplemental escape device or system, and periodically thereafter.

(13) Where an approved evacuation plan is required, training shall be provided in accordance with the approved plan.

(14) The supplemental escape device or system shall be inspected and tested in accordance with the manufacturer's instructions but not less frequently than annually, and the following also shall apply:

(a) Notification of testing shall be provided to building occupants or the authority having jurisdiction, as appropriate.
(b) Written records of the inspection and testing shall be maintained by the owner for a minimum of 1 year after the next scheduled inspection and testing. Note: It is important that the supplemental escape device or system does not remain idle for many years in order to help ensure that it will be functional if it does need to be used. The manufacturer's instructions for the particular model of equipment involved should be followed.

(15) Supplemental escape devices and systems shall be listed, certified, or approved to operate as intended over the prevalent climatic conditions for the location in which they are installed.

B.3 Platform Rescue Systems. Where platform rescue systems are installed or provided, they shall comply with the following:

(1) The platform rescue system shall comply with ASTM E 2513, *Standard Specification for Multi-Story Building External Evacuation Platform Rescue Systems*, or an approved, equivalent product safety standard.
(2) The platform rescue system shall be deployed with trained operators to assist with evacuation of occupants.
(3) Where a fixed installation of electrical or other type power is required to operate the platform rescue system, a redundant source of power shall be provided.
(4) The installation shall be designed such that the vertical distance to be traversed by the platform rescue system shall not exceed the limit specified in the product's listing, certification, or approved installation.
(5) The platform access from within buildings shall be by ramps or stairs, and the following also shall apply:
   (a) Portable ramps and stairs shall be permitted.
   (b) The maximum slope of a ramp shall be as low as practical, but shall not be required to be less than 1 in 8.
   (c) The maximum riser height of stairs shall be 9 in. (230 mm).
   (d) The minimum tread depth of stairs shall be 9 in. (230 mm).
(6) The platform access opening shall be sized in accordance with the following:
   (a) For installations in new construction, the platform access opening shall be a minimum 32 in. (810 mm) in width and a minimum 48 in. (1220 mm) in height.
   (b) For installations in existing construction, the platform access opening shall be as large as practical but shall not be required to exceed 32 in. (810 mm) in width and 48 in. (1220 mm) in height.
(7) The platform access and egress shall not be by ladders.
(8) Rooftop operating equipment and systems shall be protected from accumulations of climatic ice or snow and fire suppression ice.

B.4 Controlled Descent Devices. Where controlled descent devices are installed or provided, they shall comply with the following:

(1) The controlled descent device shall comply with ASTM E 2484, *Standard Specification for Multi-Story Building External Evacuation Controlled Descent Devices*, or an approved, equivalent product safety standard.
(2) The installation shall be designed such that the vertical distance to be traversed by the controlled descent device shall not exceed the limit specified in the product's listing, certification, or approved installation.
(3) Where a fixed installation of electrical or other type power is required to operate the controlled descent device, a redundant source of power shall be provided.
(4) Rooftop operating equipment and systems shall be protected from accumulations of climatic ice or snow and fire suppression ice.
(5) Controlled descent device building access openings in new building installations shall be a minimum of 32 in. (810 mm) wide and 42 in. (1065 mm) high.
(6) Controlled descent device building access openings in existing buildings shall be a minimum of 20 in. (510 mm) wide and 24 in. (610 mm) high and shall provide a clear opening of not less than 5.7 ft^2 (0.53 m^2).
(7) The approved occupant load and weight limits shall be posted adjacent to the controlled descent device installation or building access opening in minimum ½ in. (13 mm) letters, with a minimum 1⁄16 in. (1.6 mm) stroke.
(8) The occupant load and weight limits shall not be exceeded in use.

Guide on

Alternative Approaches to Life Safety

2016 Edition

This edition of NFPA 101A, *Guide on Alternative Approaches to Life Safety*, was prepared by the Technical Committee on Alternative Approaches to Life Safety and released by the Correlating Committee on Safety to Life. It was issued by the Standards Council on May 26, 2015, with an effective date of June 15, 2015, and supersedes all previous editions.

A Tentative Interim Amendment (TIA) to Worksheet 7.5.4(A) was issued on May 26, 2015. For further information on tentative interim amendments, see Section 5 of the Regulations Governing the Development of NFPA Standards, available at: http://www.nfpa.org/regs.

This edition of NFPA 101A was approved as an American National Standard on June 15, 2015.

Origin and Development of NFPA 101A

Prior to the development of the 1988 edition of this document, it was published as several appendixes to NFPA *101*®, *Life Safety Code*®. NFPA 101A is revised every three years on a schedule that lags that of NFPA *101* by one year so as to accurately reflect the requirements of NFPA *101*, against which the NFPA 101A Fire Safety Evaluation Systems (FSESs) measure equivalency.

Chapter 4 first appeared as Appendix C in the 1981 edition of the *Life Safety Code* and Chapters 5, 6, and 7 first appeared in the 1985 edition of the *Life Safety Code* as Appendixes E, F, and G. Chapter 8 was proposed as Appendix H for the 1988 edition of the *Life Safety Code* but instead was published as a chapter of the 1998 edition of NFPA 101A. These chapters were originally prepared by the Center for Fire Research of the National Institute of Standards and Technology (then the National Bureau of Standards). The Committees on Safety to Life have reviewed and modified the systems as appropriate for inclusion. Chapter 9 appeared first in the 2004 edition and provides an FSES for educational occupancies.

This document provides alternative approaches to life safety based on the 2012 *Life Safety Code*. It is intended to be used *with* the *Life Safety Code*, not as a substitute. Section 1.4 of the *Life Safety Code* permits alternative compliance with the *Code* under equivalency concepts where such equivalency is approved by the authority having jurisdiction. The methods contained in this guide can be used to help determine equivalency where used as part of the technical documentation submitted to the authority having jurisdiction.

The figures contained in this guide are copyrighted by NFPA, but users are hereby given permission to copy the worksheets for private use only.

The 2016 edition includes changes to the mandatory safety values in the various fire safety evaluation systems so that equivalency is measured accurately against the requirements of the 2015 edition of NFPA *101, Life Safety Code.*

NFPA 101A

Guide on

Alternative Approaches to Life Safety

2016 Edition

IMPORTANT NOTE: This NFPA document is made available for use subject to important notices and legal disclaimers. These notices and disclaimers appear in all publications containing this document and may be found under the heading "Important Notices and Disclaimers Concerning NFPA Documents." They can also be obtained on request from NFPA or viewed at www.nfpa.org/disclaimers.

UPDATES, ALERTS, AND FUTURE EDITIONS: New editions of NFPA codes, standards, recommended practices, and guides (i.e., NFPA Standards) are released on scheduled revision cycles. This edition may be superseded by a later one, or it may be amended outside of its scheduled revision cycle through the issuance of Tentative Interim Amendments (TIAs). An official NFPA Standard at any point in time consists of the current edition of the document, together with any TIAs and Errata in effect. To verify that this document is the current edition or to determine if it has been amended by any TIAs or Errata, please consult the National Fire Codes® Subscription Service or visit the Document Information (DocInfo) pages on the NFPA website at www.nfpa.org/docinfo. In addition to TIAs and Errata, the DocInfo pages also include the option to sign up for Alerts for each document and to be involved in the development of the next edition.

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates that explanatory material on the paragraph can be found in Annex A.

A reference in brackets [ ] following a section or paragraph indicates material that has been extracted from another NFPA document. As an aid to the user, the complete title and edition of the source documents for extracts in advisory sections of this document are given in Chapter 2 and those for extracts in the informational sections are given in Annex B. Extracted text may be edited for consistency and style and may include the revision of internal paragraph references and other references as appropriate. Requests for interpretations or revisions of extracted text should be sent to the technical committee responsible for the source document.

Information on referenced publications can be found in Chapter 2 and Annex B.

Chapter 1 Administration

1.1 Scope. (Reserved)

1.2 Purpose. (Reserved)

1.3 Application.

1.3.1* This guide consists of a number of alternative approaches to life safety. Each chapter is a different system independent of the others and is to be used in conjunction with the 2015 edition of NFPA *101.*

1.3.2 This edition of NFPA 101A contains alternative approaches that are tied to NFPA *101.* Each of these systems is recognized by the *Life Safety Code,* in its Annex A, as a method that can be used to assist the authority having jurisdiction in determining equivalent compliance with various chapters of the *Code.*

1.3.3 The method described in this guide is an index method. Index methods are a type of qualitative risk assessment. Quantitative risk assessments can also be used to evaluate designs that are proposed as alternative approaches to life safety. For information on developing fire risk assessments, see the *SFPE Engineering Guide to Fire Risk Assessment.* Guidance on reviewing fire risk assessments can be found in NFPA 551.

1.3.4 For further information on alternative approaches to fire safety, see "Systems Approach to Fire-Safe Building Design," Section 1, Chapter 9, of the 20th edition of the NFPA *Fire Protection Handbook* and the *SFPE Handbook of Fire Protection Engineering,* 4th edition, Section 3, "Hazard Calculations," and Section 5, Chapter 10, "Fire Risk Indexing."

Chapter 2 Referenced Publications

2.1 General. The documents or portions thereof listed in this chapter are referenced within this guide and should be considered part of the recommendations of this document.

2.2 NFPA Publications. National Fire Protection Association, 1 Batterymarch Park, Quincy, MA 02169-7471.

NFPA 13, *Standard for the Installation of Sprinkler Systems,* 2013 edition.

Chapter 3 Definitions

3.1 General. The definitions contained in this chapter apply to the terms used in this guide. Where terms are not defined in this chapter or within another chapter, they should be defined using their ordinarily accepted meanings within the context in which they are used. *Merriam-Webster's Collegiate Dictionary*, 11th edition, is the source for the ordinarily accepted meaning.

3.2 NFPA Official Definitions.

3.2.1* Approved. Acceptable to the authority having jurisdiction.

3.2.2* Authority Having Jurisdiction (AHJ). An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

3.2.3 Guide. A document that is advisory or informative in nature and that contains only nonmandatory provisions. A guide may contain mandatory statements such as when a guide can be used, but the document as a whole is not suitable for adoption into law.

3.2.4 Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

3.2.5* Listed. Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

3.2.6 Shall. Indicates a mandatory requirement.

3.2.7 Should. Indicates a recommendation or that which is advised but not required.

3.3 General Definitions. See Section 3.3 of NFPA *101.*

Chapter 4 Fire Safety Evaluation System for Health Care Occupancies

4.1 General.

4.1.1 This chapter is part of an NFPA guide and, therefore, is not mandatory. The term *shall* in this chapter is used to indicate that if the provisions of the chapter are applied, the procedures mandated are to be followed to ensure the effectiveness of the evaluation system.

4.1.2 The Fire Safety Evaluation System (FSES) is a measuring system. It compares the level of safety provided by an arrangement of safeguards that differ from those specified in NFPA *101* to the level of safety provided in a building that conforms exactly with the details of the *Code.*

4.1.3 This chapter is provided to assist in completion of Figure 4.7, Worksheets for Evaluating Fire/Smoke Zones. The step-by-step instructions for completion appear on the worksheets. They are not repeated within the chapter. This chapter provides expanded discussion and definition of the various items in the worksheet to assist the user when questions of definition or interpretation arise. The chapter is organized to follow the format of the worksheet progressively.

4.2 Procedure for Determining Equivalency.

4.2.1 Evaluate fire/smoke zones using Figure 4.7 (Worksheets 4.7.1 through 4.7.11). Use the text portion (Section 4.3 through 4.6.13.4.3) of this chapter as a guide.

4.2.2 The Facility Fire Safety Requirements Worksheet (Worksheet 4.7.10) is used to determine any nonconformance with the requirements on the worksheet.

4.2.3 Equivalency is achieved if the fire/smoke zone evaluations show equivalency or better in each and every fire/smoke zone and the requirements of the Facility Fire Safety Requirements Worksheet (Worksheet 4.7.10) are met.

4.3 Fire/Smoke Zone.

4.3.1 A fire/smoke zone is a space that is separated from all other spaces by floor assemblies, horizontal exits, or smoke barriers. Every zone on a story that is subdivided into two or more zones shall have exit routes in accordance with 18.2.4 or 19.2.4 of NFPA *101.* Compartments not meeting these requirements shall be evaluated as part of an adjacent zone. Where a story is not subdivided by horizontal exits or smoke barriers, the entire story is considered to be the zone.

4.3.2 Selection of Zones to Be Evaluated.

4.3.2.1 A story that is not subdivided by horizontal exits or smoke barriers is considered a single zone.

4.3.2.2 The entire facility shall be divided into zones. There shall be no areas that are not in a zone.

4.3.2.3 For a complete evaluation, evaluate every zone in the health care facility individually.

4.3.2.4 Where the system is used to evaluate conditions unique to a selected number of zones, the entire building should be evaluated for compliance with the *Life Safety Code* and the FSES evaluation shall be completed on the specific zones where the condition occurs.

4.3.2.5 Most health care facilities have repetitive arrangements so that a complete picture can be developed by evaluating typical zones until all combinations are evaluated. The zones selected should include the following:

(1) Each type of patient zone having a different type of mobility, density, or attendant ratio, as specified in Worksheet 4.7.2
(2) Each zone that represents a significantly different type of construction, finish, or protection system
(3) Zones containing special medical treatment or support activities (operating suites, intensive care units, laboratories)
(4) Zones not involving housing, treatment, or customary access for four or more inpatients simultaneously who are incapable of self-preservation; such zones should be evaluated as follows:

    (a) Any zone, whether or not used for patient egress, shall be permitted to be evaluated on the same basis as a patient use zone. In such case, the value of factor *F* in Worksheet 4.7.3 shall be assigned the value of factor *L* ("Zone Location") from Worksheet 4.7.2. In such cases, Safety Parameter 10, "Emergency Movement Routes," from Worksheet 4.7.6 shall be graded "deficient" if the exit capacity is less than that prescribed for the actual occupancy of the space and "<2 routes" if less than 75 percent of the prescribed exit capacity is present.
    (b) If the zone is separated by 2-hour fire-rated construction from all patient use zones (including any members that bear the load of a patient use zone) and if any communicating openings through the 2-hour fire-rated construction are protected by 1½-hour fire protection–rated fire doors, the zone shall be permitted to be excluded from evaluation. In such case, that space shall conform with the portion of the *Life Safety Code* appropriate to its use. In addition, appropriate charges under Safety Parameter 8, "Hazardous Areas," in Worksheet 4.7.6 shall be charged against other zones in the facility.
    (c) Evaluation of any unoccupied story or stories located above the highest floor used for health care occupancy is not required, provided each such unoccupied story meets the construction requirements of 18.1.6 (NFPA *101*) for new buildings or 19.1.6 (NFPA *101*) for existing buildings, or if each unoccupied story is protected by automatic sprinklers.

(5) Patient sleeping rooms or suites exceeding 1000 ft^2 (92.9 m^2) of floor area should be evaluated as follows:

    (a) If the room or suite has a single exit access door, it should be evaluated as a single dead-end zone.
    (b) A patient sleeping room or suite of sleeping rooms exceeding the 5000 ft^2 (460 m^2) limitation of 19.2.5.7.2.3(A) (NFPA *101*) should be evaluated as a separate zone that is not a suite.
    (c) A patient sleeping room or suite of sleeping rooms exceeding the 7500 ft^2 (700 m^2) limitation of 18.2.5.7.2.3(B) or 19.2.5.7.2.3(B) (NFPA *101*) should be evaluated as a separate zone that is not a suite.
    (d) A patient sleeping room or suite of sleeping rooms exceeding the 10,000 ft^2 (930 m^2) limitation of 18.2.5.7.2.3(C) or 19.2.5.7.2.3(C) (NFPA *101*) should be evaluated as a separate zone that is not a suite.

(6) Patient care nonsleeping rooms or suites exceeding 2500 ft^2 (230 m^2) of floor area should be evaluated as follows:

    (a) If the room or suite has a single exit access door, it should be evaluated as a single dead-end zone.
    (b) A patient care nonsleeping room or suite of nonsleeping rooms exceeding the 10,000 ft^2 (930 m^2) limitation of 19.2.5.7.3.2 (NFPA *101*) should be evaluated as a separate zone that is not a suite.
    (c) A patient care nonsleeping room or suite of nonsleeping rooms exceeding the 12,500 ft^2 (1160 m^2) limitation of 18.2.5.7.3.2(A) or 19.2.5.7.3.2(A) (NFPA *101*) should be evaluated as a separate zone that is not a suite.
    (d) A patient care nonsleeping room or suite of nonsleeping rooms exceeding the 15,000 ft^2 (1390 m^2) limitation of 18.2.5.7.3.2(B) or 19.2.5.7.3.2(B) (NFPA *101*) should be evaluated as a separate zone that is not a suite.

4.4 Maintenance. Any protection system, requirement, or arrangement that is not maintained in a dependable operating condition or that is used in such a manner that the intended fire safety function or hazard constraint is impaired should be considered defective and receive no credit in the evaluation.

4.5 Occupancy Risk (Worksheet 4.7.2). In establishing a system for evaluating occupancy risk, the following facts are recognized:

(1) There is a basic level of risk inherent in every health care facility.
(2) The fuel characteristics of furniture, equipment, and supplies vary with time.
(3) The arrangement of these items within the space available can vary with time.
(4) Consequently, these three factors are not included as parameters in a safety equivalency measurement; to account for these factors, the occupancy risk baseline is set at the inherent risk level, with the presumption that the furniture, equipment, and supplies are the most combustible and adversely located (from a fire safety standpoint) of those items normally found in health care facilities.

4.5.1 Patient Mobility.

4.5.1.1 The single most important factor controlling risk in a health care facility is the degree to which patients need assistance in taking the actions necessary for their safety. The level of capability in health care facilities varies from patients who, if informed or directed, are able to take positive, self-protecting actions to those patients who have no ability to move or even to take the simplest actions to safeguard themselves. In some cases, patients are directly connected to a fixed life-support system and are so dependent on it that, regardless of their physical condition or the availability of assistance, they cannot be moved without jeopardy of death or serious harm. In the measurement of occupancy risk factors, the least mobile category of patient expected in the zone determines the risk factor for that zone. The rationale for this approach is that, if a zone accepts any patient with a reduced mobility status, it might accept other such patients at any time. The impact of this approach is that most health care facilities should be rated in the "not mobile" risk category. Mobility status should be based on the minimum level of mobility in an average 24-hour period.

4.5.1.2 Mobility Status Factor. Patient mobility status is based on the capability of each patient to take actions necessary for self-protection. The four classes are defined as follows:

(1) *Mobile.* Capable of readily rising from bed and taking self-protecting actions at approximately the same rate as a healthy adult. To be classified as mobile, the patient must not need assistance in getting out of bed and must be able to open a closed or locked door. Persons shall be considered to be mobile if they are not restrained or in any other way limited in response capabilities so that the type of arousal mechanism that normally would awaken an adult is not effective.
(2) *Limited Mobility.* Those patients who have all of the capabilities of a mobile person except that their rate of travel is significantly slower.
(3) *Not Mobile.* Patients incapable of removing themselves from danger exclusively by their own efforts. Examples include persons who are totally bedridden; who need assistance getting out of bed or moving; and who are restrained, locked in their rooms, or otherwise prevented from taking complete emergency self-protection evacuation actions without assistance.
(4) *Not Movable.* Patients not capable of being moved from the room in which they are housed during the course of a fire. Examples include patients attached to life-support systems or involved in medical or surgical procedures that prohibit their immediate relocation without extreme danger of death or serious harm.

4.5.2 Patient Density.

4.5.2.1 The occupancy risk evaluation for occupancy density (number of patients within the zone) measures both the inherent increase in the maximum fire death potential that occurs as the number of patients in a zone increases and the problems involved for a limited staff in handling larger numbers of patients during an emergency.

4.5.2.2 Patient Factor. The density of patients is the number of patients who could potentially be housed in the zone. The patient count should be based on the number of assignable beds in the zone, assuming that they might all be occupied at the time of the fire emergency.

4.5.3 Zone Location.

4.5.3.1 This risk factor relates to fire department accessibility to a fire. The rating system recognizes the inherent advantages for the first story zone. It also recognizes the problems of evacuation from higher stories and the virtual impossibility of using external fire-fighting efforts above the sixth story in any building.

4.5.3.2 Story Factor. The measured zone's location shall be considered to be on the first story if the story has direct access to the exterior at or within less than one-half story height above or below grade. If a building is on a sloping grade, each story that has such exterior access shall be considered as a first story for the purpose of measuring fire zones on those stories. The measured zone shall be considered to be on the second to third story range and the fourth to sixth story range, based on the height of the zone above the nearest at-grade story. The zone shall be considered to be above the sixth story if it is more than six stories above the nearest at-grade story. The risk factor value for zones in basements is the same as for zones at or above the seventh story. The problems involved in emergency internal access, in fire fighting and rescue, and in the inability to make external attack in basements are approximately equivalent to those in the upper stories of buildings.

4.5.4 Ratio of Patients to Attendants.

4.5.4.1 This risk factor recognizes the importance to patient safety of a staff that is immediately available to respond in an emergency. The emergency actions that might be undertaken by the staff include detection, alarm, fire extinguishment, confinement of the fire, establishment of barriers between the patients and the fire (closing patient room doors), rescue, emergency medical aid, and other related functions. A few of these functions, such as detection and alarming, might not be critically related to the ratio of nursing staff to patients, while those related to rescue and the closing of patient room doors have a strong relationship to the staffing ratio. The staff ratio considered is based on the minimum staffing level immediately available (normally the night shift).

4.5.4.2 Patient–Attendant Factor. The ratio of patients to attendants is based on those patients in the fire/smoke zone and the immediately available attendant staff.

4.5.4.2.1 The ratio calculation shall be based on the minimum staffing level (usually occurring during the night shift). Where nursing stations or other positions of attendants are located at the junction of two or more zones and the location of the station is such that each of the zones has immediate access and is in view of the nursing station, the total staffing assigned to the nursing station can be credited to each of the zones. An exception occurs when staff members are bound by duty assignments (cardiac care units, infant nurseries, operating suites, etc.) that prevent them from responding to other than their assigned zone.

4.5.4.2.2 The evaluation system assesses this risk factor at 4.0 in any case involving periods where no attendants are immediately available to a zone that houses patients but where attendants are available within one story of all stories housing patients. This evaluation system is not intended to be used in cases where no staff are present in the building housing patients.

4.5.5 Patient Average Age.

4.5.5.1 This risk factor recognizes the increased susceptibility of the elderly and of infants up to one year old to physical harm by smoke particles, gaseous combustion products, and heated air. A larger risk factor is assigned to zones occupied by a population whose average age is above 65 years or below one year. Basically, imposition of this rating demands additional safety protection in nursing homes for the aged and in nurseries.

4.5.5.2 The mode value is used to arrive at the age factor for the patients in the zone. The calculation should be based on the past record of occupants assigned to the zone. Patients under one year old are classified at the same risk level as those over 65. This factor recognizes the susceptibility of infants to fire.

4.6 Safety Parameters (Worksheet 4.7.6). Safety parameters are a measure of those building factors that bear on or contribute to the safety of those persons (patients, staff, visitors, others) who might be in the particular zone at the time of a fire. Each of the safety parameters was analyzed. Where the current *Life Safety Code* requirements recognize several different approaches to the parameter, the most important alternatives were specified. Also specified were conditions likely to be encountered in situations failing to meet the explicit *Code* requirements and conditions exceeding those required by the *Code*, but available for increased protection.

4.6.1 Construction. Construction types are classified in accordance with the definitions of NFPA 220. Major revisions have been made in the categories and definitions in the recent editions of NFPA 220. Previously, NFPA 220 included requirements for "interior partitions enclosing stairs or other openings through floors." The current edition does not. This change is fully accounted for in this system. *(See 4.6.7.)*

4.6.1.1 Where the facility includes additions or connected structures of different construction, the rating and classification of the structure shall be based on one of the following:

(1) Separate buildings, if in accordance with 8.2.1.3 (NFPA *101*)
(2) Separate buildings, if the additions and connected structure conform to the provisions of applicable sections of Chapter 18 or 19 (NFPA *101*), whether or not separation is provided
(3) The lower safety parameter point score involved, if neither 4.6.1.1(1) nor 4.6.1.1(2) applies

4.6.1.2 The story used to determine the parameter value is the story of the fire/smoke zone being evaluated. The construction type of the building for all stories is based on the lowest construction type anywhere in the building. The story or zone is specified relative to, and beginning with, the level of exit discharge as defined in Section 3.3 (NFPA *101*).

4.6.1.3 Where the zone is on a story below the level of exit discharge, the construction value shall be based on the distance of that story from the level of exit discharge (i.e., one story below the level of exit discharge equals "second"; two stories below the level of exit discharge equals "third"; three or more stories below the level of exit discharge equals "fourth and above").

4.6.2 Interior Finish (Corridor and Exits). The classification of interior finish materials shall be in accordance with Section 10.2 (NFPA *101*). The flame-spread classification shall be based on the most combustible surface after deleting trim. No allowance is made in the safety parameter values for interior finish materials that fail to be classified as a minimum of Class C. It is not anticipated that such materials will be used in health care facilities. In the rare case that such high flame-spread interior finish materials are involved, an individual fire hazard assessment outside the capability of this evaluation system will be required. Interior wall and ceiling finish materials tested in accordance with NFPA 265 or NFPA 286, as permitted by Section 10.2 (NFPA *101*), and meeting the criteria established in Section 10.2 (NFPA *101*) for those test standards, shall be scored as Class A interior finish materials (flame spread ≤25).

4.6.3 Interior Finish (Rooms). See 4.6.2.

4.6.4 Corridor Partitions/Walls. For the purpose of this evaluation, the fire-rated partitions considered are as defined in 18.3.6 (NFPA *101*) for new buildings and 19.3.6 (NFPA *101*) for existing buildings. All elements of the partition, except the door (considered as a separate element in this evaluation), must be included in the determination of its time-rated fire resistance classification according to ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials*. An exception to the general rule of evaluating doors separately from walls occurs where one or more rooms have no doors *(see 4.6.5)*. In this instance, it is considered that the worth of the fire resistance capabilities of the corridor partition wall is so reduced that the wall should be graded as having no fire resistance. *(See Worksheet 4.7.6.)*

4.6.4.1 Corridor partitions shall be graded as "none or incomplete" if they do not meet the requirements of 18.3.6 or 19.3.6 (NFPA *101*), as appropriate, including applicable exceptions. In existing buildings, partitions shall be permitted to be graded as "<½ hour," provided the ceiling within the fire/smoke zone is of a design and construction sufficient to resist the passage of smoke and the partition either extends through or terminates at the underside of the ceiling with a smoketight joint.

4.6.4.2 Corridor partitions shall be graded as "≥½ hour but <1 hour" or "≥1 hour" only where the partitions extend to the underside of the floor or roof construction above in accordance with 18.3.6 or 19.3.6 (NFPA *101*), as appropriate.

4.6.5 Doors to Corridor. The classification of doors and opening protectives to the corridor shall be based on the minimum quality of any door in the zone, and the classification shall be determined in accordance with NFPA 252 or NFPA 257. Doors for protection of vertical openings and hazardous areas that are covered separately in 4.6.7 and 4.6.8 are not included in this evaluation. Doors that do not latch and doors that have louvers shall not be considered in classifying doors to corridors if those doors open to toilet rooms, bathrooms, shower rooms, sink closets, and similar auxiliary spaces that do not contain flammable or combustible materials.

4.6.5.1 No Door. A room shall be considered as not having a door if there is no door or window in the opening or if there is some other mechanism that prevents closing of the door or otherwise leaves a significant opening between the patient room and the corridor. Doors with louvers or ordinary glass lights shall be classified as "no door." (Ordinary glass lights shall not be considered as making a partition incomplete in locations where both sides of the glass light are fully protected by automatic sprinkler systems.) Doors that have been blocked open by door stops, chocks, tiebacks, or other devices that necessitate manual unlatching or releasing action to close the door shall be classified as "no door." Hold-open devices that release when the door is pushed or pulled (such as friction catches or magnetic catches) shall be permitted, and the door shall be classified under 4.6.5.2, 4.6.5.3, and 4.6.5.4. Also, doors that are not provided with a latch in accordance with 18.3.6.3.5 through 18.3.6.3.8 or 19.3.6.3.5 through 19.3.6.3.7 (NFPA *101*) shall be classified as "no door."

4.6.5.2 Doors of Less Than 20-Minute Fire Protection Rating (<20 min FPR). Doors and windows that are not deficient as described in 4.6.5.1 but that do not meet the requirements of 4.6.5.3 shall be classified as less than 20-minute fire protection rating.

4.6.5.3 Doors of 20-Minute or More Fire Protection Rating (≥20 min FPR). Doors and windows shall be considered as having a 20-minute or greater fire protection rating when tested in accordance with 4.6.5,are of 1¾ in. (44 mm) thick, solid, bonded wood core construction, or any other arrangement of equal or greater stability and fire integrity. The thermal insulation capability of the door or window need not be considered. Hollow or sheet steel doors, therefore, meet the 20-minute requirement.

4.6.5.4 Twenty-Minute or More Fire Protection Rating and Automatic Closing (≥20 min FPR and Auto Clos.). Automatic-closing devices shall be considered to be present if the door has an arrangement that holds it open in a manner such that it is released by a smoke detector–operated device (e.g., a magnetic or pneumatic hold-open device) prior to the passage of significant smoke from a room of fire origin into the corridor or from the corridor into a room not involved in the fire. Smoke detectors for operation of such doors shall be permitted to be integral with the door closers, mounted at each opening, or operated from systems meeting the requirements for two or more points of credit under 4.6.12. The requirement for 20-minute fire protection rating is the same as in 4.6.5.3.

4.6.5.5 Self-Closing Patient Room Doors. Traditional self-closing doors on individual patient rooms shall be evaluated in the following manner:

(1) If it can be established that the doors are constantly kept in the normally closed position except when persons are actually passing through the openings, the self-closing device shall be considered as equivalent to an automatic-closing device and credited accordingly.
(2) If the self-closing doors are blocked open, they shall be classified as "no door" and a parameter value of −10 invoked.

4.6.6 Zone Dimensions. Zone dimension shall be as calculated per 18.3.7.1 or 19.3.7.1 (NFPA *101*).

4.6.6.1 The length of a corridor "dead end" shall be measured from the point at which a person egressing from the dead end would have an option of egressing in two separate directions.

4.6.6.2 In assessing the values for this parameter, a single value shall be chosen based on the worst safety level in the zone. For example, if one or more dead ends in excess of 50 ft (15 m) but not more than 100 ft (30 m) exist, the parameter value for dead ends (−4) shall be applied regardless of the actual corridor lengths.

4.6.6.3 Since dead-end corridors and single emergency movement routes *(see 4.6.10)* each confine the occupants of a fire zone to a single means of egress, the effect of these two factors on the parameter value is not cumulative. As indicated by Note b to Worksheet 4.7.6, the parameter value for dead-end corridors is to be 0 instead of either −2, −4, or −6 in the special case where a value of −8 is assessed under 4.6.10 for single emergency movement routes.

4.6.6.4 Zone length applies to the greater dimension of length or width of the zone.

4.6.7 Vertical Openings. These values apply to vertical openings and penetrations, including exit stairways, ramps, and other vertical exits of the type recognized by NFPA *101*, plus pipe shafts, ventilation shafts, duct penetrations, and laundry and incinerator chutes. Enclosures shall be of construction having a fire resistance rating not less than that prescribed for vertical openings *(see Safety Parameter 7 of Worksheet 4.7.6)*. In addition, they shall be equipped with fire doors or acceptable protection of openings into the shafts, all designed and installed to provide a complete barrier to the vertical spread of fire or smoke.

4.6.7.1 A vertical opening or penetration shall be considered open if it has any of the following characteristics:

(1) It is unenclosed.
(2) It is enclosed but does not have doors or opening protectives.
(3) It is enclosed but has openings other than doorways.
(4) It is enclosed with cloth, paper, or similar materials without any sustained flame-stopping capabilities.

4.6.7.2 Where vertical openings are located outside the fire/smoke zone and the separation between the zone and the vertical opening is of 1-hour or greater fire resistance rating and is of higher fire resistance rating than the protection of the vertical opening itself (for example, an open shaft separated from the zone by a 2-hour fire resistance–rated partition with 1½-hour fire protection–rated self-closing fire doors), the rating of this factor for the zone being measured shall be based on the higher of the two fire resistance categories. In this example, a safety parameter value of 3 would be given for the 2-hour fire resistance rating. Where this occurs, however, the space with the vertical opening cannot be considered an exit route or refuge area for that zone when evaluating the emergency movement route parameter addressed in 4.6.10.

4.6.7.3 A vertical opening shall be considered open for more than three stories if there is unprotected penetration of four or more stories on the same shaft without an intervening slab or other cutoff *(also see same area as an unprotected penetration in 4.6.13)*. If a shaft is enclosed at all stories except one and this results in an unprotected opening between the shaft and one, and only one, fire/smoke zone, the parameter value assigned for that shaft opening in the fire/smoke zone where the unprotected opening occurs shall be 0.

4.6.8 Hazardous Areas. Hazardous area protection is determined in accordance with Section 8.7 (NFPA *101*). The term *adjacent zone* as used in the evaluation form means any zone, either on the same story or on the story immediately below, that physically abuts the zone being evaluated and not separated by 2-hour fire resistance–rated construction. The term *outside zone* as used in the evaluation form means any place within the building other than the fire/smoke zone being measured and not separated by 2-hour fire resistance–rated construction.

4.6.8.1 In assessing the parameter value for hazardous areas, only one value shall be chosen. It shall be the most severe value corresponding to the deficiencies present. A double deficiency can exist only where the hazard is severe and the space is not sprinkler protected. Double protection consists of both a fire-rated enclosure and automatic sprinkler protection of the hazardous area. If both of these protections are lacking in a severe hazardous location, the double deficiency value shall be chosen. If double deficiencies exist both within the zone and outside the zone, the higher value (−11) for the condition inside the zone shall be chosen. The values are not cumulative, regardless of how many hazardous areas are present. Table 4.6.8.1 provides a matrix to be used to determine degree of deficiency to be assessed.

Table 4.6.8.1 Hazardous Areas Deficiencies

	Hazard	
Protection	**Severe**	**Not Severe**
None	Double	Single
Fire resistance–rated enclosures	Single	None
Automatic sprinklers and smoke partitions	Single	None
Automatic sprinklers and fire resistance–rated enclosures	None	None

4.6.8.2 Where the hazard is not severe, the maximum deficiency that can occur is a single deficiency, which shall be permitted to be countered by either of the following means:

(1) A fire resistance–rated enclosure
(2) Automatic extinguishing equipment and enclosure by smoke partitions

4.6.8.3 A single deficiency situation also is considered to exist where a severe hazard is protected by either of the following means, but not by both:

(1) A fire resistance–rated enclosure
(2) Automatic extinguishing equipment and enclosure by smoke partitions

4.6.9 Smoke Control. Smoke control definitions are provided in 4.6.9.1 through 4.6.9.3.

4.6.9.1 No Control. There are no smoke barriers (or horizontal exits) on the story, and there is no mechanical smoke control system.

4.6.9.2 Smoke Barrier Serves Zone. A smoke barrier consists of a partition extending across the entire width of the zone equipped with doors that either are self-closing or are closed upon detection by smoke detectors located at the door arches or other release mechanisms as described in 7.2.1.8 (NFPA *101*). To be credited as a smoke barrier, an existing partition also shall conform with the requirements of 19.3.7.2 through 19.3.7.10 (NFPA *101*). New smoke barriers in either new or existing buildings shall meet the more stringent requirements of 18.3.7.2 through 18.3.7.10 (NFPA *101*). A horizontal exit that also complies with 8.5 (NFPA *101*) will act as a smoke barrier and is credited as both a smoke barrier *(see 4.6.9)* and an emergency movement route *(see 4.6.10)*.

4.6.9.3 Mechanically Assisted Systems — by Zone. Mechanically assisted smoke control on a zone basis shall include a smoke barrier, as in 4.6.9.2, supported by a tested and accepted smoke control system that obstructs the leakage of smoke between zones. One method of judging the acceptability of smoke control systems is found in NFPA 92.

4.6.10 Emergency Movement Routes. A movement route is any means of egress meeting the requirements for such means specified in 7.2.2 through 7.2.6 (NFPA *101*). Horizontal exits also shall meet the requirements specified in 4.6.10.4. Doors exiting directly to the exterior also shall constitute a movement route from the room containing such a door.

4.6.10.1 Fewer Than Two Routes. The means of emergency movement from a zone is classified as fewer than two routes if there are not at least two remote movement routes serving the zone. Movement routes shall be permitted to be outside the physical limits of the zone.

4.6.10.2 Multiple Routes. The emergency movement route is multiple if the zone occupants have the choice of two or more distinctly separated movement routes from the zone.

4.6.10.3 Deficient. The choice of parameter value for deficient emergency movement routes is independent of any values determined in 4.6.7.

4.6.10.3.1 An emergency movement route of a type described by 18.2.2 or 19.2.2 (NFPA *101*) is deficient if the door widths or corridor widths do not conform to the requirements of 18.2.3 or 19.2.3 (NFPA *101*).

4.6.10.3.2 Emergency movement routes also shall be considered deficient if they fail to meet the requirements of 18.2.1 through 18.2.7 or 19.2.1 through 19.2.7 (NFPA *101*) for the egress route involved. However, any route where the doors from rooms or through partitions or walls are less than 32 in. (810 mm) in the clear, the corridor(s) involved is less than 34 in. (865 mm) wide, or stair access is less than 28 in. (710 mm) in the clear shall not be credited as an egress route.

4.6.10.3.3 Emergency movement routes shall be considered deficient if the route does not otherwise conform to the requirements of Section 7.1 through 7.2.6 (NFPA *101*), even if the routes have been or are acceptable to the authority having jurisdiction.

4.6.10.3.4 Emergency movement routes shall be considered deficient if the capacity of the exits serving the story containing the zone being evaluated is insufficient for the calculated occupant load of the story. For buildings not protected throughout by automatic sprinklers, use the capacity factor of 0.6 in. (15 mm) per person for stairs.

4.6.10.4 Horizontal Exits. The presence of a single horizontal exit from the zone being evaluated shall be assigned a parameter value of 1, provided the space on the opposite side of the horizontal exit is capable of handling all of the patients from affected zones.

4.6.10.4.1 To be credited as a horizontal exit, the existing arrangement also shall conform with the requirements of 19.2.2.5 (NFPA *101*). New horizontal exits in new or existing buildings shall meet the more stringent requirements of 18.2.2.5 (NFPA *101*).

4.6.10.4.2 To receive credit for horizontal exits, the zone credited shall conform to the requirements of 7.5.1.1 through 7.5.1.1.4 (NFPA *101*) with the zone served considered a separate portion of the building.

4.6.10.4.3 To receive credit for horizontal exits, the travel distance from within each patient sleeping or treatment room in the zone to a horizontal exit door or exit to grade shall not exceed 150 ft (46 m) or where Parameter 13 is scored as 10 shall not exceed 200 ft (61 m).

4.6.10.5 Direct Exits. To be credited for direct exits, each patient-use space (except bathrooms, restrooms, and corridors) in the zone shall have a door that is operable by the room occupant(s) and opens directly to the exterior at grade or onto an exterior balcony with direct access to an exterior exit or a smokeproof enclosure. The direct exit shall be ramped or otherwise without steps or changes in elevation that could prevent or obstruct the movement of wheelchairs or wheellittered patients through the direct exits to a place of safety and refuge.

4.6.11 Manual Fire Alarm. The manual alarm systems for new construction shall be in accordance with the requirements of 18.3.4 other than 18.3.4.3.2 (NFPA *101*). Existing construction shall be in accordance with 19.3.4 other than 19.3.4.3.2 (NFPA *101*). Connection to the fire department shall be considered as being met if the fire alarm system is connected directly to the fire department through an approved central station or through other means acceptable to the authority having jurisdiction.

4.6.12 Smoke Detection and Alarm. A detection system as used herein is one based on the use of automatic smoke detectors installed in accordance with Section 9.6 (NFPA *101*). Notification shall be in accordance with 18.3.4.3 other than 18.3.4.3.2 or 19.3.4.3 other than 19.3.4.3.2 (NFPA *101*). No recognition is given for thermal detectors; however, credit is given for the use of quick-response sprinklers per Note g of Worksheet 4.7.6. The detection system categories are described in 4.6.12.1 through 4.6.12.5.

4.6.12.1 None. There are no smoke detectors in the zone, or, if present, they are not included in any of the categories of 4.6.12.2 through 4.6.12.5.

4.6.12.2 Corridor Only. Smoke detectors are installed throughout the corridors of the zone involved in accordance with Section 9.6 (NFPA *101*).

4.6.12.3 Rooms Only. Smoke detectors are installed throughout the rooms of the zone involved. These smoke detectors shall be considered as meeting this requirement where there is at least one smoke detector in each room occupied or used by patients. Detectors are not required in restrooms or closets.

4.6.12.4 Corridor and Habitable Spaces. Detection systems installed throughout the corridors of the zone involved and in the habitable spaces (patient rooms, nurses stations, and other areas basically used for human occupancy) shall be considered as meeting the requirements for a corridor and habitable spaces detection system. Closets, toilet rooms, and other auxiliary spaces, as well as ceiling voids, interstitials, and other building spaces not used by humans as a normal part of their regular occupancy, are not required to have detectors.

4.6.12.5 Total Spaces in Zone. Total space provision of detectors includes detector coverage of all spaces, except noncombustible building voids that contain no combustible materials. The total space credit is to be given if the zone measured meets this criterion, regardless of the presence or lack of detectors in other portions of the building.

4.6.13 Automatic Sprinklers.

4.6.13.1 Wherever sprinkler protection is involved in an area having an unprotected vertical opening, the sprinkler protection around that vertical opening shall conform to Chapter 8 (NFPA *101*). This protection is required to allow the credit for sprinkler protection but shall in no way reduce any assessed value under Safety Parameter 7 in Worksheet 4.7.6 resulting from an unprotected vertical opening.

4.6.13.2 In Worksheet 4.7.7, the value for sprinkler protection credited to the people movement safety (S_3) category is divided by 2. This produces a safety parameter value of only one-half the value credited in other categories.

4.6.13.3 Each sprinkler system shall be provided with supervision. Each sprinkler system shall be interconnected electrically with the fire alarm system, and sprinkler control valves shall be supervised electrically so that at least a local alarm shall sound in a constantly attended location when a valve is not in the fully open position.

4.6.13.4 In evaluating sprinkler protection within the zone, the protection or lack of protection of hazardous areas is considered separately and covered under 4.6.8. For all other areas in the zone, sprinklers shall be graded based on the categories specified in 4.6.13.4.1 through 4.6.13.4.3.

4.6.13.4.1 None. No credit is applied if there are no sprinklers or if sprinklers, though present, are not sufficient to qualify for one of the other categories specified.

4.6.13.4.2 Corridor and Habitable Space. Habitable space includes patient rooms, nurses' stations, and other areas used basically for human occupancy. Habitable space does not include closets, bathrooms, toilets, elevators, and similar spaces. This safety parameter value is based on standard sprinkler spacings in the areas covered and is conditional, based on the classification of construction type as covered in 4.6.1.

4.6.13.4.2.1 Safety Parameter 1, "Construction" *(see 4.6.1)*, in Worksheet 4.7.6 is based on a "protected" or "fire-resistive" type of construction. Protected or fire-resistive types of construction include Types I, II(222), II(111), III(211), and V(111). This credit is based on a system that effectively provides coverage for all corridor and habitable space in the zone, plus the establishment of water distribution patterns or other protection in a manner to prevent the advance of fire from nonsprinklered spaces into the sprinklered spaces. In buildings of protected or fire-resistive construction, the credit is to be applied to any zone where these conditions are met, whether or not areas outside the zone are protected similarly.

4.6.13.4.2.2 Safety Parameter 1, "Construction" *(see 4.6.1)*, is based on an "unprotected" type of construction. Unprotected types of construction include Types II(000), III(200), and V(000). In any unprotected type of construction, the credit for corridor and habitable space protection is to be given only if, in addition to the conditions described in 4.6.13.4.2.1, sprinkler protection also is provided in all spaces in the building (including attic or loft spaces) with construction elements that are not sheathed, enclosed, or otherwise protected with fire-resistive materials such as gypsum board, plaster, or masonry block.

4.6.13.4.3 Entire Building. Total space automatic sprinkler protection is to be credited only if the entire structure is protected by automatic sprinklers in accordance with 18.3.5 or 19.3.5 (NFPA *101*). This credit also is given where a smoke zone in an existing hospital is renovated to install quick-response or residential sprinklers in accordance with 18.1.1.4.3 (NFPA *101*); however, the mandatory safety requirements values of Worksheet 4.7.8C for nonsprinklered existing hospitals must be used. Wherever quick-response automatic sprinklers are provided for zones as part of the entire building sprinkler system, additional credit shall be permitted to be taken under Safety Parameter 12, "Smoke Detection and Alarm." *(See 4.6.12 and Worksheet 4.7.6.)*

4.7 Worksheets for Evaluating Fire/Smoke Zones. The worksheets for evaluating fire/smoke zones use a 10-step process found in Figure 4.7.

WORKSHEET 4.7.1 COVER SHEET

Fire/Smoke Zone* Evaluation Worksheet for Health Care Facilities

Facility ______________________ Building ______________________

Zone(s) evaluated ______________________

Evaluator ______________________ Date ______________________

Complete this worksheet for each zone. Where conditions are the same in several zones, one worksheet can be used for those zones.

*Fire/smoke zone is a space separated from all other spaces by floors, horizontal exits, or smoke barriers.

WORKSHEET 4.7.2 OCCUPANCY RISK PARAMETER FACTORS

Risk Parameters	Risk Factor Values					
1. Patient Mobility (M)	Mobility Status	Mobile	Limited Mobility		Not Mobile	Not Movable
	Risk Factor	1.0	1.6		3.2	4.5
2. Patient Density (D)	No. of Patients	1–5	6–10		11–30	>30
	Risk Factor	1.0	1.2		1.5	2.0
3. Zone Location (L)	Story	1st	2nd or 3rd	4th to 6th	7th and Above	Basements
	Risk Factor	1.1	1.2	1.4	1.6	1.6
4. Ratio of Patients to Attendants (T)	$\frac{\text{Patients}}{\text{Attendant}}$	$\frac{1\text{–}2}{1}$	$\frac{3\text{–}5}{1}$	$\frac{6\text{–}10}{1}$	$\frac{>10}{1}$	$\frac{\text{One or More*}}{\text{None}}$
	Risk Factor	1.0	1.1	1.2	1.5	4.0
5. Patient Average Age (A)	Age	<65 Years and >1 Year			≥65 Years or ≤1 Year	
	Risk Factor	1.0			1.2	

*A risk factor of 4.0 is charged to any zone that houses patients without any staff in immediate attendance.

WORKSHEET 4.7.3 OCCUPANCY RISK FACTOR CALCULATION

Occupancy Risk $\underset{M}{\boxed{}} \times \underset{D}{\boxed{}} \times \underset{L}{\boxed{}} \times \underset{T}{\boxed{}} \times \underset{A}{\boxed{}} = \underset{F}{\boxed{}}$

WORKSHEET 4.7.4 ADJUSTED OCCUPANCY RISK FACTOR — NEW BUILDINGS

$1.0 \times \underset{F}{\boxed{}} = \underset{R}{\boxed{}}$

WORKSHEET 4.7.5 ADJUSTED OCCUPANCY RISK FACTOR — EXISTING BUILDINGS

$0.6 \times \underset{F}{\boxed{}} = \underset{R}{\boxed{}}$

(For use with NFPA 101A-2016/NFPA *101*-2015) (p. 1 of 4)

WORKSHEET 4.7.6 SAFETY PARAMETER VALUES

Safety Parameters | **Parameter Values**

1. Construction

Story or Zone	Building Construction Type: V(000)	V(111)	III(200)	III(211), IV(2HH)	II(000)	II(111)	II(222), I(332), I(442)
First	−2	0	−2	0	0	2	2
Second	−7	−2	−4	−2	−2	2	4
Third	−9	−7	−9	−7	−7	2	4
4th and Above	−13	−7	−13	−7	−9	−7	4

Safety Parameters					
2. Interior Finish (Corridors and Exits)	Class C	Class B	Class A		
	−5(0)[f]	0(3)[f]	3		
3. Interior Finish (Rooms)	Class C	Class B	Class A		
	−3(1)[f]	1(3)[f]	3		
4. Corridor Partitions/Walls	None or Incomplete	<½ hr	≥½ hr to <1 hr	≥1 hr	
	−10(0)[a]	0	1(0)[a]	2(0)[a]	
5. Doors to Corridor	No Door	<20 min FPR	≥20 min FPR	≥20 min FPR and Auto Clos.	
	−10	0	1(0)[d]	2(0)[d]	

6. Zone Dimensions

Dead End: >100 ft	Dead End: >50 ft to 100 ft	Dead End: 30 ft to 50 ft	No Dead Ends >30 ft and Zone Length Is: >150 ft	No Dead Ends >30 ft and Zone Length Is: 100 ft to 150 ft	No Dead Ends >30 ft and Zone Length Is: <100 ft
−6(0)[b]	−4(0)[b]	−2(0)[b]	−2(0)[c](0)[h]	0(0)[h]	1

7. Vertical Openings

Open 4 or More Stories	Open 2 or 3 Stories	Enclosed with Indicated Fire Resist.: <1 hr	Enclosed with Indicated Fire Resist.: ≥1 hr to <2 hr	Enclosed with Indicated Fire Resist.: ≥2 hr
−14	−10	0	2(0)[e]	3(0)[e]

8. Hazardous Areas

Double Deficiency: In Zone	Double Deficiency: Outside Zone	Single Deficiency: In Zone	Single Deficiency: In Adjacent Zone	No Deficiencies
−11	−5	−6	−2	0

9. Smoke Control

No Control	Smoke Barrier Serves Zone	Mech. Assisted Systems by Zone
−5(0)[c]	0	3

10. Emergency Movement Routes

<2 Routes	Multiple Routes: Deficient	Multiple Routes: W/O Horizontal Exit(s)	Multiple Routes: Horizontal Exit(s)	Direct Exit(s)
−8	−2	0	1	5

11. Manual Fire Alarm

No Manual Fire Alarm	Manual Fire Alarm: W/O F.D. Conn.	Manual Fire Alarm: W/ F.D. Conn.
−4	1	2

12. Smoke Detection and Alarm

None	Corridor Only	Rooms Only	Corridor and Habit. Spaces	Total Spaces in Zone
0(3)[g]	2(3)[g]	3(3)[g]	4	5

13. Automatic Sprinklers

None	Corridor and Habit. Space	Entire Building
0	8	10

[a] Use (0) where Parameter 5 is −10.

[b] Use (0) where Parameter 10 is −8.

[c] Use (0) on story with fewer than 31 patients (existing buildings only).

[d] Use (0) where Parameter 4 is −10.

[e] Use (0) where Parameter 1 is based on first story zone or on an unprotected type of construction (columns marked “000” or “200”).

For SI units, 1 ft = 0.3048 m; 1 ft² = 0.092 m².

[f] Use ( ) if the area of Class B or C interior finish in the corridor and exit or room is protected by automatic sprinklers and Parameter 13 is 0; use ( ) if the room with existing Class C interior finish is protected by automatic sprinklers, Parameter 4 is greater than or equal to 1, and Parameter 13 is 0.

[g] Use this value in addition to Parameter 13 if the entire zone is protected with quick-response automatic sprinklers.

[h] Use (0) where zone area does not exceed limitations of 18.3.7.1 or 19.3.7.1 (NFPA *101*) and distance from any point to reach a door in smoke barrier ≤200 ft.

(For use with NFPA 101A-2016/NFPA *101*-2015) (p. 2 of 4)

FIGURE 4.7 ***Continued***

WORKSHEET 4.7.10 FACILITY FIRE SAFETY REQUIREMENTS WORKSHEET

Complete one copy of this worksheet for each facility.
For each consideration, select and mark the appropriate column.

		Met	Not Met	Not Applic.
A.	Building utilities conform to the requirements of Section 9.1.			X
B.	In new facilities only, life-support systems, alarms, emergency communication systems, and illumination of generator set locations are powered as prescribed by 18.5.1.2 and 18.5.1.3.			
C.	Heating and air conditioning systems conform with the air conditioning, heating, and ventilating systems requirements within Section 9.2, except for enclosure of vertical openings, which have been considered in Safety Parameter 7 of Worksheet 4.7.6.			X
D.	Fuel-burning space heaters and portable electrical space heaters are not used.			X
E.	There are no flue-fed incinerators.			
F.	An evacuation plan is provided and fire drills conducted in accordance with 18.7.1/18.7.2 and 19.7.1/19.7.2.			X
G.	Smoking regulations have been adopted and implemented in accordance with 18.7.4 and 19.7.4.			X
H.	Combustibility of draperies, upholstered furniture, mattresses, furnishings, and decorations is limited in accordance with 18.7.5 and 19.7.5.			
I.	Fire extinguishers are provided in accordance with the requirements of 18.3.5.12 and 19.3.5.12.			X
J.	Exit signs are provided in accordance with the requirements of 18.2.10.1 and 19.2.10.1.			
K.	Emergency lighting is provided in accordance with 18.2.9.1 or 19.2.9.1.			
L.	Standpipes are provided in all new high-rise buildings as required by 18.4.2.			

All references are to NFPA *101*, *Life Safety Code.*

WORKSHEET 4.7.11 CONCLUSIONS

1. ☐ All of the checks in Worksheet 4.7.9 are in the “Yes” column and all applicable considerations in Worksheet 4.7.10 are identified as “Met”. The level of fire safety is at least equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for health care occupancies.

2. ☐ All of the checks in Worksheet 4.7.9 are in the “Yes” column and all considerations identified in Worksheet 4.7.10 as “Not Met” have been evaluated and mitigated to the satisfaction of the AHJ. The level of fire safety is at least equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for health care occupancies.

3. ☐ One or more of the checks in Worksheet 4.7.9 are in the “No” column or any consideration identified in Worksheet 4.7.10 as “Not Met” has NOT been evaluated and mitigated to the satisfaction of the AHJ. The level of fire safety is not shown by this system to be equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for health care occupancies.

(For use with NFPA 101A-2016/NFPA *101*-2015) (p. 4 of 4)

FIGURE 4.7 ***Continued***

4.7.1 Step 1 — Complete the Cover Sheet Using Worksheet 4.7.1. See Figure 4.7.

4.7.2 Step 2 — Determine Occupancy Risk Parameter Factors Using Worksheet 4.7.2. For each risk parameter in Worksheet 4.7.2, select and circle the appropriate risk factor value. Choose only one value for each of the five risk parameters.

4.7.3 Step 3 — Compute Occupancy Risk Factor *F* Using Worksheet 4.7.3. The following steps should be taken:

(1) Transfer the circled risk factor values from Worksheet 4.7.2 to the corresponding blocks in Worksheet 4.7.3.
(2) Compute occupancy risk factor *F* by multiplying the risk factor values as indicated in Worksheet 4.7.3.

4.7.4 Step 4 — Compute Adjusted Occupancy Risk Factor *R* Using Worksheet 4.7.4 or Worksheet 4.7.5. The following steps should be taken:

(1) If building is classified as "new," use Worksheet 4.7.4. If building is classified as "existing," use Worksheet 4.7.5.
(2) Transfer the value of *F* from Worksheet 4.7.3 to Worksheet 4.7.4 or Worksheet 4.7.5, as appropriate. Calculate *R*.
(3) Transfer *R* to the block labeled *R* in Worksheet 4.7.9.

4.7.5 Step 5 — Determine Safety Parameter Values Using Worksheet 4.7.6. Select and circle the safety value for each safety parameter in Worksheet 4.7.6 that best describes the conditions in the zone. Choose only one value for each of the 13 parameters. If two or more values appear to apply, choose the one with the lowest point value.

4.7.6 Step 6 — Compute Individual Safety Evaluations Using Worksheet 4.7.7. The following steps should be taken:

(1) Transfer each of the 13 circled safety parameter values from Worksheet 4.7.6 to every available block in the line with the corresponding safety parameter in Worksheet 4.7.7. For Safety Parameter 13, the value entered in the "People Movement Safety" column is recorded in Worksheet 4.7.7 as one-half the corresponding value circled in Worksheet 4.7.6.
(2) Add each of the four columns, keeping in mind that any negative numbers need to be deducted.
(3) Transfer the resulting total values for S_1, S_2, S_3, and S_4 to the corresponding blocks in Worksheet 4.7.9.

4.7.7 Step 7 — Determine Mandatory Safety Requirements Values Using Worksheet 4.7.8A, 4.7.8B, or 4.7.8C as Appropriate. The following steps should be taken:

(1) Using the classification of the building (i.e., new or existing) and the story where the zone is located, circle the appropriate value in each of the three columns in Worksheet 4.7.8A, 4.7.8B, or 4.7.8C.
(2) Transfer the three circled values from Worksheet 4.7.8A, 4.7.8B, or 4.7.8C to the blocks marked S_a, S_b, and S_c in Worksheet 4.7.9.
(3) The mandatory safety requirements values for basements are based on the distance of the basement level from the closest level of discharge. *(See also 4.6.1.2 and 4.6.1.3.)*

4.7.8 Step 8 — Determine Zone Fire Safety Equivalency Using Worksheet 4.7.9. The following steps should be taken:

(1) Perform the subtractions indicated in Worksheet 4.7.9. Enter the differences in the appropriate answer blocks.
(2) For each row, check "yes" if the value in the answer block is zero (0) or greater. Check "no" if the value in the answer block is a negative number.

4.7.9 Step 9 — Evaluate Other Considerations Not Previously Addressed Using Worksheet 4.7.10. The equivalency covered by Worksheets 4.7.2 through 4.7.9 includes the majority of the considerations covered by the *Life Safety Code*. Some considerations are not evaluated by this method and must be considered separately. These additional considerations are covered in Worksheet 4.7.10, Facility Fire Safety Requirements Worksheet. Complete one copy of this separate worksheet for each facility.

4.7.10 Step 10 — Determine Equivalency Conclusion. Conclude whether the level of life safety is at least equivalent to that prescribed by the *Life Safety Code* using Worksheet 4.7.11, Conclusions. Worksheet 4.7.11 combines the zone fire safety equivalency evaluation of Worksheet 4.7.9 and the additional considerations of Worksheet 4.7.10.

Chapter 5 Fire Safety Evaluation System for Detention and Correctional Occupancies

5.1 General.

5.1.1 This chapter is part of an NFPA guide and, therefore, is not mandatory. The term *shall* in this chapter is used to indicate that if the provisions of the chapter are applied, the procedures mandated are to be followed to ensure the effectiveness of the evaluation system.

5.1.2 The fire safety evaluation system is a measuring system. It compares the level of safety provided by an arrangement of safeguards that differ from those specified in NFPA *101* to the level of safety provided in a building that conforms exactly with the details of the *Code*.

5.2 Procedure for Determining Equivalency. Evaluate the entire facility using Figure 5.5, Worksheets for Evaluating Fire Safety in Detention and Correctional Occupancies (Worksheets 5.5.1 through 5.5.8), as defined in Sections 22.1 and 23.1 (NFPA *101*), on a single worksheet. Where different use conditions or fire protection features are involved, portions of the facility separated from each other by 2-hour or greater fire resistance–rated construction (including any members that bear the load of detention use, egress, or refuge space and with 1½-hour fire protection–rated doors in any communication opening) shall be permitted to be evaluated separately.

5.3 Maintenance. Any protection system, requirement, arrangement, or procedure that is not maintained in a dependable operating condition, is used in such a manner that the intended fire safety function or hazard constraint is impaired, or is not in a sufficient state of readiness should be considered defective and should receive no credit in the evaluation.

5.4 Safety Parameters (Worksheet 5.5.3). The safety parameters are a measure of those building factors that bear upon or contribute to the safety of those persons who might be in the building at the time of a fire. *(See Worksheet 5.5.3.)* Each of the safety parameters is to be analyzed, and the safety value for each parameter that best describes the condition in the building is to be identified. Only one value for each of the parameters is to be chosen. If two or more values appear to apply, the one with the lowest point value governs.

5.4.1 Construction. Construction types are defined by the fire resistance and combustibility of load-bearing framing members, floor construction, and roof construction in accordance with NFPA 220, which extracts material from *NFPA 5000*. *(See Table 5.4.1.)*

5.4.1.1 Where the facility includes additions or connected structures of different construction, the rating and classification of the structure shall be based on one of the following:

(1) Separate buildings where a 2-hour or greater fire resistance–rated separation exists between the portions of the building
(2) The lower safety parameter point score involved, where such a separation does not exist

5.4.1.2 The story used to determine the parameter value is the highest story used for confinement purposes. Story height is based on stories starting with the level of exit discharge. Where there are stories below the level of exit discharge, the maximum value assigned to the construction parameter shall be based on a two-story building or the actual story height, whichever is the lower value.

5.4.1.3 A multitiered open cell block in an existing building shall be permitted to be considered a single story, provided that one or more of the following conditions exist:

(1) A smoke control system is provided (*see recommended design criteria in A.23.3.1.3 of* NFPA *101*) to maintain the level of smoke filling from potential cell fires at least 5 ft (1525 mm) above the floor level of any occupied tier.
(2) A smoke control system as described in 5.4.1.3(1) is provided to maintain the level of smoke filling at least 5 ft (1525 mm) above the exit level where either of the following situations exist:
    (a) The cell block is Use Condition II.

Table 5.4.1 Fire Resistance Ratings for Type I Through Type V Construction (hours)

H: Heavy timber members *(see NFPA 5000 for requirements)*.
[a]See 7.3.2.1 of *NFPA 5000*.
[b]See Section 7.3 of *NFPA 5000*.
[c]See 7.2.3.2.12, 7.2.4.2.3, and 7.2.5.6.8 of *NFPA 5000*.
[**5000:** Table 7.2.1.1]

(b) The cell block is Use Condition III, and all persons housed in the cell block can pass through a free access smoke barrier or freely pass below the calculated smoke level with not more than 50 ft (15 m) of travel from their cell.

(3) Complete automatic sprinkler protection is provided.

5.4.2 Hazardous Areas.

5.4.2.1 The assignment of charges for hazardous areas is a four-step process.

5.4.2.1.1 Step 1 — Identify Hazardous Areas. Hazardous areas are defined in 22.3.2 and 23.3.2 (NFPA *101*).

5.4.2.1.2 Step 2 — Determine the Level of Hazard. A hazardous area is classed as severe if it is an area requiring both automatic sprinkler protection and fire-rated enclosure per 22.3.2.1 (and 22.3.5.2) or 23.3.2.1 (NFPA *101*).

5.4.2.1.3 Step 3 — Determine the Fire Protection Provided. The parameter value for hazardous areas is based on the presence or absence of the fire protection necessary to control or confine the hazard. Two levels of fire protection are considered. The first consists of automatic sprinklers or other appropriate extinguishing system covering the entire hazard. The second is based on fire resistance–rated enclosures, including any bearing members in the space, partitions separating the hazardous area from all other spaces, and doors to the space sufficient to exceed the potential of the fire load involved. Any hazardous space that has either protection system is classified as having single protection. Any hazardous space that is both fully enclosed in a capable fire resistance–rated enclosure and sprinklered is classified as having double-level protection. On this basis, any fuel load that has the potential to overwhelm the available structural capability of both its own enclosure and the basic structure could, as a maximum, have single protection.

5.4.2.1.4 Step 4 — Determine the Degree of Deficiency and Assign Parameter Values. The parameter value ultimately is determined by the degree of the deficiencies of the hazardous area based on the level of protection needed.

5.4.2.2 Table 5.4.2.2 provides a matrix to be used to determine the degree of deficiency for this parameter. In some situations, more than one hazardous area with the same or differing levels of deficiency can exist. In this case, the choice is based on the single most serious deficiency for the hazardous area.

5.4.3 Fire Alarm. Fire alarms are defined in 5.4.3.1 through 5.4.3.3.

5.4.3.1 No Alarm. There is no fire alarm system, or the system is incomplete and does not meet the requirements for a higher-scored category.

5.4.3.2 Without Fire Department Notification (W/O F.D. Notification). There is a manual fire alarm system or smoke detection system conforming with the appropriate requirements of 22.3.4 or 23.3.4 (NFPA *101*), except that the requirements of 22.3.4.3.2 or 23.3.4.3.2 covering automatic transmission of the alarm to the fire department are not met.

5.4.3.3 With Fire Department Notification (W/ F.D. Notification). There is a manual fire alarm or smoke detection system conforming with the appropriate requirements of 22.3.4 or 23.3.4 (NFPA *101*).

5.4.3.3.1 Without Manual Alarm. There is no manual alarm system, but a smoke detection alarm system or sprinkler system recognized under Safety Parameter 4 or Safety Parameter 5 of this system is provided and is arranged to transmit an alarm automatically to the fire department under either of the following conditions:

(1) Fire resistance and structural strength exceed maximum potential of hazard.
(2) Fire resistance or structural strength is not sufficient to withstand potential of hazard.

5.4.3.3.2 With Manual Alarm. There is a manual alarm system, and it is arranged to transmit an alarm automatically to the fire department.

5.4.4 Smoke Detection.

5.4.4.1 General. A detection system as used herein is one based on the use of smoke detectors meeting the installation requirements of 22.3.4.4 and 23.3.4.4 (NFPA *101*) and *NFPA 72* with the extent of coverage as defined in 5.4.4.2. No credit is given for thermal detectors in habitable spaces.

5.4.4.2 The detection system categories are described in 5.4.4.2.1 through 5.4.4.2.5.

5.4.4.2.1 None. There are no smoke detectors, or, if present, they do not meet the requirements for a higher-scored category.

5.4.4.2.2 Corridors, Common Spaces, and Sleeping Rooms for More Than Four Persons. Smoke detection requirements of such spaces located within the residential housing area are covered by smoke detector installations in accordance with *NFPA 72*. In Use Condition II dormitory rooms in sprinklered buildings where staff is present whenever the dormitory room is occupied, detectors may be omitted from the dormitory room but not from the corridors and common spaces.

5.4.4.2.3 All Sleeping Rooms. Smoke detectors shall be considered as meeting the requirement when there is at least one smoke detector in each sleeping room occupied or used by prisoners. In rooms having a dimension in excess of 30 ft

Table 5.4.2.2 Hazardous Areas — Degree of Deficiency

	No protection	Sprinkler protection	Fire resistance–rated enclosure	Sprinklered and fire resistance–rated enclosure
Hazardous area	Single deficiency	No deficiency		
Severely hazardous area	Double deficiency	Single deficiency	Single deficiency* Double deficiency†	No deficiency* Single deficiency†

*If fire resistance and structural strength exceed maximum potential of hazard.
†If fire resistance and structural strength are not sufficient to withstand potential of hazard.

(9.1 m), additional detectors are provided so that detector spacing does not exceed approximately 30 ft (9.1 m). Detectors are not required in restrooms or closets.

5.4.4.2.4 Full Coverage. The requirements of 5.4.4.2.2 and 5.4.4.2.3 are met.

5.4.4.2.5 Total Building. Total building detector credit requires conformance with the requirements of *NFPA 72* for total coverage.

5.4.5 Automatic Sprinklers.

5.4.5.1 General. In evaluating sprinkler protection, the protection or lack of protection of hazardous areas is considered separately and covered under 5.4.2, except that total building protection shall include hazardous areas. In addition, the existence or lack of fire department notification is considered separately under 5.4.3. In all other situations, any sprinkler installations shall conform to 22.3.5 and 23.3.5 (NFPA *101*) and be graded based on the categories specified in 5.4.5.1.1 through 5.4.5.1.3.

5.4.5.1.1 None. No credit is given if there are no sprinklers or if sprinklers, though present, are not sufficient to qualify for one of the other categories specified.

5.4.5.1.2 Residential Housing Areas. The credit for sprinkler protection of residential housing areas is given for arrangements whereby sprinklers are located throughout the areas, such that all space within such areas (including cells or sleeping rooms) is covered by the protection spray pattern of sprinkler heads.

5.4.5.1.3 Entire Building. The building is totally sprinkler protected in accordance with NFPA 13 for light hazard occupancy (or higher hazard occupancy for any spaces classified as higher hazard by NFPA 13).

5.4.6 Interior Finish.

5.4.6.1 Classification of interior wall and ceiling finish materials is in accordance with Section 10.2 (NFPA *101*).

5.4.6.2 No consideration is included in the safety parameter value for any finish with a flame-spread index greater than 200 as tested by ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials.* Some materials, including foamed plastics, high density polyethylene, and polypropylene, are not permitted to be tested in accordance with ASTM E84 and must be tested in accordance with NFPA 286 and must meet the acceptance criteria shown in 10.2 (NFPA *101*). Some materials, including asphalt-impregnated paper, are capable of inducing extreme rates of fire growth and rapid flashover. In any case involving these materials, the resultant risk is considered to classify any such finish area as a hazardous area to be evaluated under 5.4.2. Note that plywood of ¼ in. (6 mm) or greater thickness should be considered as having a flame-spread index of 200 or less. Interior wall and ceiling finish materials tested in accordance with NFPA 265 or NFPA 286 as permitted by Section 10.2 (NFPA *101*), and meeting the criteria established in Section 10.2 (NFPA *101*) for those test standards, shall be scored as Class A interior finish materials (flame spread ≤25).

5.4.7 Reserved.

5.4.8 Cell/Sleeping Room Enclosure.

5.4.8.1 The parameter value categories for cell or sleeping room enclosures are divided between those for cells or sleeping rooms that face directly onto a corridor and those for which there is an intervening common space (i.e., day room, group activity space, or other space between the sleeping room and the corridor access).

5.4.8.2 Open. The cell or sleeping room enclosure includes an opening in excess of 0.85 ft^2 (0.08 m^2). In Use Condition V, the closure shall be considered "open" if there are any openings exceeding the minimum necessary for door swing and latch, unless either of the following conditions exists:

(1) The affected cells meet the requirements for mechanically assisted smoke control in 5.4.13.3.
(2) There is a closure for such openings operable from inside the cell.

5.4.8.3 Smoke Resistant <1 Hour. An enclosure qualifies in this category if the walls are complete from slab to slab or to a continuous smoke-resistant ceiling, and if doors are complete, but some wall aspect (wall, ceiling, etc.) is less than 1-hour fire resistance–rated, or the door is not capable of resisting fire for at least 20 minutes.

5.4.8.4 One-Hour Fire Resistance–Rated or Greater (≥1-Hour Fire Resistance). An enclosure qualifies in this category if it meets all of the requirements of 5.4.8.3, all wall aspects have at least a 1-hour fire resistance rating, and the door is capable of resisting fire for at least 20 minutes.

5.4.9 Separation of Residential Housing Areas from Other Areas. A residential housing area includes sleeping areas and any contiguous day room, group activity space, or other common space.

5.4.9.1 The parameter value categories for separation of residential housing areas are based on the quality of the common walls, separating partitions, and doors between residential housing areas and the rest of the building. The parameter value is based on the residential housing area that has the lowest quality separation. Where a building contains more than one residential housing area, the separation of residential housing areas from each other also is to be considered equivalent to the separation of a residential housing area from some other type of space. In buildings entirely composed of a single residential housing area, the separation is considered to be fire resistant if there is at least a 30 ft (9.1 m) separation from other structures and smoke resistant if there is a separation of less than 30 ft (9.1 m).

5.4.9.2 Classification of internal separations is based on the criteria in 5.4.9.2.1 through 5.4.9.2.3.

5.4.9.2.1 Incomplete. Any separation that does not meet the criteria for 5.4.9.2.2 or 5.4.9.2.3 is incomplete.

5.4.9.2.2 Smoke-Resistant Less Than 1 Hour. An enclosure qualifies in this category if the walls are complete from slab to slab or to a continuous smoke-resistant ceiling, and if doors are complete, but some wall aspect (wall, ceiling, etc.) is less than 1-hour fire resistance–rated or the door is not capable of resisting fire for at least 20 minutes.

5.4.9.2.3 One-Hour Fire Resistance or Greater (≥1-Hour Fire Resistance). An enclosure qualifies in this category if it meets all of the requirements of 5.4.9.2.2, all wall aspects have at least a 1-hour fire resistance rating, and the door is capable of resisting fire for at least 20 minutes.

5.4.10 Exit System.

5.4.10.1 General. Exit routes are the paths of travel from the residential housing area to outside of any of the types and arrangements described in Chapter 7 (NFPA *101*). The exit route starts at the corridor interface with the cell or common space as indicated by 5.4.8.

5.4.10.2 Multiple Routes. Multiple routes exist where the occupants of any residential housing area have, either from the residential housing area or through access in a corridor adjacent to the residential housing area, a choice of two separate exit routes in accordance with 22.2.4 or 23.2.4 (NFPA *101*) to the outside of the types specified in 22.2.2 and 23.2.2 (NFPA *101*).

5.4.10.3 Deficient. An exit route is deficient if it is usable with reasonable safety but fails to meet any of the applicable criteria in Chapter 7 (NFPA *101*).

5.4.10.4 Direct Room Exits. To be credited with direct room exits, each cell or other sleeping room must have a door that opens to the exterior at grade or to an unenclosed exterior balcony with direct access to an exterior exit or smokeproof enclosure. The locking of such a door must be no more restrictive than that required for the least restrictive exit or smoke barrier door for the use condition involved. In large rooms, the maximum travel distance from any occupiable location to a direct room exit must not exceed 50 ft (15 m). Where the separation of the individual sleeping rooms from other spaces and from each other is smoke resistant, the credit for direct room exits is applicable even if there are no other exit routes from the involved sleeping rooms.

5.4.10.5 No exit shall be considered in this parameter unless the locking arrangement conforms with the criteria for the use condition being applied to the facility.

5.4.11 Exit Access.

5.4.11.1 Exit access is the travel distance from any point in a room to an exit (or to a smoke barrier in an existing building). In addition, any exit arrangement that does not conform with 22.2.6.2 (NFPA *101*) for new buildings or with 23.2.6.2 (NFPA *101*) for existing buildings shall receive a parameter value no higher than the score for egress travel [i.e., >150 ft (>45 m) and ≤200 ft (≤61 m)].

5.4.11.2 The penalty for dead-end access shall be assessed where any corridor affords access in only one direction to a required exit from that corridor. The calculation of the distance to determine the parameter value is the measurement from the centerline of the doorway exiting to the corridor to the doorway of the exit from the corridor or building, whichever is shorter. Exit travel is the distance from the door to the corridor to the point where the building is exited or a stairwell is entered, whichever is shorter. Where the distance to the stairwell is the shorter distance, that distance shall be based on the distance to the door enclosing the stairwell if the stairwell is enclosed, or to the top tread if the stairwell is open.

5.4.12 Vertical Openings.

5.4.12.1 General. These values apply to vertical openings and penetrations, including exit stairways, ramps, and any other vertical exits, pipe shafts, ventilation shafts, duct penetrations, and laundry and incinerator chutes. The charge for vertical openings shall be based on the presence or lack of enclosure and the fire resistance rating of the enclosure, if provided.

5.4.12.2 Open or Incomplete. A vertical opening or penetration shall be classified as an open or incomplete enclosure if it has any of the following characteristics:

(1) It is unenclosed.
(2) It is enclosed but does not have doors.
(3) It is enclosed but has openings other than doorways.
(4) It is enclosed with cloth, paper, or similar materials without any sustained firestopping capabilities.

5.4.12.2.1 If a shaft other than a credited exit route (i.e., credited as one of the multiple routes required in 5.4.10 or in determining travel distance in 5.4.11) is enclosed on all stories but one, and this results in an unprotected opening between that shaft and one, and only one, story, the parameter value assigned to that shaft shall be 0. If a required egress route is contained in that shaft, the parameter value shall be −2.

5.4.12.2.2 If vertical firestopping is incomplete, the vertical opening shall be evaluated using the criteria of 5.4.12.2 and 5.4.12.2.1.

5.4.12.3 Communicating Stories. Communicating stories shall be permitted without enclosure protection between levels, provided they meet the requirements of 22.3.1 or 23.3.1 (NFPA *101*), as appropriate.

5.4.12.4 Open Tiered Cells. The *open or incomplete enclosures* category does not apply to open, multitiered cell blocks in existing buildings classified as single-story buildings in accordance with 5.4.1.

5.4.12.5 Smoke Resistant. A complete enclosure is provided and is capable of resisting the passage of smoke but does not meet the fire resistance requirements of 8.6.5 (NFPA *101*). Unprotected vertical openings in accordance with 22.3.1(2) and 23.3.1.1(2) (NFPA *101*) shall be considered to be smoke resistant.

5.4.12.6 Fire Resistant. A smoke-resistant enclosure is provided that also meets the fire resistance requirements of 8.6.5 (NFPA *101*). Atriums in accordance with 8.6.7 (NFPA *101*) shall be considered to be fire resistant.

5.4.13 Smoke Control. Smoke control definitions are provided in 5.4.13.1 through 5.4.13.4.

5.4.13.1 No Control. Smoke barriers (or horizontal exits) are nonexistent on the story or are not accessible to those confined.

5.4.13.2 Smoke Compartment — Passive. Credit for smoke barriers is given to any facility meeting the requirements of 22.3.7 or 23.3.7 (NFPA *101*), as appropriate.

5.4.13.3 Smoke Compartment — Mechanically Assisted. Mechanically assisted smoke control on a compartment basis must include a smoke barrier (or a horizontal exit) supported by a mechanism of automatic control fans, smoke vent shafts, or a combination thereof to provide a pressure differential that assists in confining smoke to the compartment of origin. Fans involved shall be permitted to be special smoke control fans or special adjustments of the normal building air movement fans.

5.4.13.4 Heat and Smoke Vent System. A heat and smoke vent system is a tested and accepted system that handles smoke in order to maintain the level of smoke above head height in the residential housing area. Methods of judging the acceptability of the system are contained in NFPA 92 and NFPA *101*, A. 23.3.1.3. Additional credit for this system shall be given if the operation of the exhaust system is initiated automatically by smoke detection available in the zone.

5.5 Worksheets for Evaluating Fire Safety. The worksheets for evaluating fire safety zones use an eight-step process found in Figure 5.5.

5.5.1 Step 1 — Complete the Cover Sheet Using Worksheet 5.5.1. See Figure 5.5.

5.5.2 Step 2 — Determine the Most Restrictive Use Condition in the Facility Using Worksheet 5.5.2. See Figure 5.5.

5.5.3 Step 3 — Determine Safety Parameter Values Using Worksheet 5.5.3. Select and circle the safety value for each safety parameter that best describes the conditions in the zone. Choose only one value for each of the 13 safety parameters. If two or more values appear to apply, choose the one with the lowest point value.

5.5.4 Step 4 — Compute Individual Safety Evaluations Using Worksheet 5.5.4. The following steps should be taken:

(1) Transfer each of the 13 circled safety parameter values from Worksheet 5.5.3 to every available block in the line with the corresponding parameter title in Worksheet 5.5.4. Where the block is marked "÷ 2 =," enter one-half the value from Worksheet 5.5.3.
(2) Add each of the four columns, keeping in mind that any negative numbers need to be deducted.
(3) Transfer the resulting values for S_1, S_2, S_3, and S_4 to the corresponding blocks in Worksheet 5.5.6.

5.5.5 Step 5 — Determine Mandatory Safety Requirements Using Worksheet 5.5.5A, 5.5.5B, or 5.5.5C as Appropriate. The following steps should be taken:

(1) Select the proper row in Worksheet 5.5.5A, Worksheet 5.5.5B, or Worksheet 5.5.5C. For high-rise buildings, use Worksheet 5.5.5B. Circle the appropriate values.
(2) Transfer the circled values from Worksheet 5.5.5A, Worksheet 5.5.5B, or Worksheet 5.5.5C to the blocks marked S_a, S_b, S_c, and S_d in Worksheet 5.5.6.

5.5.6 Step 6 — Compute the Fire Safety Equivalency Evaluation Using Worksheet 5.5.6. The following steps should be taken:

(1) Perform the subtractions indicated in Worksheet 5.5.6. Enter the differences in the appropriate answer blocks.
(2) For each row, check "yes" if the value in the answer block is zero (0) or greater. Check "no" if the value in the answer block is a negative number.

5.5.7 Step 7 — Evaluate Other Considerations Not Previously Addressed Using Worksheet 5.5.7. The equivalency covered by Worksheets 5.5.3 through 5.5.6 includes the majority of the considerations covered by the *Life Safety Code*. Some considerations are not evaluated by this method and must be considered separately. These additional considerations are covered in Worksheet 5.5.7, the Facility Fire Safety Requirements Worksheet. Complete one copy of this separate worksheet for each facility.

5.5.8 Step 8 — Determine Equivalency Conclusion. Conclude whether the level of life safety is at least equivalent to that prescribed by the *Life Safety Code* using Worksheet 5.5.8, Conclusions. Worksheet 5.5.8 combines the zone fire safety equivalency evaluation of Worksheet 5.5.6 and the additional considerations of Worksheet 5.5.7.

Chapter 6 Evacuation Capability Determination for Board and Care Occupancies

6.1 General.

6.1.1 This chapter is part of an NFPA guide and, therefore, is not mandatory. The term *shall* in this chapter is used to indicate that if the provisions of the chapter are applied, the procedures mandated are to be followed to ensure the effectiveness of the system. For ease of reading, only the masculine pronoun is used; however, the contents of this chapter apply equally to females and males.

6.1.2 Chapter 33 (NFPA *101*) specifies three sets of requirements for an existing facility based on its evacuation capability. The three levels of evacuation capability defined are *prompt*, *slow*, and *impractical*.

6.1.3 The evacuation capability shall be determined for the residents of a given facility who are living as a group and are provided with staff assistance prior to application of the fire protection requirements. This chapter describes one method for determining evacuation capability.

6.1.4 The evacuation capability for specific facilities, with residents living as a group with staff assistance, is determined by a mathematical method that includes the following:

(1) Determining the evacuation assistance scores of the individual residents
(2) Computing a relative level of evacuation difficulty faced by the resident of a specific facility based on the response capabilities of the staff
(3) Adjusting for vertical egress travel
(4) Calculating an evacuation capability score

6.1.5 Chapter 33 (NFPA *101*) defines the three evacuation capability levels in terms of residents' performance in a timely response to an emergency evacuation with assistance from staff members or other residents. Utilization of this chapter provides a numerical score that can be translated into one of the three levels of evacuation capability.

6.1.6 The evacuation capability shall be permitted to be used with either Chapter 7 of this guide or Chapter 33 (NFPA *101*).

6.2 Procedure for Determining Evacuation Capability.

6.2.1 Methodology. Evacuation capability shall be determined via the worksheets included in Figure 6.8.

6.2.2 Evacuation Capability by Zones.

6.2.2.1 Small facilities (those with no more than 16 residents) shall have their evacuation capability scores based on all the residents and the available staff measured in accordance with the criteria for evaluating residents and staff in this chapter.

6.2.2.2 Large facilities (those with more than 16 residents) shall be permitted to have their evacuation capability score calculated on the basis of the entire building, as with small facilities, or on the basis of separate fire or smoke zones. The

WORKSHEET 5.5.1 COVER SHEET

Fire Safety Evaluation Worksheet for Detention and Correctional Occupancies

Building Identification ______________________________

Evaluator ______________________________ Date ______________________________

Complete one worksheet for each building evaluated.

WORKSHEET 5.5.2 USE CONDITION

_______ Use Condition II — Zoned Egress

_______ Use Condition III — Zoned Impeded Egress

_______ Use Condition IV — Impeded Egress

_______ Use Condition V — Contained

NOTE: If Use Condition III or Use Condition IV is involved, staff location, remote release locks, or fire detection, or any combination of these, must be sufficient to ensure the prompt release required by the use condition checked.

WORKSHEET 5.5.3 SAFETY PARAMETER VALUES

Safety Parameters / **Parameter Values**

1. Construction	V(000)	V(111)	IV(2HH)	III(200)	III(211)	II(000)	II(111)	II(222) or I (ANY)
1 story	−2	0	0	−2	0	0	2	2
2 story	−2	0	0	−2	0	−2	2	2
3 story	−8(−2)[a]	−2(0)[a]	−2(0)[a]	−8(−2)[a]	0	−5(−2)[a]	2	2

	−3	−1	0

7. Interior Finish (Other Areas)	Class C	Class B	Class A
	−2	−1	0

8. Cell/Sleeping Room Enclosure	Cells (Rooms) Face on Corridor (Each Cell is a Separate Residential Housing Area)	Intervening Common Space Within Resid. Housing Area		
		Open	Smoke Resistant <1 Hour	≥1-Hour Fire Resistance–Rated
	0	−3(−5)[c] (0)[d]	0(−2)[c]	2(0)[c]

(Worksheet 5.5.3 continues.)

(For use with NFPA 101A-2016/NFPA *101*-2015) (p. 1 of 4)

FIGURE 5.5 Worksheets for Evaluating Fire Safety in Detention and Correctional Occupancies.

Worksheet 5.5.3 ***Continued***

9. Separation of Resid. Housing Areas from Other Areas	Incomplete		Smoke Resistant <1 Hour	≥1-Hour Fire Resistance–Rated
	Parameter 5 Value <10	Parameter 5 Value = 10		
	−6	2	2(4)[h]	4(2)[b]

10. Exit System	<2 Routes	Multiple Routes		Direct Room Exits
		Deficient	No Deficiencies	
	−6	−2	0	3

11. Exit Access	Dead Ends		No Dead Ends >50 ft and Travel Is[i]		
	>100 ft	>50 ft[i]	>200 ft	≤200 ft >150 ft	≤150 ft
	−2(0)[g]	−1(0)[g]	−2(0)[g]	−1(0)[g]	0

12. Vertical Openings	Open or Incomplete Enclosures			Enclosed[e]	
	Thru ≥4 Stories	2–3 Stories	1 Story	Smoke Resistant	Fire Resistant
	−10(0)[f]	−7(0)[f]	−2(0)[f]	0	2

13. Smoke Control	No Control	Smoke Compartments		Heat + Smoke Vent System
		Passive	Mechanically Assisted	
	−2	2	3	8

[a] Use ( ) if Parameter 5 is 10.
[b] Use ( ) if Parameter 1 is based on II(000), III(200), or V(000) construction and Parameter 5 is 0.
[c] Use ( ) for Use Condition V, new construction, where Parameter 5 is 0.
[d] Use ( ):
– For Use Condition II.
– For Use Condition III if intervening space is ≤50 ft.
– For Use Condition IV if Parameter 5 is ≥8 and intervening space is <50 ft.
For existing buildings if either:
– Parameter 13 = 8, or
– Parameter 5 is ≥8 and Parameter 4 is ≥0.
[e] Use 0 in 1-story buildings.
[f] Use ( ) if Parameter 13 is 8.
[g] Use ( ) if Parameter 10 is –6.
[h] Use ( ) for Use Conditions II, III, and IV, new construction, if cells are facing access corridor.
[i] Use 20 ft for Use Condition V.

For SI units, 1 ft = 0.3048 m; 1 ft² = 0.092 m².

WORKSHEET 5.5.7 FACILITY FIRE SAFETY REQUIREMENTS WORKSHEET

		Yes	No
1.	Utilities and building services conform to the requirements of Sections 22.5 and 23.5, except for enclosure of vertical openings, which have been considered in Safety Parameter 12 of Worksheet 5.5.3.		
2.	24-hour staffing is provided as required by 22.7.1 and 23.7.1.		
3.	Combustibility of furnishing, upholstered furniture, mattresses, and decorations is limited in accordance with 22.7.4 and 23.7.4.		
4.	Portable fire extinguishers are provided at least at staff locations.		
5.	Standpipes are provided in all buildings over two stories in height as required by 22.3.5.5, 22.4.3, or 23.3.5.5.		
6.	If Use Condition III or Use Condition IV is involved, the combination of staff location, remote release locks, and fire detection is sufficient to ensure the prompt release required by those use conditions.		

All references are to NFPA *101*, *Life Safety Code.*

WORKSHEET 5.5.8 CONCLUSIONS

1. ☐ All of the checks in Worksheet 5.5.6 are in the "Yes" column and all applicable considerations in Worksheet 5.5.7 are identified as "Met". The level of fire safety is at least equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for detention and correctional occupancies.

2. ☐ All of the checks in Worksheet 5.5.6 are in the "Yes" column and all considerations identified in Worksheet 5.5.7 as "Not Met" have been evaluated and mitigated to the satisfaction of the AHJ. The level of fire safety is at least equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for detention and correctional occupancies.

3. ☐ One or more of the checks in Worksheet 5.5.6 are in the "No" column or any consideration identified in Worksheet 5.5.7 as "Not Met" has NOT been evaluated and mitigated to the satisfaction of the AHJ. The level of fire safety is not shown by this system to be equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for detention and correctional occupancies.

(For use with NFPA 101A-2016/NFPA *101*-2015) (p. 4 of 4)

FIGURE 5.5 ***Continued***

procedure providing the better (i.e., lower) evacuation capability score shall be permitted to be used. A fire or smoke zone is a portion of the building separated from all other portions of the building by one of the following:

(1) Construction having at least 1-hour fire resistance
(2) A smoke barrier conforming to the requirements of Section 8.5 (NFPA *101*), with the smoke barriers constructed with at least a ½-hour fire resistance rating
(3) In buildings protected throughout with an automatic sprinkler system, construction that is sound and smoke-resistant

6.2.3 If a building is zoned, each zone shall be evaluated separately. The evacuation capability score is based on the residents of that zone and the staff available to that zone in accordance with the staff rating criteria in this chapter.

6.2.4 Where using zones, a separate evacuation capability score shall be determined for zones that include common use spaces where the residents of more than one zone congregate for meals, recreation, or other purposes. In such cases, adjust the resident evacuation assistance scores as appropriate to reflect the different needs that residents might have under such conditions.

6.3 Rating Residents.

6.3.1 Worksheets 6.8.1 through 6.8.4 of Figure 6.8 are used for rating individual residents and also for recordkeeping purposes.

6.3.2 This method of determining evacuation capability has been designed to minimize speculation about how a resident might perform in an actual fire emergency by using ratings based on observed performance. Instead of speculating, raters who are not familiar enough with a resident to provide ratings confidently should consult with an individual who has observed the resident on a daily basis.

6.3.3 Due to the stress of an actual fire emergency, it is likely that some residents will not perform at full capacity. Therefore, ratings based on commonly observed examples of poor performance provide the best readily available indication of behavior that could be reduced by the unusually stressful conditions of an actual fire. All persons are less capable on some occasions, and the ratings should be based on examples of resident performance on a typical "bad" day. Ratings should not be based on rare instances of poor performance.

6.4 Rating Residents Using Worksheets 6.8.1 through 6.8.4.

6.4.1 Risk of Resistance (Line I of Worksheet 6.8.2).

6.4.1.1 General.

6.4.1.1.1 Line I rates the risk that the resident might resist leaving the facility during an emergency evacuation. Unless there is specific evidence that resistance might occur, the resident should be rated as "minimal risk." If more than one rating applies, use the rating with the highest numerical score.

6.4.1.1.2 Specific evidence of resistance means that staff have had to use some physical force in the past. However, an episode of resistance should not be counted if it was the result of a situation that was different enough from an actual fire emergency that it probably does not predict behavior in such an emergency. For example, an incident in which a resident refuses to visit with parents probably does not predict behavior in an actual fire emergency and should not be counted as specific evidence. Resistance can be active (the resident might have struck a staff member or attempted to run away) or passive (the resident might have "gone limp" or hidden from staff members). Simply complaining or arguing is not considered resistance.

6.4.1.2 Minimal Risk. This rating indicates that there is no specific evidence to suggest that the resident might resist an evacuation.

6.4.1.3 Risk of Mild Resistance. This rating indicates that there is specific evidence that the resident might resist leaving the facility. Examples of specific evidence are as follows:

(1) The resident has mildly resisted instructions from staff. Further, the resistance was brief or easily overcome by one staff member and occurred in a situation similar enough to a fire emergency to predict that the behavior could recur during an actual fire emergency.
(2) The resident has hidden from the staff in a situation similar enough to a fire emergency to predict that the behavior could recur during an actual fire emergency. However, once found, the resident offered no further resistance.

6.4.1.4 Risk of Strong Resistance. The resident might offer resistance that necessitates the full attention of one or more staff members. Examples of specific evidence of such risk include the following:

(1) The resident has struggled vigorously in a situation similar enough to a fire emergency to predict that the behavior could recur during an actual fire emergency.
(2) The resident has totally refused to cooperate in a situation that is similar enough to a fire emergency to predict that the behavior could recur during an actual fire emergency.
(3) The resident has hidden in a situation that is similar enough to a fire emergency to predict that the behavior could recur during an actual fire emergency. Moreover, once found, the resident continued to offer resistance.

6.4.2 Impaired Mobility (Line II of Worksheet 6.8.2).

6.4.2.1 General.

6.4.2.1.1 Line II rates the physical ability of the resident to leave the facility. This rating should reflect the current physical environment in the building where the resident lives and should be based on the resident's lying awake on his bed. The resident is rated according to how easily he can leave, given the presence of factors such as physical barriers that hinder movement (e.g., stairs), his ability to get out of bed, or the chairs normally used. The resident should be given credit for being able to use devices that aid movement (e.g., wheelchairs, walkers, crutches, and leg braces). However, the rater shall be permitted to give credit for such devices only if the devices are always available for an emergency evacuation.

6.4.2.1.2 The resident should be rated on his ability to use the most accessible route out of the facility. For example, a resident who is "self-starting" when using the back door but who "needs limited assistance" to get out the front door would be rated as "self-starting."

6.4.2.1.3 The resident should be rated for performance while under the influence of any routinely administered medication that slows movement.

6.4.2.1.4 Where the resident needs physical assistance to make a timely evacuation, the rating of assistance needed is based on the degree of strength used by the staff member to assist the resident. Guiding or directing the resident by giving gentle pushes or leading by the hand is not considered physical assistance. If more than one rating applies, use the rating with the highest numerical score.

6.4.2.2 Self-Starting. The resident is physically able to start and complete an evacuation without physical assistance.

6.4.2.3 Slow. The resident prepares to leave and travels to the exit (or an area of refuge) at a speed significantly slower than normal. Specifically, the resident is rated "slow" if not able to prepare to leave and then travel from his sleeping room to the exit (or area of refuge) within 90 seconds.

6.4.2.4 Needs Limited Assistance. The resident might need some initial or brief intermittent assistance but can accomplish most of the evacuation without assistance. An example of specific evidence of such mobility is that the resident is physically able to start and complete an evacuation, except that the resident needs help to accomplish the following:

(1) Get into a wheelchair
(2) Descend stairs
(3) Get out of bed
(4) Open a door

6.4.2.5 Needs Full Assistance or Very Slow. The resident "needs full assistance" or is "very slow" as defined in 6.4.2.5.1 and 6.4.2.5.2.

6.4.2.5.1 Needs Full Assistance. The resident either needs physical assistance from a staff member during most of the evacuation or must be assisted by staff in one of the following ways:

(1) Carried from the facility
(2) Helped into a wheelchair and wheeled out of the facility
(3) Helped into leg braces and to descend the stairs

6.4.2.5.2 Very Slow. The resident is very slow if the time necessary to prepare to leave and then travel from his sleeping room to the exit is so long that the staff usually assists the resident to evacuate. Specifically, the resident is rated very slow if unable to prepare to leave and then travel to the exit (or area of refuge) within 150 seconds.

6.4.3 Impaired Consciousness (Line III of Worksheet 6.8.2).

6.4.3.1 General.

6.4.3.1.1 Line III rates the risk that a resident could experience a partial or total loss of consciousness in a fire emergency. Unless there is specific evidence that loss of consciousness might occur during a fire emergency, the resident should be rated as "no significant risk."

6.4.3.1.2 Specific evidence is an indication that the resident has experienced some temporary impairment of consciousness of short duration (seconds or minutes) six or more times during the three months preceding the rating of the resident. Regardless of frequency, if there is specific evidence that loss of consciousness might be caused by the stress of a fire emergency, the resident should be rated as having impaired consciousness. An episode of partial loss of consciousness should be counted only if the impairment was severe enough to significantly interfere with the resident's ability to leave the facility. Do not count episodes where the loss of consciousness was the result of a temporary medical problem (e.g., a severe infection). If more than one rating applies, use the rating with the highest numerical score.

6.4.3.2 No Significant Risk. The resident is not subject to loss of consciousness, or the resident has had fewer than six episodes of losing consciousness (partial and total) during the three months preceding the rating.

6.4.3.3 Partially Impaired. The resident has had at least six episodes of losing consciousness in the preceding three months, of which the most severe episode was only a partial loss of consciousness; that is, the resident still is able to participate in an evacuation to some degree. Specific evidence that a resident should be rated in this category includes loss of consciousness resulting from mild (partial or petit mal) seizures, dizzy spells, intoxication, or any other partially incapacitating impairment of consciousness.

6.4.3.4 Totally Impaired. The resident has had at least six episodes of losing consciousness in the preceding three months, the most severe episode involving total or severely incapacitating loss of consciousness; that is, the resident needs the full assistance of at least one staff member to get out of the building. Specific evidence that a resident should be rated in this category includes losses of consciousness resulting from severe (generalized or grand mal) seizures, fainting spells, intoxication, or other total or severely incapacitating loss of consciousness.

6.4.4 Need for Extra Help (Line IV of Worksheet 6.8.2).

6.4.4.1 General.

6.4.4.1.1 Line IV rates the possibility that more than one staff member might be needed to evacuate the resident. Specific evidence is a previous need for two or more persons to assist the resident and an indication that the resident could need assistance from two persons in a fire emergency.

6.4.4.1.2 Where determining the need for additional assistance, the evaluator should disregard the physical strength or weakness of staff members. (For example, a large staff member who is exceptionally strong might be able to assist a resident alone, while a smaller staff member might be unable to assist the resident fully. However, there is no assurance that a staff member who is able to assist alone always will be able to respond to a resident requiring extra assistance.)

6.4.4.2 Needs at Most One Staff Member. There is no specific evidence that the resident might need help from two or more persons in a fire emergency.

6.4.4.3 Needs Limited Assistance from Two Staff Members. The resident might need some initial or brief intermittent assistance from two staff members, but otherwise needs help from no more than one. Specific evidence supporting this rating is that a resident needs assistance from no more than one person except to accomplish the following:

(1) Getting into a wheelchair
(2) Descending stairs

6.4.4.4 Needs Full Assistance from Two Staff Members. The resident might need assistance from two staff members during most of an evacuation. Specific evidence of the need for assistance from two staff members follows:

(1) Two persons are needed to carry the resident from the facility.

(2) Two persons are needed to get the resident into a wheelchair and to get the wheelchair down a flight of stairs.
(3) The resident might resist an evacuation vigorously, and two persons are needed to get the resident out of the facility.

6.4.5 Response to Instructions (Line V of Worksheet 6.8.2).

6.4.5.1 General. Line V rates the resident's ability to receive, comprehend, and follow through with simple instructions during a staff-directed evacuation. Residents often do not respond equally well to all staff members; therefore, a resident should be rated on his responses to staff members whose directions he is least likely to follow. If more than one rating applies, use the rating with the highest numerical score.

6.4.5.2 Follows Instructions. The resident usually can be depended on to receive, comprehend, remember, and follow simple instructions.

6.4.5.3 Requires Supervision. The resident generally is capable of following instruction but is not dependable. Therefore, the resident might need to be guided, reminded, reassured, or otherwise accompanied during evacuation but does not require the exclusive attention of a staff member (e.g., a staff member can lead two or more residents who fit this classification simultaneously).

6.4.5.3.1 This category includes elderly persons who sometimes show early signs of senile dementia or Alzheimer's disease (e.g., confusion, disorientation, frequent "misplacement" of possessions) and young children who cannot be depended on to follow through with instructions.

6.4.5.3.2 Residents in this category generally are capable of following instructions except in one of the following situations:

(1) The resident is deaf or hearing impaired and sometimes misinterprets communications from staff using sign language.
(2) The resident sometimes forgets instructions after a brief period of time.
(3) The resident is sometimes distracted or confused and fails to follow through with instructions.
(4) The resident is sometimes groggy and might fail to listen carefully or follow through with instructions.
(5) The resident is sometimes uncooperative without apparent good reason.
(6) The resident is elderly and sometimes becomes "lost" in a familiar place.
(7) The resident is a young child who might become frightened and not follow through with instructions.

6.4.5.4 Requires Considerable Attention or Might Not Respond.

6.4.5.4.1 The resident might fail to receive, understand, or follow through with instructions; that is, the resident might not respond to instructions or general guidance. Therefore, the resident might require most of the attention of a staff member during an evacuation.

6.4.5.4.2 This category includes elderly persons who have the symptoms of senile dementia or Alzheimer's disease (e.g., severe confusion, disorientation, very limited short-term memory).

6.4.5.4.3 Residents in this category might display one or more of the following characteristics:

(1) The resident sometimes does not understand simple instructions.
(2) The resident might not respond to instructions from a particular staff member.
(3) The resident is sometimes emotionally upset and is therefore unwilling to follow instructions.
(4) The resident is deaf or hearing impaired and the staff cannot communicate reliably with the resident.
(5) The resident is very forgetful, easily confused, or easily distracted.

6.4.6 Waking Response to Alarm (Line VI of Worksheet 6.8.2).

6.4.6.1 General.

6.4.6.1.1 Line VI rates the risk that the fire alarm might fail to awaken the resident.

6.4.6.1.2 Residents should be rated as "response probable" unless any of the following conditions exists:

(1) The building does not have an alarm system meeting the requirements of Chapter 33 (NFPA *101*), or the alarm is not sufficiently loud where the resident sleeps (doors should be closed and barriers kept in place where determining the audibility of the fire alarm).
(2) Medication taken by the resident before retiring differs in type or amount (i.e., medication is increased) from the medication taken during waking hours.
(3) The resident has a readily apparent hearing impairment, or the resident's hearing aid is removed before sleeping.
(4) There is specific evidence that the resident is an exceptionally sound sleeper. For example, the resident previously failed to be awakened by a particularly loud noise, and staff members have had to shake the resident vigorously to awaken him.

6.4.6.1.3 Where any of the conditions in 6.4.6.1.2 exist, the resident should be rated as "response not probable" unless the resident's ability to wake up has been demonstrated. The demonstration of the resident's ability to wake up in response to the fire alarm should be conducted after the first half hour of sleep and during the first three hours of sleep. In addition, the resident's ability to wake up in response to the alarm should be demonstrated on two different nights under normal conditions (e.g., without hearing aid, under usual medications). Also, the resident should be alert enough to follow simple instructions within 1 minute after waking. To avoid waking other residents during the demonstrations of the capability of a particular resident, a device that makes a sound that is similar to, but not louder than, the fire alarm shall be permitted to be used (e.g., an alarm clock or clock radio with a sound similar to the fire alarm). Listed and approved tactile alarms shall be permitted as alternative devices used to demonstrate a hearing-impaired resident's response probability.

6.4.6.2 Response Probable. Either none of the conditions in 6.4.6.1.2 affect the resident, or, if any of the conditions exist, the resident's ability to be awakened has been demonstrated.

6.4.6.3 Response Not Probable. One or more of the conditions in 6.4.6.1.2 affect the resident, and either the resident has not been tested for the ability to be awakened by the fire alarm or the resident has failed to demonstrate the ability to be awakened by the fire alarm.

6.4.7 Response to Fire Drills (Line VII of Worksheet 6.8.2).

6.4.7.1 General.

6.4.7.1.1 Line VII rates the resident's ability to leave the facility during fire drills, as demonstrated by the resident's performance, without guidance or advice from the staff. A resident must demonstrate three separate responses reliably and without instructions or supervision to be rated "yes" in each case. The resident is rated "yes" only where he has been specifically trained or instructed in the desired reaction and has demonstrated the desired response in at least three of the last four fire drills in which a response was demonstrated. If the resident has not been involved in four fire drills, the rating shall be permitted to be "yes" only if the resident has demonstrated the desired response during the last two opportunities to demonstrate the response. Ratings are based on demonstrated performance, and any resident who has not been trained to participate in fire drills must be rated "no."

6.4.7.1.2 This rating covers the ability of the resident to make decisions but does not relate to mobility, which is covered separately. For example, a resident might need assistance only in transferring from a bed to a wheelchair but otherwise can initiate and complete an evacuation promptly. Such a resident would be rated "yes" for "Initiates and Completes Evacuation Promptly" but would be rated "Needs Limited Assistance," in Line II, Impaired Mobility.

6.4.7.1.3 Residents should be rated assuming that an emergency could occur when they are least likely to respond well. For most residents, this is after being awakened. Determining the rating should not include difficulties in actually awakening the resident, since there are great differences in how easily the same individual awakens at various times.

6.4.7.2 Initiates and Completes Evacuation Promptly. The resident has demonstrated a proper response to an alarm or warning of a fire by starting and completing the evacuation without unnecessary delay. Specific evidence leading to a rating of "no" includes the following responses:

(1) The resident might not react to the alarm until alerted by a staff member.
(2) The resident spends an excessive amount of time preparing to leave (e.g., getting dressed, observing others).
(3) The resident has a hearing impairment and, therefore, needs to be alerted by a staff member.
(4) The resident is sometimes upset or confused and, therefore, might seek out a staff member before evacuating.
(5) The resident consistently begins an evacuation but is easily distracted and needs some supervision.

6.4.7.3 Chooses and Completes Backup Strategy. The resident has demonstrated the ability to select an alternative means of escape or has taken other appropriate action if the primary escape route is blocked. Specific evidence leading to a rating of "no" is where the resident is unlikely to select a good course of action if the primary escape route cannot be used; that is, the resident has not been trained to find alternative escape routes, find an area of refuge, or perform other appropriate action(s). Where the resident lacks the conceptual ability to understand fire hazards and blocked escape routes, and, therefore, requires supervision, the rating should be "no."

6.4.7.4 Remains at Designated Location. The resident must have demonstrated willingness to remain at a designated safe location during fire drills. (The whereabouts of already evacuated residents needs to be confirmed to avoid dangerous return trips to look for residents who might have returned to buildings.)

6.4.7.4.1 Specific evidence leading to a "yes" for this rating includes the following:

(1) The resident has been specifically trained to remain at a designated location in a safe area and has demonstrated this ability without the presence of staff members in three of the previous four fire drills.
(2) The resident is physically immobile and, therefore, cannot leave the designated location.
(3) The facility uses a motor vehicle (e.g., a van or bus) or a building that is detached and remote from the facility (i.e., another building or a remote garage) as the designated location, and the resident has demonstrated in three of the previous four fire drills the ability to remain there without the presence of a staff member.
(4) The resident might tend to wander, but a reliable resident has been assigned to keep the wandering resident at the designated location without using any force or coercion. Furthermore, this arrangement has been demonstrated as effective in at least three of the previous four fire drills.

6.4.7.4.2 Specific evidence leading to a "no" for this rating includes the following:

(1) The resident has not been trained to remain at a designated location without any staff supervision.
(2) The resident has been trained to remain without staff supervision at a designated location but has failed to demonstrate this capability in three of the previous four fire drills.

6.5 Rating the Staff Shift (Worksheets 6.8.5 through 6.8.11).

6.5.1 This rating is intended to predict the promptness of response of a staff member who is present in the facility, at a given time (shift), and who is capable of assisting residents in an evacuation.

6.5.2 Before rating the staff shift, there are five basic requirements relative to the staff response capability, protection plans, and fire drills that shall be met. The determination of whether or not these requirements are met is recorded on Worksheet 6.8.8, Staff Shift Scores. If the corresponding requirements of 6.5.2.1 through 6.5.2.5 have been met, a "yes" rating should be given.

6.5.2.1 A protection plan shall have been promulgated, and all staff members considered in this rating shall have been trained in its implementation. Regardless of the staff's everyday competencies, they cannot be relied upon to innovate effective life safety actions under the extreme stress and time limitation of an actual fire emergency. Notwithstanding the facility's fire protection features, the staff must have a valid and practiced plan of action that can be put into effect immediately in an emergency. The protection plan should include the following features:

(1) A description of all available evacuation, escape, and rescue routes and the procedures and techniques needed to evacuate all the residents using the various routes
(2) A fundamental knowledge of fire growth, containment, and extinguishment necessary to make reasonable judgments about action priorities and viable egress routes

6.5.2.2 Staff shall be provided in accordance with 6.5.2.2.1 or 6.5.2.2.2.

6.5.2.2.1 The total available staff at any given time is able to handle the individual evacuation needs of each resident who might be in the facility. In calculating evacuation capability, it might be possible to have a ratio of staff to residents that appears to be favorable but that still is unacceptable under this system. This would be the case when a resident needs assistance from two staff members but only one staff member is present. Thus, the situation should be such that all residents can be evacuated by the available staff.

6.5.2.2.2 The facility meets the criteria for an evacuation capability level of "impractical," the resident whose evacuation needs cannot be handled is in a sleeping room or other room that provides adequate refuge from fire outside the room, and there is at least one staff member present who can close the door to the room. For example, a very heavy resident is in a facility, meeting the criteria for impractical level of evacuation capability, with one available staff member who cannot transfer the resident from a bed to a wheelchair. Although the staff member is unable to meet all the resident's evacuation assistance needs, the sleeping room provides adequate refuge.

6.5.2.3 Every staff member considered in this rating shall be able to participate meaningfully in the evacuation of every resident. For example, a staff member who, due to his own disability, might be unable to assist one or more physically disabled residents shall not be included in the rating. However, if a staff member's disability does not limit his ability to assist the residents, then the staff member shall be permitted to be included in the rating.

6.5.2.4 All staff members considered in this rating shall be in the facility when on duty, except as otherwise permitted by 6.5.2.4.1 through 6.5.2.4.4. This rating is based on the assumption that there are staff present when residents are in the facility.

6.5.2.4.1 Unstaffed facilities, which are not covered by this system, shall be permitted to be assigned an evacuation capability level based on the demonstrated ability of the residents to meet the criteria of Chapter 33 (NFPA *101*) without staff assistance.

6.5.2.4.2 Residents who receive only the most favorable ratings on Worksheet 6.8.3 for rating residents shall be permitted to be present in the facility without the presence of staff members.

6.5.2.4.3 A staff member shall be permitted to be at a location outside of the facility where his ability to respond to a fire emergency from the location is roughly equivalent to his response ability from within the facility. In determining equivalency, the authority having jurisdiction should consider the following:

(1) Whether the fire alarm meets the minimum loudness criteria *(see 6.5.3.2.2)* at the locations outside the facility or whether another staff member who is required to remain in the facility can immediately report a fire emergency to the staff member who is outside
(2) Travel time to the facility
(3) Detection of fire cues (e.g., smoke, noises) from locations outside the facility
(4) Whether the staff member will be notified immediately about which area of the facility has the fire emergency, if the staff member who is outside is required to report fire emergencies in more than one facility or fire zone

6.5.2.4.4 The authority having jurisdiction shall be permitted to grant partial credit (which shall not exceed the promptness of the response score that the staff member receives where required to remain in the facility) for staff members who are permitted at locations outside the facility and who have the ability to respond promptly.

6.5.2.5 Fire drills shall be conducted monthly, and at least 12 fire drills shall have been conducted during the previous year. A facility in operation for less than one year shall be permitted to have conducted a fire drill for each month of its operation.

6.5.3 Staff Shift Scores (Worksheet 6.8.8).

6.5.3.1 The purpose of this rating is to determine which staff shift is likely to be the least able to respond promptly to assist residents in an evacuation. If it is not obvious which staff shift will be the least able to respond, complete separate forms for each staff shift and use the staff shift having the lowest score.

6.5.3.2 Promptness of Response Scores (Worksheet 6.8.7).

6.5.3.2.1 Staff Availability. This rating determines whether there are circumstances in which a staff member is less able to respond appropriately or might be delayed in his response to a fire emergency. A staff member shall be included in this rating only under the following conditions:

(1) He is required to remain within the facility while on duty.
(2) He sleeps less than 100 ft (30 m) from all locations in the portion of the facility being evaluated.
(3) His travel time to any location in the portion of the facility being evaluated does not exceed 60 seconds.

6.5.3.2.1.1 Standby or Asleep. This rating means that the staff member does not have specific duties that ensure an immediate response to the alarm but is otherwise available to assist in a timely manner. This includes live-in staff who might be asleep, showering, or otherwise unable to respond immediately.

6.5.3.2.1.2 Immediately Available. This rating means that the staff member is required to be on duty to provide immediate assistance but is not required to remain in proximity to the residents (e.g., the staff member is allowed to wash clothes or do bookkeeping).

6.5.3.2.1.3 Immediately Available and Close By. This rating means that the staff member, in addition to satisfying the requirement for "immediately available," also is required to remain in proximity to the residents except for brief periods of time.

6.5.3.2.1.4 If the facility is classed as "large" and has multiple fire or smoke zones, some staff members might have responsibilities for residents outside the fire or smoke zone being evaluated. If a staff member's duties include rescue of residents in the fire zone being evaluated, the staff member shall be permitted to be assigned partial or full promptness of response scores. The authority having jurisdiction shall assign the points based on the proximity of the staff member to the zones and the nature of his duties in a fire emergency. This credit shall be given only if there is a smoke detection system that alerts the staff member and a system or procedure for promptly informing the staff member of the general location of the fire.

6.5.3.2.1.5 Individual residents shall be permitted to be assigned responsibilities similar to those of staff members to assist other residents during fire emergencies. The authority having jurisdiction shall be permitted to assign these individual residents as many as eight points for promptness of response, based on their capabilities and responsibilities.

6.5.3.2.2 Alarm Effectiveness. This rating determines whether smoke detector–activated alarm devices are loud enough to alert the staff to a fire emergency dependably.

6.5.3.2.2.1 Assured. To be rated "assured," the alarm shall be "easily noticeable" in all locations where the staff member is permitted, regardless of his rating on the promptness of response factor. "Easily noticeable" means the alarm shall be a minimum of 55 dBA measured at ear level. The authority having jurisdiction shall be permitted to require the alarm to be louder than 55 dBA where background noises could interfere with alarm audibility. For example, the alarm might need to be more than 55 dBA to be heard over noise such as from a washing machine in the laundry or a television in the day room. If there are staff who are permitted to sleep, the alarm shall be a minimum of 70 dBA measured at "pillow" level in any area where the staff might be asleep. The alarm shall be activated by smoke detectors, an automatic sprinkler system, or both. If the facility has smoke detectors meeting the requirements of Chapter 33 (NFPA *101*), the smoke detectors shall activate the alarm. If the facility has an automatic sprinkler system whose fire protection properties are considered in the evaluation of the facility, activation of the sprinkler system shall activate the alarm.

6.5.3.2.2.2 Not Assured. The alarm does not satisfy the conditions specified under "assured." Doors that normally are closed during the staff shift being rated should be closed when determining the loudness of the fire alarm. Any other barriers that could reduce the loudness of the fire alarm also shall be in place.

6.6 Rating the Facility (Worksheet 6.8.9).

6.6.1 The vertical distance from sleeping rooms to a story with exits might affect the risk because of the time and difficulty in moving on the stairs.

6.6.2 Special Terminology.

6.6.2.1 Direct Exit. Direct exit shall mean that there is no more than one step between the inside of the facility and either (1) ground level outside or (2) a level area outside the facility that is at least 32 ft^2 (3 m^2). This level area might be a porch or a stairway landing. Where the vertical distance is greater than one step, a ramp shall be permitted to be used to comply with this definition.

6.6.2.2 Vertical Distance. Vertical distance shall refer to the greatest number of stories that separate any resident sleeping room from its nearest direct exit.

6.6.3 All Sleeping Rooms on Stories with Direct Exit. Every room where residents sleep is on a story with at least one direct exit. Examples of facilities that fall within this category include the following:

(1) A one-story building without sleeping rooms in the basement
(2) A two-story building without sleeping rooms on the second story
(3) A split-level building with direct exits at each level
(4) A two-story building with sleeping rooms on the second story that has an exterior stairway from the second story, with a landing at the second story that is greater than 32 ft^2 (3 m^2)

6.6.4 Any Sleeping Room One Story from Exit. There is at least one room where residents sleep in which the shortest vertical distance to a direct exit is one story. Examples of facilities that fall within this category include the following:

(1) A two-story building with sleeping rooms on the second story, in the basement, or both
(2) A one-story building where all the exits have stairs that lead to grade without a landing or porch of, at minimum, 32 ft^2 (3 m^2)

6.6.5 Any Sleeping Room Two or More Stories from Exit. There is at least one room where residents sleep in which the shortest vertical distance to a direct exit is two or more stories. Buildings that fall within this category include the following:

(1) A three-story building with sleeping rooms on the third story and no exterior fire escape
(2) A three-story building with sleeping rooms on the third story that has an exterior stairway from the third story, but where the landing at the third story is less than 32 ft^2 (3 m^2)

6.6.6 Facilities in an Apartment House. If the facility is located in an apartment house and the unit containing the facility requires ascending or descending stairs to move from any sleeping room to the door to the corridor, a score of 1.2 for "vertical distance from sleeping rooms to exit" should be assigned. In all other apartments, the score for vertical distance from sleeping rooms to exits is 1.0.

6.7 Determining Evacuation Capability (Worksheet 6.8.10).

6.7.1 When the scores for the residents, the staff, and the vertical travel distances have been determined, the scores are entered on Worksheet 6.8.10 and the calculation made to obtain a numerical result.

6.7.2 The numerical evacuation capability score then is translated into a level of evacuation capability of either "prompt," "slow," or "impractical" and recorded on Worksheet 6.8.11. This evacuation capability is a valid assessment that shall be permitted to be used in Chapter 7 of this guide or in Chapter 33 (NFPA *101*).

6.8 Worksheets for Rating Residents. The worksheets for rating residents use a seven-step process found in Figure 6.8.

6.8.1 Step 1 — Complete the Cover Sheet Using Worksheet 6.8.1. See Figure 6.8.

6.8.2 Step 2 — Read Section 6.3 and Section 6.4, then Fill out Worksheets 6.8.2 and 6.8.3. Complete both forms for each resident, basing the ratings on commonly observed examples of poor performance.

6.8.3 Step 3 — Compute the Total Resident Evacuation Assistance Score. The following steps should be taken:

(1) List each resident's name on Worksheet 6.8.4. Use a separate scoresheet for each zone being rated. Use additional scoresheets for a large number of residents.
(2) Enter the score for each resident from Worksheet 6.8.3 that was completed for him.
(3) Total the scores for all residents in the facility or zone being rated, as appropriate.

WORKSHEET 6.8.1 COVER SHEET

Worksheet for Rating Residents

Resident's name ______________________ Evaluator ______________________

Facility ______________ Zone ______________ Date ______________

Write any explanatory remarks here:

WORKSHEET 6.8.2 RATING THE RESIDENT ON THE RISK FACTORS

Rate the resident on each of the factors below by checking the one circle for each risk factor that best describes the resident. For the first six factors, write the scores for the circles checked in the appropriate score boxes in the far right column. For "Response to Fire Drills," write the three checked scores in the large circles. Write the sum of the three scores in the large box on the right.

					Score Boxes
I. Risk of Resistance (Check only one)	Minimal Risk ○ score=0	Risk of Mild Resistance ○ score=6	Risk of Strong Resistance ○ score=20		☐
II. Impaired Mobility (Check only one)	Self-Starting ○ score=0	Slow ○ score=3	Needs Limited Assistance ○ score=6	Needs Full Assistance or Very Slow ○ score=20	☐
III. Impaired Consciousness (Check only one)	No Significant Risk ○ score=0	Partially Impaired ○ score=6	Totally Impaired ○ score=20		☐
IV. Need for Extra Help (Check only one)	Needs at Most One Staff ○ score=0	Needs Limited Assistance from 2 Staff ○ score=30	Needs Full Assistance from 2 Staff ○ score=40		☐
V. Response to Instructions (Check only one)	Follows Instructions ○ score=1	Requires Supervision ○ score=3	Requires Considerable Attention/Might Not Respond ○ score=10		☐
VI. Waking Response to Alarm (Check only one)	Response Probable ○ score=0	Response Not Probable ○ score=6			☐

VII. Response to Fire Drills (Without guidance or advice from staff)	Initiates and Completes Evacuation Promptly	Yes ○ score=0	No ○ score=8	○
	Chooses and Completes Back-up Strategy	Yes ○ score=0	No ○ score=4	+ ○
	Remains at Designated Location	Yes ○ score=0	No ○ score=6	+ ○

Sum of These Three Scores ☐

WORKSHEET 6.8.3 DETERMINING THE RESIDENT'S OVERALL NEED FOR ASSISTANCE

Compare the numbers in the seven score boxes filled in on Worksheet 6.8.2. Take the highest score from the score boxes and write it in the box at the right.

Evacuation Assistance Score ☐

Notes:

(For use with NFPA 101A-2016/NFPA *101*-2015) (p. 1 of 4)

WORKSHEET 6.8.5 COVER SHEET

Staff Shift Score

Facility ______________________ Zone ______________________

Evaluator ______________________ Date ______________________

Staff Shift: From ______________________ To ______________________

WORKSHEET 6.8.6 STAFF RESPONSE AND TRAINING

	Yes	No
A protection plan has been promulgated and all staff members considered in this rating have been trained in its implementation. *(See 6.5.2.1.)*		
The total available staff at any given time is able to handle the individual evacuation needs of each resident who is in the facility. *(See 6.5.2.2.)*		
Every staff member considered in this rating can meaningfully participate in the evacuation of every resident. *(See 6.5.2.3.)*		
All staff members considered in this rating are required to be in the facility when on duty, except as permitted. *(See 6.5.2.4.)*		
At least 12 fire drills were conducted during the previous year. *(See 6.5.2.5.)*		

All items must score "Yes" before proceeding.

WORKSHEET 6.8.7 PROMPTNESS OF RESPONSE SCORES

	Alarm Effectiveness	
Staff Availability	**Assured**	**Not Assured**
Standby or asleep	16	2
Immediately available	20	2
Immediately available and close by	20	10

WORKSHEET 6.8.9 RATING THE FACILITY

	Vertical Distance from Sleeping Rooms to Exits		
	All SR on Stories with Direct Exit	Any SR One Story from Exit	Any SR Two or More Stories from Exit
Small Facility[a]	◯ Score 0.8	◯ Score 1.0	◯ Score 1.2
Large Facility or Apartment[b]		◯ Score 1.0	

[a] Small facilities have 16 or fewer residents.
[b] See 6.6.6 for apartments.

WORKSHEET 6.8.10 CALCULATION OF EVACUATION CAPABILITY SCORE

$$\frac{\text{Total Resident Evacuation Assistance Score (Worksheet 6.8.4)} \; \boxed{} \times \text{Vertical Distance from Sleeping Room to Exit (Worksheet 6.8.9)} \; \boxed{}}{\boxed{} \; \text{Staff Shift Score (Worksheet 6.8.8)}} = \boxed{} \; \text{Evacuation Capability Score}$$

(go to Worksheet 6.8.11)

WORKSHEET 6.8.11 EVACUATION CAPABILITY SCORE

Evacuation Capability Score	Level of Evacuation Capability	Evacuation Capability for this Facility or Zone
≤1.5	Prompt	
>1.5 to ≤5.0	Slow	
>5.0	Impractical	

(For use with NFPA 101A-2016/NFPA *101*-2015) (p. 4 of 4)

FIGURE 6.8 ***Continued***

6.8.4 Step 4 — Consider Prequalifications Related to Computing. The following steps should be taken:

(1) Complete the cover sheet in Worksheet 6.8.5.
(2) Complete Worksheet 6.8.6 for the time of day, week, and so on when the combined ratings for staff and residents yield the highest score. This usually is late at night. Where it is not obvious which staff shift will score highest, complete separate forms for each staff shift and utilize the highest score. Read Section 6.5 before filling out this form.

6.8.5 Step 5 — Determine the Staff Shift Score. Note that in large facilities, staff members might be responsible for assisting residents in a fire or smoke zone but also might have responsibilities for residents in other zones. *(See Section 6.5.)* The following steps should be taken:

(1) On Worksheet 6.8.8, list the names of staff members who are required to be on duty in the facility during the shift being rated.
(2) Determine whether the effectiveness of the alarm is "assured" or "not assured." *(See 6.5.3.2.2.)*
(3) Using the values from Worksheet 6.8.7, determine each staff member's "promptness of response score" for the shift being rated. Enter each staff member's name and score in the appropriate spaces on Worksheet 6.8.8.
(4) Total the "promptness of response scores" for the shift rated.

6.8.6 Step 6 — Rate the Facility Using Worksheet 6.8.9. Rate the facility by checking the circle that indicates the vertical distance a resident must travel from a sleeping room (SR) to an exit.

6.8.7 Step 7 — Determine Evacuation Capability. Determine the facility's evacuation capability, using Worksheet 6.8.10. Calculate the score by multiplying the Total Resident Evacuation Assistance Score (Worksheet 6.8.4) by the Vertical Distance from Sleeping Room to Exit (Worksheet 6.8.9) and then dividing by the Staff Shift Score (Worksheet 6.8.8). The evacuation capability is determined and recorded in Worksheet 6.8.11.

Chapter 7 Fire Safety Evaluation System for Board and Care Occupancies

7.1 Introduction.

7.1.1 This chapter is part of an NFPA guide and, therefore, is not mandatory. The term *shall* in this chapter is used to indicate that if the provisions of the chapter are applied, the procedures mandated are to be followed to ensure the effectiveness of the evaluation system.

7.1.2 Chapter 33 (NFPA *101*) defines three levels of evacuation capability for residents (with staff assistance): *prompt*, *slow*, and *impractical*. Chapter 33 (NFPA *101*) also prescribes the fire safety protection requirements for each level of evacuation capability. This chapter describes a procedure for determining whether a combination of fire safety features in a board and care facility provides a level of safety equivalent to that provided by explicit conformance to Chapters 32 and 33 (NFPA *101*). The definition of evacuation capability is given in Section 3.3 (NFPA *101*), and one procedure for determining evacuation capability is presented in Chapter 6 of this document.

7.1.3 Subsystems are provided as follows:

(1) Section 7.2 — Evaluating the fire safety protection in a small facility
(2) Section 7.4 — Evaluating the fire safety protection in a large facility
(3) Section 7.6 — Evaluating the suitability of an apartment building to house a board and care occupancy

7.2 Glossary for Fire Safety Evaluation Worksheet for a Small Facility.

7.2.1 Introduction. This glossary is provided to assist in completing Figure 7.3, Worksheets for Evaluating Fire Safety for a Small Facility, to determine the suitability of a small facility to house a board and care occupancy. The instructions for the mechanisms of completing the worksheet are included in Section 7.3. They are not repeated in this glossary. This glossary provides expanded discussion and definitions for the various items in the worksheet to assist the user where questions of definition or interpretation arise. To the maximum extent possible, the glossary does not repeat the definitions already existing in NFPA *101* but rather references the appropriate paragraphs in NFPA *101*.

7.2.2 Areas of Application.

7.2.2.1 The evaluation shall be completed covering the entire home, including spaces that are not used by the residents of the board and care home. See Worksheet 7.3.2. Row houses, townhouses, or other forms of independent living units having all of their entrances and means of escape completely separate from any other unit shall be permitted to be calculated as small facilities where they are separated from any abutting living units. Such separation shall be by fire-resistive partitions or walls having at least a 1-hour fire resistance rating and extending to the roof if it is noncombustible, or through the roof if the roof or its covering is of combustible material.

7.2.2.2 For dwelling units (apartments) in general-use apartment houses, the worksheet shall be used to evaluate the dwelling unit being used as the board and care home. The remainder of the apartment building shall be evaluated using the worksheet to determine the suitability of apartment buildings to house a board and care occupancy.

7.2.3 Maintenance. All protection systems, requirements, arrangements, and procedures shall be maintained in a dependable operating condition and a sufficient state of readiness and shall be used in such a manner that the intended safety function or hazard constraint is not impaired. Otherwise, they shall receive no credit in the evaluation.

7.2.4 Safety Parameters (Worksheet 7.3.2). The safety parameters are a measure of those building factors that bear upon or contribute to the safety of those persons who might be in the building at the time of a fire. Each of the safety parameters is to be analyzed, and the safety value for each parameter that best describes the condition in the building is to be identified. Only one value for each of the parameters is to be chosen. If two or more values appear to apply, the one with the lowest point value shall be used.

7.2.4.1 Construction/Fire Resistance. Construction types are as defined in 7.2.4.1.1 and 7.2.4.1.2, except that sprinkler protection shall not be considered in determining construction classification in any case where credit is given for sprinkler protection as defined in 7.2.4.5.

7.2.4.1.1 Protected (15 minutes). Buildings meeting the requirements of 33.2.1.3.2 (NFPA *101*).

7.2.4.1.2 Protected (1 hour). Buildings meeting the requirements of Type I, Type II(222), Type II(111), Type III(211), Type IV, or Type V(111) construction.

7.2.4.2 Hazardous Areas. The assignment of parameter values for hazardous areas is a four-step process.

7.2.4.2.1 Step 1 — Identify Hazardous Areas. Hazardous areas are as defined in 32.2.3.2 and 33.2.3.2 (NFPA *101*).

7.2.4.2.2 Step 2 — Determine the Area Exposed.

7.2.4.2.2.1 Primary Means of Escape. Hazardous area is on the same story as and is in or abuts a primary means of escape, as defined in 32.2.3.2 and 33.2.3.2 (NFPA *101*).

7.2.4.2.2.2 Sleeping Area. Hazardous area is on the same story as and is in or abuts the sleeping area (room).

7.2.4.2.3 Step 3 — Determine the Fire Protection Provided.

7.2.4.2.3.1 Sprinkler Protection. The hazardous area is protected by sprinklers (or other appropriate automatic extinguishing system).

7.2.4.2.3.2 Smoke-Resisting Separation. The hazardous area is separated from exposed sleeping areas and the primary means of escape routes by a separation that resists the passage of smoke. Any doors in such separation are self-closing or automatic-closing upon detection of smoke.

7.2.4.2.3.3 Half-Hour Fire Resistance–Rated Enclosure. Enclosures meeting the requirements of 32.2.3.2.5(1) and 33.2.3.2.5(1) (NFPA *101*).

7.2.4.2.3.4 1-Hour Fire Resistance–Rated Enclosure. Enclosures meeting the requirements of 32.2.3.2.4(1) and 33.2.3.2.4(1) (NFPA *101*).

7.2.4.2.4 Step 4 — Determine Degree of Deficiency and Assign Parameter Values. The parameter value ultimately is determined on the basis of the area exposed and the level of protection provided. Table 7.2.4.2.4 provides a matrix for determining the degree of deficiency to be assessed. In some situations, more than one hazardous area with the same or differing levels of deficiency exists. The parameter value then is based on the single most serious deficiency for the hazardous area.

7.2.4.3 Manual Fire Alarm. Manual fire alarms are defined in 7.2.4.3.1 through 7.2.4.3.3.

7.2.4.3.1 None or Incomplete. There is no manual fire alarm system, or the system is incomplete and does not meet the requirements necessary for a higher-scored category.

7.2.4.3.2 Without Fire Department Notification (W/O F.D. Notification). The credit for this level of protection is to be given for any installation that meets the requirements for a manual fire alarm system in 32.2.3.4.1 and 33.2.3.4.1 (NFPA *101*).

7.2.4.3.3 With Fire Department Notification (W/ F.D. Notification). There is a manual fire alarm system meeting the requirements of Section 9.6 (NFPA *101*), including fire department notification as defined in 9.6.4 (NFPA *101*).

7.2.4.4 Smoke Detection and Alarm. A detection system as used herein is one based on the use of smoke detectors. No recognition is given for thermal detectors. The detection system categories are described in 7.2.4.4.1 through 7.2.4.4.5.

7.2.4.4.1 None or Incomplete. There are no smoke detectors in the building, or, if any are present, they do not meet the requirements for a higher-scored category.

7.2.4.4.2 Single-Level Detection, Limited Warning. There are one or more detectors in the building, but they do not meet the criteria for every level detection set forth in 7.2.4.4.3. Detectors credited in this category shall be permitted to be any approved smoke detector, including a single-station detector. At least one detector must be located in the corridor or similar common space (lobbies, lounges, or other spaces that cannot be closed off) in the immediate vicinity of each separate sleeping area. If there is more than one sleeping area, each such area must be protected to obtain this credit.

7.2.4.4.3 Every Level Detection. This credit applies where the detector system meets the requirements of 32.2.3.4.3 and 33.2.3.4.3 (NFPA *101*).

7.2.4.4.4 Every Level Plus Single-Station Detection in Each Bedroom. To receive this credit, the requirements of 7.2.4.4.3 must be met in full with the addition of at least one single-station detector in each bedroom or other sleeping area.

7.2.4.4.5 Total Coverage System. This system provides a minimum of one detector in each occupied room or other habitable space and throughout any basements, storage areas (other

Table 7.2.4.2.4 Hazardous Areas — Degree of Deficiency

	Nonsprinklered			Sprinklered	
	Fire resistance rating with automatic fire detection				
	½ hour	1 hour	Unenclosed	Smoke-resistive separation	Unenclosed
Does not expose sleeping area or means of escape routes	No deficiency	No deficiency	Single deficiency	No deficiency	No deficiency
Exposes sleeping area or means of escape routes	Single deficiency	No deficiency	Double deficiency	No deficiency	No deficiency

than normal clothing closets), or combustible loft spaces. To qualify as a total system, there must be a manual fire alarm system in the building, and the operation of any smoke detector must automatically activate the manual fire alarm system evacuation alarm for the entire building.

7.2.4.5 Automatic Sprinklers. Automatic sprinklers are defined in 7.2.4.5.1 and 7.2.4.5.2.

7.2.4.5.1 Nonsprinklered. No credit is given if there are no sprinklers or if sprinklers, though present, are not sufficient to qualify for the sprinklered category.

7.2.4.5.2 Sprinklered ("Standard Sprinklers" or "Quick-Response or Residential Sprinklers"). The building is sprinklered in accordance with 32.2.3.5.1 through 32.2.3.5.7 and 33.2.3.5.3 through 33.2.3.5.7 (NFPA *101*).

7.2.4.6 Interior Finish. Except as noted in 7.2.4.6.1, classification of interior finish on the walls and ceilings of the occupied space is in accordance with Section 10.2 (NFPA *101*). There are no requirements for interior floor finish. Choose the safety parameter value in Worksheet 7.3.2 based on the interior finish material provided. For example, if the interior wall finish material has a flame-spread index of between 25 and 75, do not take the parameter value associated with a flame-spread index of less than 25, regardless of the presence of automatic sprinkler protection. The mandatory values have been calibrated to take into consideration any sprinkler protection provided.

7.2.4.6.1 Interior wall and ceiling finish materials tested in accordance with NFPA 265 or NFPA 286 as permitted by Section 10.2 (NFPA *101*), and meeting the criteria established in Section 10.2 (NFPA *101*) for those test standards, shall be scored as Class A interior finish materials (flame spread ≤25).

7.2.4.6.2 No consideration is included in the safety parameter value for any finish with a flame-spread index greater than 200 as measured by ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*. Some materials, including foam plastics, high density polyethylene, and polypropylene, are not permitted to be tested in accordance with ASTM E84 and must be tested in accordance with NFPA 286, and must meet the acceptance criteria shown in 10.2 (NFPA *101*). Some materials, including asphalt-impregnated paper, are capable of inducing extreme rates of fire growth and rapid flashover. In any case involving these materials, the resultant hazard is considered beyond the capacity of this evaluation system and requires an individual fire hazard assessment. The following should be noted:

(1) Plywood of ¼ in. (6 mm) or greater thickness should be considered as having a flame-spread index of ≤200.
(2) Exposed wood open-joist construction or other exposed wood construction areas shall be charged as Class C interior finish, in addition to any charges under 7.2.4.1.
(3) If a space is classified as hazardous under 7.2.4.2, no additional charge shall be made as the result of interior finish in such areas.

7.2.4.7 Separation of Sleeping Rooms (from Other Levels and from Corridors). Separation of sleeping rooms is described in 7.2.4.7.1 through 7.2.4.7.3.

7.2.4.7.1 Separation of Sleeping Rooms from Other Levels. The classification of separation of sleeping rooms is categorized under the groups headed "Unprotected Vertical Openings" and "Protected Vertical Openings" (Parameter 7 in Worksheet 7.3.2). Determine the extent of vertical openings and number of stories connected.

7.2.4.7.1.1 Use the category of "Protected Vertical Openings" if any of the following apply:

(1) A single-story building without a basement
(2) All vertical openings, other than a two-story open stair in a sprinklered building, protected by a ½-hour or greater fire resistance–rated smoke partition
(3) All vertical openings, other than a three-story open stair in a sprinklered building where the primary means of escape from each sleeping area does not require occupants to pass through a story on the lower level, protected by a ½-hour or greater fire resistance–rated smoke partition
(4) All vertical openings protected by a ½-hour or greater fire resistance–rated smoke partition

7.2.4.7.1.2 Where none of the conditions in 7.2.4.7.1.1 apply, use the category of "Unprotected Vertical Openings."

7.2.4.7.2 Separation of Sleeping Rooms from Corridors and Common Spaces. The charge for "None or Incomplete" (Parameter 7 in Worksheet 7.3.2) is assessed in any case where the separation of sleeping rooms from corridors and common spaces is insufficient to meet any of the other classifications in this parameter.

7.2.4.7.3 Criteria for the Other Classifications of Sleeping Room Separation.

7.2.4.7.3.1 Smoke Resisting. Sleeping rooms are separated from corridors or other common spaces in accordance with 32.2.3.6 and 33.2.3.6 (NFPA *101*) without the door closer.

7.2.4.7.3.2 Smoke Resisting with Door Closer. Sleeping rooms are separated in accordance with 32.2.3.6 and 33.2.3.6 (NFPA *101*) with door closer.

7.2.4.7.3.3 Half-Hour Fire Resistance. Meets the requirements of 32.2.3.6 and 33.2.3.6 (NFPA *101*) without the door closer.

7.2.4.7.3.4 Half-Hour Fire Resistance with Door Closer. Sleeping rooms are separated in accordance with 32.2.3.6 and 33.2.3.6 (NFPA *101*) with door closer.

7.2.4.7.3.5 Half-Hour Fire Resistance with Automatic-Closing Doors. Automatic-closing doors shall be permitted if the doors have an arrangement that holds them open in a manner such that they are released by a smoke detector–operated device (e.g., magnetic or pneumatic hold-open device) prior to the passage of significant smoke from the space of fire origin into the corridor or from the corridor into the protected room. Smoke detectors for operation of such doors are either integral with the door closers, mounted at each door, or operated from a total smoke detection system covering both the room and corridor.

7.2.4.8 Means of Escape. Means of escape is defined in 7.2.4.8.1 through 7.2.4.8.6.

7.2.4.8.1 Means of Escape on All Sleeping Levels. A building shall be considered as having means of escape on all sleeping levels, provided the following conditions exist:

(1) The entire building is on a single level.
(2) All guest rooms used for sleeping are on a level having an exit door.

7.2.4.8.2 Primary Route. A normal means of escape that might involve interior or exterior stairs, corridors, doors, or other common means of movement through and out of a dwelling unit.

7.2.4.8.2.1 Protected. A primary route is classed as "protected" if it provides a path of travel to the outside of the building without traversing any corridor or space exposed to an unprotected vertical opening. Also, where the sleeping room is above or below the level of exit discharge, the primary means is an enclosed interior stair in accordance with 32.2.2.4 or 33.2.2.4 (NFPA *101*), an exterior stair, or a horizontal exit.

7.2.4.8.2.2 Unprotected. A primary route is classed as "unprotected" if it does not meet the requirements for "protected."

7.2.4.8.3 Fewer Than Two Remote Routes. The egress capability is classed as "<2 remote routes" if each bedroom does not have access to two routes leading to two separate building exit doorways.

7.2.4.8.4 With Alternative Means. The credit for this level of protection applies to any facility that meets the requirements for a second means of escape in 32.2.2.3 and 33.2.2.3 (NFPA *101*).

7.2.4.8.5 Two Remote Routes. To meet the requirement for "two remote routes," each bedroom must have access to two routes leading to two separate building exit doorways.

7.2.4.8.5.1 Separated. To meet the requirement for "two remote routes separated," the facility must meet the requirements of 32.2.2.2 through 32.2.2.3 and 33.2.2.1 (NFPA *101*).

7.2.4.8.5.2 Unseparated. The two remote routes do not meet the requirements for the classification "separated."

7.2.4.8.6 Direct Exit from Each Bedroom.

7.2.4.8.6.1 To be credited, each bedroom must have a door that is operable by the room occupant(s) and such door opens directly to grade without more than one step, opens directly to a ramp to grade, or opens directly to an external porch or landing with external stairs or other suitable access to grade.

7.2.4.8.6.2 Some buildings have a nonsleeping occupants use area (e.g., staff lounge) on a story without any exit, and the building otherwise qualifies to receive credit for direct exits or for two remote exits. To receive credit for direct exits or for two remote exits, there must be either a protected egress route or two remote routes from the occupants use area.

7.3 Worksheets for Evaluating Fire Safety for a Small Facility. A small facility is normally one with a capacity for 16 or fewer residents. For each individual residence or apartment used as a small board and care facility, the seven-step process in Figure 7.3 should be followed when evaluating fire safety.

7.3.1 Step 1 — Complete Cover Sheet Using Worksheet 7.3.1. See Figure 7.3.

7.3.2 Step 2 — Determine Safety Parameter Values Using Worksheet 7.3.2. Select and circle the safety value for each safety parameter in Worksheet 7.3.2 that best describes the conditions in the facility. Choose only one value for each of the eight parameters. If two or more values appear to apply, choose the one with the lowest point value.

7.3.3 Step 3 — Complete Individual Safety Evaluation Using Worksheet 7.3.3. The following steps should be taken:

(1) Transfer each of the eight circled safety parameter values from Worksheet 7.3.2 to every available block in the line with the corresponding safety parameter in Worksheet 7.3.3. Where the block is marked "÷ 2 =," enter one-half the value from Worksheet 7.3.2.
(2) Add each of the four columns, keeping in mind that any negative numbers need to be deducted.
(3) Transfer the resulting values for S_1, S_2, S_3, and S_4 to the corresponding blocks in Worksheet 7.3.5.

7.3.4 Step 4 — Determine Mandatory Requirements Using Worksheet 7.3.4A or 7.3.4B as appropriate. The following steps should be taken:

(1) Select the level of requirements from Worksheet 7.3.4A or 7.3.4B as appropriate. Circle the appropriate values.
(2) Transfer the circled values from Worksheet 7.3.4A or 7.3.4B to the corresponding blocks for S_a, S_b, S_c, and S_d in Worksheet 7.3.5.

7.3.5 Step 5 — Determine the Equivalency Evaluation. The following steps should be taken:

(1) Perform the subtractions indicated in Worksheet 7.3.5. Enter the differences in the appropriate answer blocks.
(2) For each row, check "yes" if the value in the answer block is zero (0) or greater. Check "no" if the value in the answer block is a negative number.

7.3.6 Step 6 — Evaluate Other Considerations Not Previously Addressed, Using Worksheet 7.3.6. The equivalency covered by Worksheets 7.3.2 through 7.3.5 includes the majority of the considerations covered by the *Life Safety Code*. Some considerations are not evaluated by this method and must be considered separately. These additional considerations are covered in Worksheet 7.3.6, Facility Fire Safety Requirements Worksheet. Complete one copy of this separate worksheet for each facility.

7.3.7 Step 7 — Determine Equivalency Conclusion. Conclude whether the level of life safety is at least equivalent to that prescribed by the *Life Safety Code*, using Worksheet 7.3.7, Conclusions. Worksheet 7.3.7 combines the zone fire safety equivalency evaluation of Worksheet 7.3.5 and the additional considerations of Worksheet 7.3.6.

7.4 Glossary for Fire Safety Evaluation Worksheet for a Large Facility.

7.4.1 Introduction. This glossary is provided to assist in completing the "Fire Safety Evaluation Worksheet for a Large Facility" to determine the suitability of a large facility to house a board and care occupancy. The instructions for the mechanisms of completing the worksheet are included in Section 7.5. They are not repeated in this glossary. This glossary provides expanded discussion and definitions for the various items in the worksheet to assist the user where questions of definition or interpretation arise. To the maximum extent possible, the glossary does not repeat the definitions already existing in NFPA *101* but rather references the appropriate paragraphs in NFPA *101*.

7.4.2 Areas of Application.

7.4.2.1 The entire residence is evaluated on one set of worksheets to the degree indicated by each item on the worksheets. See Worksheets 7.5.1 through 7.5.7. However, spaces that are not used for living units, not in direct utility or maintenance support of the living units, not provided for resident use, or not in any way involved in resident emergency egress shall be

WORKSHEET 7.3.1 COVER SHEET

Fire Safety Evaluation Worksheet for a Small Board and Care Facility

Facility Identification ______________________________

Evaluator ______________________ Date ______________________

WORKSHEET 7.3.2 SAFETY PARAMETER VALUES — SMALL FACILITY

Safety Parameters	Parameter Values		
1. Construction/ Fire Resistance	Exposed Structural Members	Protected 15 min	Protected 1 hr
	0	1	3
2. Hazardous Areas	Double Deficiency	Single Deficiency	None or No Deficiency
	−7	−4	0
3. Manual Fire Alarm	None or Incomplete	W/O F.D. Notification	W/ F.D. Notification
	0	1	2

Safety Parameters	Parameter Values				
4. Smoke Detection and Alarm	None or Incomplete	Single Lev. Det./ Limited Warning	Warning to All Bedrooms: Every Lev. Det.[e]	Warning to All Bedrooms: Every Lev. Plus Det. in Each Bdrm.	Total Coverage System
	−4	0	2	3(4)[f]	4

Safety Parameters	Parameter Values		
5. Automatic Sprinklers	Nonsprinklered	Standard Sprinklers	Quick-Response or Residential Sprinklers
	0	8	10
6. Interior Finish	Flame-Spread Ratings		
	>75 to ≤200	>25 to ≤75	≤25
	−3	−1	0

Safety Parameters	Unprotected Vertical Openings			Protected Vertical Openings[d]					
7. Separation of Sleeping Rooms (from other levels and from corridors)	None or Incomp.	Smoke Resisting W/O Closers	Smoke Resisting W/ Closers	None or Incomp.	Smoke Resisting	½ hr	½ hr Auto-Closing	Smoke Res. W/ Door Closer	½ hr W/ Door Closer
	−6	−4	0(0)[c]	−2	0	1(0)[a]	2(0)[a]	1	2(1)[a]

Safety Parameters		<2 Remote Routes: W/O Alt. Means	<2 Remote Routes: W/ Alt. Means	2 Remote Routes Unseparated	2 Remote Routes Separated	Direct Exit from Each Bdrm.
8. Means of Escape	Means of Escape on All Sleeping Levels	−1	0	1(0)[b]	2(0)[b]	3(0)[b]

Safety Parameters		Primary Route Not Protected: <2 Remote Routes, W/O Alt. Means	Primary Route Not Protected: <2 Remote Routes, W/ Alt. Means	Primary Route Not Protected: 2 Remote Routes	Primary Route Protected: <2 Remote Routes, W/O Alt. Means	Primary Route Protected: <2 Remote Routes, W/ Alt. Means	Primary Route Protected: 2 Remote Routes
8. Means of Escape	Means of Escape Not on All Sleeping Levels	−4	−3	0	−1	0	2(0)[b]

[a] Use ( ) if Parameter 1 is 0 and Parameter 5 is 0.
[b] Use (0) if Parameter 7 is based on a “none or incomplete” situation.
[c] Use (0) if door is 20-minute and has automatic closer.
[d] Consider a single-level building as having protected vertical openings.
[e] Every level detection is permitted to be omitted with quick-response automatic sprinklers throughout; however, detection in each bedroom is required.
[f] Use (4) in existing buildings if detection in each bedroom and quick-response automatic sprinklers throughout.

(For use with NFPA 101A-2016/NFPA *101*-2015, B & C Small) (p. 1 of 3)

WORKSHEET 7.3.6 FACILITY FIRE SAFETY REQUIREMENTS WORKSHEET

Considerations	Met	Not Met
Complies with the applicable requirements of Sections 32.7 and 33.7 (NFPA *101*).		

WORKSHEET 7.3.7 CONCLUSIONS

1. ☐ All of the checks in Worksheet 7.3.5 are in the “Yes” column and all applicable considerations in Worksheet 7.3.6 are identified as “Met”. The level of fire safety is at least equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for small residential board and care occupancies.

2. ☐ All of the checks in Worksheet 7.3.5 are in the “Yes” column and all considerations identified in Worksheet 7.3.6 as “Not Met” have been evaluated and mitigated to the satisfaction of the AHJ. The level of fire safety is at least equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for small residential board and care occupancies.

3. ☐ One or more of the checks in Worksheet 7.3.5 are in the “No” column or any consideration identified in Worksheet 7.3.6 as “Not Met” has NOT been evaluated and mitigated to the satisfaction of the AHJ. The level of fire safety is not shown by this system to be equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for small residential board and care occupancies.

(For use with NFPA 101A-2016/NFPA *101*-2015, B & C Small) (p. 3 of 3)

FIGURE 7.3 ***Continued***

permitted to be omitted from the calculation where such space is separated from all of the resident spaces and resident-support spaces by 2-hour fire resistance–rated construction (including any building members that support the resident areas and emergency egress routes). In such a case, however, any appropriate charges under Safety Parameter 2, "Hazardous Areas," in Worksheet 7.5.2 shall be charged. Also, the assignment of values for Safety Parameter 3, "Manual Fire Alarm"; Safety Parameter 7, "Exit System"; and Safety Parameter 8, "Exit Access," shall not consider conditions in unoccupied spaces that do not involve any egress paths.

7.4.2.2 Note that zoning of buildings shall be permitted, and individual zones shall be permitted to have different safety values (levels). Such zoning shall, however, be limited to considerations of differences in Safety Parameters 6, 7, and 8, which cover exits and separation of sleeping areas. Zoning shall be by separate fire/smoke zones. A fire/smoke zone is a portion of the building separated from all other portions of the building by building construction having at least a 1-hour fire resistance rating or smoke barriers, or both, conforming to the requirements of Section 8.5 of NFPA *101* using smoke barriers of at least a ½-hour fire resistance rating. Zoning of the facility also shall be permitted in non–fire-resistive sprinklered buildings, provided the construction separating one zone from another is sound- and smoke-resistant.

7.4.3 Maintenance. All protection systems, requirements, arrangements, and procedures shall be maintained in a dependable operating condition, and a sufficient state of readiness, and shall be used in such a manner that the intended safety function or hazard constraint is not impaired. Otherwise, they shall receive no credit in the evaluation.

7.4.4 Safety Parameters (Worksheet 7.5.2). The safety parameters are a measure of those building factors that bear on or contribute to the safety of those persons who might be in the building at the time of a fire. Each of the safety parameters is to be analyzed, and the safety value for each parameter that best describes the condition in the building is to be identified. Only one value for each of the parameters is to be chosen. If two or more values appear to apply, the one with the lowest point value shall be used.

7.4.4.1 Construction.

7.4.4.1.1 Number of stories in height is defined in 4.6.3 (NFPA *101*).

7.4.4.1.2 Where the facility includes additions or connected structures of different construction, the rating and classification of the structure shall be based on the following:

(1) Separate buildings where a 2-hour or greater fire resistance–rated separation exists between the portions of the building
(2) The lower safety parameter point score involved where such a separation does not exist

7.4.4.1.3 The safety parameter values for Type V(000), Type III(200), and Type II(000) receive a higher parameter credit if the building is fully sheathed. This credit is to be given if all portions of the bearing walls, bearing partitions, floor construction, and roofs [or a roof/loft system if the space above the highest ceiling is inaccessible and either is provided with draft stops or other barriers on 30 ft (9.1 m) spacing or is provided with heat- or smoke-actuated fire detectors that sound the building fire alarm], and all columns, beams, girders, trusses, or similar bearing members either have an inherent fire resistance or are sheathed, encased, or otherwise treated to provide approximately a ½-hour or greater fire resistance rating. Buildings fully sheathed with sound lath and plaster, gypsum board, or equivalent sheathing are considered as meeting these criteria.

7.4.4.2 Hazardous Areas. The assignment of parameter values for hazardous areas is a four-step process.

7.4.4.2.1 Step 1 — Identify Hazardous Areas. Hazardous areas are those having a degree of hazard greater than that normal to the general occupancy of the building, such as areas for storage of combustibles or flammables, for heat-producing appliances, or for maintenance purposes.

7.4.4.2.2 Step 2 — Determine the Level of Hazard.

7.4.4.2.2.1 There are two levels of hazard: structurally endangering and not structurally endangering.

(A) Structurally Endangering. A hazardous occupancy with sufficient fire or explosion potential to defeat the basic integrity of the building framing as defined in 7.4.4.1.

(B) Not Structurally Endangering. A hazardous occupancy with sufficient fire potential to build to full involvement and present a danger of propagating through openings or wall partitions but not possessing sufficient total potential to endanger the structural framing or floor decking as defined in 7.4.4.1.

7.4.4.2.2.2 Table 7.4.4.2.2.2 provides an analysis of typical types of hazardous areas relative to inherent potential structural danger to different classes of structural systems.

7.4.4.2.3 Step 3 — Determine the Fire Protection Provided.

7.4.4.2.3.1 The parameter value for hazardous areas is based on the presence or absence of the fire protection necessary to control or confine the hazard. Two different types of fire protection are considered. The first consists of automatic sprinklers or other appropriate extinguishing systems covering the entire hazard. The second is a complete fire resistance–rated enclosure, including the separation of the hazardous area from any bearing members, partitions separating the hazardous area from all other spaces, and doors to the space sufficient to exceed the potential of the fire load involved. Any hazardous space that has either of these protection systems is classed as having single protection. Any hazardous space that is both fully enclosed — as described above— and sprinklered is classed as having both (i.e., double-level protection). On this basis, any hazardous area with a fuel load that has the potential of overwhelming the available structural capability could, as a minimum, have a single deficiency as determined in 7.4.4.2.4.

7.4.4.2.3.2 Note that where the hazardous area is within a living unit or abuts an egress route (exit or exit access) addressed in 7.4.4.7 and 7.4.4.8, the credit for sprinklers shall not be permitted unless the hazardous area is separated from the rest of the living unit or the egress route by reasonably smoke-resisting barriers and doors.

7.4.4.2.4 Step 4 — Determine Degree of Deficiency and Assign Parameter Values. The parameter value ultimately is determined by the degree of the deficiency of the hazardous area based on the level of protection needed. Table 7.4.4.2.4 provides a matrix to be used for determining the degree of deficiency to be assessed. In some situations, more than one

Table 7.4.4.2.2.2 Hazardous Areas — Level of Hazard

Large Facility — Inherent Structural Danger from Typical Hazardous Areas			
Exposure (area, space, activity, condition)	Minimum Fire Resistance Rating of Bearing Walls, Bearing Partitions, Columns, Beams, Girders, Trusses, and Floor/Ceiling Assemblies Exposed to Hazardous Area		
	≥2 hours	≥1 hour to <2 hours	<1 hour
Occupational therapy space	N/SE	Varies*	SE
Craft shop	N/SE	Varies*	SE
General storage area	N/SE	Varies*	SE
Garage	N/SE	N/SE	SE
Boiler, heater, or incinerator rooms	N/SE	Varies*	SE
Fuel storage	N/SE	SE	SE
Trash chutes	N/SE	SE	SE
Trash rooms	N/SE	SE	SE
Small trash collection room	N/SE	N/SE	SE
Laundries (institutional type)	N/SE	N/SE	SE
Repair shops	N/SE	Varies*	SE

N/SE: not structurally endangering. SE: structurally endangering.
*Must be judged on the combustibles involved in the individual situation.

hazardous area with the same or differing levels of deficiency exists. The overall parameter value then is based on the single most serious deficiency for the hazardous area.

7.4.4.3 Manual Fire Alarm. Fire alarms are defined in 7.4.4.3.1 through 7.4.4.3.3.

7.4.4.3.1 None or Incomplete. There is no fire alarm system, or the system is incomplete and does not meet the requirements for a higher-scored category.

7.4.4.3.2 Without Fire Department Notification (W/O F.D. Notification). There is a fire alarm system that meets the requirements of 32.3.3.4 and 33.3.3.4 (NFPA *101*), as appropriate.

7.4.4.3.3 With Fire Department Notification (W/ F.D. Notification). There is a fire alarm system that complies with 7.4.4.3.2 and automatically transmits a signal to the fire department in accordance with 9.6.4 (NFPA *101*).

7.4.4.4 Smoke Detection and Alarm. All references to detectors herein refer to smoke detectors. No credit is given for thermal detectors in habitable spaces except as specifically noted. Heat detectors can be credited in uninhabitable spaces where ambient temperatures can be expected to exceed 120°F (50°C) or fall below 0°F (–18°C) (such as in unfinished attics or cocklofts), provided separation from inhabited spaces is at least ½-hour fire resistance–rated. The categories under this parameter are described in 7.4.4.4.1 through 7.4.4.4.4.

7.4.4.4.1 None or Incomplete. There are no detectors, or those that are present do not meet the requirements for a higher-scored category.

7.4.4.4.2 Single-Station Units in Each Bedroom. There is one single-station detector (sounds the alarm only at the responding detector) in each bedroom or sleeping room.

7.4.4.4.3 Interconnected System. Interconnected systems are those systems where the operation of any detector sounds alarm devices that alert all of the occupants. The alarm sounding device shall be permitted to be on other interconnected detectors or be other separate alarm devices. Where the systems are of the total building variety, the credit shall be permitted to be given only if the system includes manual fire alarm features or the building has a manual fire alarm system and the operation of the detection system sounds the manual fire alarm as though a fire alarm box on that story had been operated.

7.4.4.4.3.1 Corridors and Common Spaces Without Bedroom/Suite Detectors. The system meets the requirements of 32.3.3.4.8 and 33.3.3.4.8 (NFPA *101*).

7.4.4.4.3.2 Corridors and Common Spaces with Single-Station Bedroom/Suite Detectors. There is one single-station detector

Table 7.4.4.2.4 Hazardous Areas — Degree of Deficiency

	No protection	Sprinkler protection	Fire resistance–rated enclosure	Sprinklered and fire resistance–rated enclosure
Not structurally endangering	Single deficiency	No deficiency		
Structurally endangering	Double deficiency	Single deficiency	No deficiency* Double deficiency†	No deficiency* Single deficiency†

*If fire resistance and structural strength exceed maximum potential of hazard.
†If fire resistance and structural strength are not sufficient to withstand potential of hazard.

in each bedroom or sleeping room and interconnected detectors in corridors and common spaces that are spaced as described in 7.4.4.4.3.1.

7.4.4.4.3.3 Corridors and Common Spaces with Interconnected Bedroom/Suite Detectors. The system is as in 7.4.4.4.3.2, except bedroom/suite detectors are interconnected with corridor/common space detectors. In buildings in which construction as specified in 7.4.4.1 is based on all members having a fire resistance rating of at least ½ hour or more, a system as described in 7.4.4.4.3.2 that also has a thermal detector in each bedroom/suite connected to the building fire alarm system shall be permitted to be credited in this category.

7.4.4.4.4 Total Building System. This system includes detectors located in every bedroom throughout the building and also provides detector coverage throughout all corridors, common spaces, and hazardous areas, with the system meeting the requirements for an automatic fire alarm system in accordance with *NFPA 72*.

7.4.4.5 Automatic Sprinklers. Any sprinkler installation that meets the requirements of 32.3.3.5 and 33.3.3.5 (NFPA *101*).

7.4.4.5.1 None or Incomplete.

7.4.4.5.1.1 No credit is given if there are no sprinklers or if sprinklers, though present, are not sufficient to qualify for one of the other categories specified herein.

7.4.4.5.1.2 Note that any space that is credited as being protected by automatic sprinklers and abuts a hazardous area judged deficient in accordance with 7.4.4.2 shall not be permitted to be considered as sprinkler protected unless the hazardous area also is sprinkler protected.

7.4.4.5.2 Bedrooms/Suites Only. All bedrooms/suites have sprinkler protection.

7.4.4.5.3 Corridors and Common Spaces. Sprinkler protection covers all of the corridors and public spaces that separate, directly expose, or are in the egress path from the bedrooms/suites (except fire resistance–rated, enclosed, noncombustible stairwells). Sprinklers shall be installed along the corridor ceiling, and, in addition, one sprinkler shall be installed opposite the center of and inside of any bedroom door opening onto the corridor.

7.4.4.5.4 Bedrooms/Suites, Corridors, and Common Spaces. Sprinkler protection meets the combined requirements for 7.4.4.5.2 and 7.4.4.5.3 and is equipped with an automatic alarm initiating device that activates the building manual fire alarm system or an alternate evacuation alarm.

7.4.4.5.5 Total Building. The building is totally sprinkler protected and is equipped with an automatic alarm initiating device that activates the building manual fire alarm system or an alternate evacuation alarm.

7.4.4.6 Separation of Sleeping Rooms from Exit Access. Separation of sleeping rooms from exit access is based on the wall partitions that make up the separation and the protection of the openings in those partitions.

7.4.4.6.1 The charge for "None or Incomplete" (Safety Parameter 6 in Worksheet 7.5.2) is assessed in any case where the separation of sleeping rooms from exit access is insufficient to meet any of the other classifications in this parameter.

7.4.4.6.2 Criteria for "Expectation of Door Closing."

7.4.4.6.2.1 Expectation — Not High. This credit is given if the requirements for "expectation — high" are not met.

7.4.4.6.2.2 Expectation — High. High expectation of a door closing (or being closed at time of fire) shall be considered to be met if the requirements of 32.3.3.6.5 and 33.3.3.6.6 (NFPA *101*) are met.

7.4.4.6.3 Smoke Resisting. Sleeping rooms are separated from corridors or other common spaces by walls, partitions, or other constructions that resist the passage of smoke. There are no louvers, transfer grilles, operable transoms, or other air passages penetrating the wall except properly installed heating and utility installations. Doors, in walls or partitions that separate sleeping rooms from corridors or other common spaces, resist the passage of smoke and are provided with latches, door closers, or other mechanisms suitable for keeping the doors tightly closed. Vision panels shall be permitted to be installed in doors or partitions without respect to glass type or size.

7.4.4.6.4 Half-Hour. The credit is given if the requirements of 32.3.3.6.3 through 32.3.3.6.6 and 33.3.3.6.3 through 33.3.3.6.6 (NFPA *101*) are met.

7.4.4.6.5 1-Hour Walls, 20-Minute Doors. Sleeping rooms are separated from corridors or other common spaces by walls or partitions and doors meeting the requirements of 7.4.4.6.4, and the walls and partitions have at least a 1-hour fire resistance rating.

Exception: Where doors meet the requirements of 7.4.4.6.4 and automatic sprinklers are provided on both sides of the door.

7.4.4.7 Exit System. Exit systems are the paths of travel from the facility to the outside. For the purposes of this parameter, however, only those exit routes used in fire drills in accordance with Sections 32.7 and 33.7 (NFPA *101*) shall be credited.

7.4.4.7.1 Exposed Route. An exit route is exposed if a segment of that route is the only available route for one or more residents and that segment of the exit route is not safeguarded by one of the following means:

(1) Separation from all other rooms or areas by walls and doors of equivalent separation to that credited in 7.4.4.6
(2) Protection of the other rooms or spaces by an automatic sprinkler system
(3) Protection of the other rooms or spaces by a smoke detection and alarm system connected to activate the building evacuation alarm; and where furnishings, finishes, and furniture, in combination with all other combustibles within the space, are of such minimum quantity and are so arranged that a fully developed fire is unlikely to occur
(4) Cooking faclities permitted to be open to the corridor in accordance with 32.3.3.8 or 33.3.3.8 (NFPA *101*).

7.4.4.7.2 Multiple Routes. Multiple routes exist where the occupants of any sleeping room have, either from the sleeping room or through access in a corridor adjacent to the sleeping room, a choice of two separate exit routes to the outside.

7.4.4.7.3 Deficient. An exit route is deficient if it fails to meet any of the applicable criteria in 32.3.2 and 33.3.2 (NFPA *101*), except those related to travel distances and dead ends. These conditions are evaluated separately in 7.4.4.8.

7.4.4.7.4 Without Horizontal Exit (W/O Horiz. Exit). An egress system is based on this charge if there are multiple routes that are not deficient but the arrangement does not include a horizontal exit as defined in 7.4.4.7.5, or that have an acceptable direct exit from each sleeping room as defined in 7.4.4.7.7.

7.4.4.7.5 With Horizontal Exit (W/ Horiz. Exit). The presence of a single horizontal exit meeting the criteria in 7.2.4 (NFPA *101*) on each story containing sleeping rooms shall be considered as sufficient criteria to meet this requirement, provided that the space created is of sufficient size to provide at least 3 ft^2 (0.28 m^2) of accessible space for all of the potential occupants already present in or evacuating to such space.

7.4.4.7.6 Smokeproof Enclosure. Credit for a smokeproof enclosure shall be permitted to be given for a stairway designed and tested in accordance with the requirements of 7.2.3 (NFPA *101*) for a smokeproof enclosure. To receive credit for a smokeproof enclosure, all exit stairs credited in Safety Parameter 7, "Exit System," and Safety Parameter 8, "Exit Access," of Worksheet 7.5.2 shall meet the smokeproof enclosure requirements.

7.4.4.7.7 Direct Exit.

7.4.4.7.7.1 To be credited for direct exits, each sleeping room shall have within that unit a door that opens to the exterior at grade level or onto an unenclosed exterior balcony with direct access to an exterior exit or smokeproof enclosure. Where such openings are directly onto grade in a location where any person egressing can move directly away from the building without further exposure, the credit for direct exit shall be permitted, even if there are no other exit routes from the involved living unit.

7.4.4.7.7.2 Note that this parameter value does not cover the charges for the dead-end conditions, travel distance, interior finish in the egress routes (exits or exit access), or enclosure of stairways or other exit routes that pass from story to story. These elements are covered separately in 7.4.4.8, 7.4.4.9, and 7.4.4.10.

7.4.4.8 Exit Access. Exit access is a measurement of the travel distance from the sleeping rooms to the outside or to any other point of safety as defined in Section 3.3 (NFPA *101*), whichever is shorter.

7.4.4.9 Interior Finish.

7.4.4.9.1 Classification of interior finish on walls and ceilings of the occupied space shall be in accordance with Section 10.2 (NFPA *101*). Choose the safety parameter value in Worksheet 7.5.2 based on the interior finish material provided. For example, if the interior wall finish material has a flame-spread index of between 25 and 75, do not take the parameter value associated with a flame-spread index of less than 25 regardless of the presence of automatic sprinkler protection. The mandatory values have been calibrated to take into consideration any sprinkler protection provided. Exposed portions of structural members complying with the requirements of Type IV(2HH) construction shall be permitted.

7.4.4.9.2 Interior wall and ceiling finish materials tested in accordance with NFPA 265 or NFPA 286 as permitted by Section 10.2 (NFPA *101*), and meeting the criteria established in Section 10.2 (NFPA *101*) for those test standards, shall be scored as Class A interior finish materials (flame spread ≤25).

7.4.4.9.3 Only floor coverings in the exit and exit access system are considered. For purposes of assigning the parameter values in Worksheet 7.5.2, such floor coverings are considered as having a flame-spread index ≤25 if they meet the requirements for Class I or Class II and as otherwise having a flame-spread index >75. Previously installed floor coverings shall be permitted, subject to the approval of the authority having jurisdiction.

7.4.4.9.4 No consideration is included in the safety parameter value for any interior wall or ceiling finish material with a flame-spread index greater than 200 as measured by ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*. Some materials, including foam plastics, high density polyethylene, and polypropylene, are not permitted to be tested in accordance with ASTM E84 and must be tested in accordance with NFPA 286 and must meet the acceptance criteria shown in 10.2 (NFPA *101*). Some materials, including asphalt-impregnated paper, are capable of inducing extreme rates of fire growth and rapid flashover. In any case involving these materials, the resultant hazard is considered beyond the capacity of this evaluation system and requires an individual fire hazard assessment. Note that plywood of $\frac{1}{4}$ in. (6 mm) or greater thickness should be considered as having a flame-spread index of ≤200.

7.4.4.10 Vertical Openings.

7.4.4.10.1 These values apply to vertical openings and penetrations, including exit stairways, ramps, and any other vertical exits, pipe shafts, ventilation shafts, duct penetrations, and laundry and incinerator chutes. The charge for vertical openings shall be based on the presence or lack of enclosure and the fire resistance rating of the enclosure, if provided.

7.4.4.10.2 A vertical opening or penetration shall be classified as open, provided any of the following conditions apply:

(1) It is unenclosed.
(2) It is enclosed but does not have doors.
(3) It is enclosed but has openings other than doorways.
(4) It is enclosed with cloth, paper, or similar materials without any sustained firestopping capabilities, except as permitted by 32.3.3.1 and 33.3.3.1 (NFPA *101*), as appropriate.

7.4.4.10.3 If a shaft other than a credited exit route (i.e., credited as one of the multiple routes required in 7.4.4.7.2 or in determining travel distance in 7.4.4.8) is enclosed on all stories but one and this results in an unprotected opening between that shaft and one, and only one, story, the parameter value assigned to that shaft shall be 0. If a required egress route is contained in that shaft, the parameter value shall be –2.

7.4.4.11 Smoke Control. Smoke control definitions are provided in 7.4.4.11.1 through 7.4.4.11.5.

7.4.4.11.1 None. There are no smoke barriers (or horizontal exits) on the story, the story is not served by a smokeproof enclosure, and there are no mechanically assisted smoke control systems serving the story.

7.4.4.11.2 Smoke Barrier. Smoke barriers consist of installations conforming to the requirements of 32.3.3.7 and 33.3.3.7 (NFPA *101*), as appropriate. The full value for the presence of smoke barriers is awarded where an existing separation is by smoke partitions complying with Section 8.4 (NFPA *101*) on stories used for sleeping by not more than 30 residents.

7.4.4.11.3 Mechanically Assisted Systems — by Story. Mechanically assisted smoke control on a corridor basis is a tested and accepted smoke control system initiated by a method of smoke detection that ensures operation of the smoke control system before significant smoke has entered into the corridor involved. One method of judging the acceptability of smoke control systems is contained in NFPA 92.

7.4.4.11.3.1 The mechanism must be capable of pressurizing the corridor sufficiently to prevent smoke from the room/suite or space of origin from entering the corridor during the entire course of the fire. Such a system must be able to hold back the smoke through the expected maximum severity of the fire. It also must be capable of exhausting smoke from the corridor based on the assumption that the emergency evacuation procedures and other activities involving the opening and closing of doors will cause occasional brief periods during which the smoke control system is overpowered.

7.4.4.11.3.2 This results in the movement of the smoke from the fire area into the corridor. (The exhausting of the smoke normally would be accomplished by having an exhaust fan of lower capacity than the fan supplying air for pressurization exhaust from the corridor. The net pressurization force would occur from the effect of the pressurizing fan minus the effect of the removal or purging fan.)

7.4.4.11.3.3 The corridor's pressurizing system could involve early warning smoke detection, automatic closing of all room/suite doors, sprinkler protection, or all three. Where these additional protection devices are provided to effect such a smoke control system, the individual credits for each of the involved protection devices are in addition to the credits for the smoke control system.

7.4.4.11.4 Mechanically Assisted Systems — by Zone. Mechanically assisted smoke control on a zone basis shall include a smoke barrier (or a horizontal exit) supported by a tested and accepted smoke control system to provide a pressure differential that assists in confining smoke to the compartment of origin. One method of judging the acceptability of smoke control systems is contained in NFPA 92. Special smoke control fans shall be permitted to be used, or special adjustments of the normal building air movement fans shall be permitted to be made.

7.4.4.11.5 Mechanically Assisted Systems — by Room/Suite. Mechanically assisted smoke control on a room/suite basis is a tested and accepted smoke control system so designed as to provide a mechanism of automatically controlled fans, smoke vent shafts, or a combination thereof to ensure a positive pressure differential that prevents intrusion of smoke into any room or suite not involved in fire. One method of judging the acceptability of smoke control systems is contained in NFPA 92. In this method, the rooms have a pressure differential higher than that of the corridor and of any room where fire has been detected. Such systems shall be so arranged that there is detection in each room or suite that prevents a room involved in fire from becoming positively pressurized.

7.5 Worksheets for Evaluating Fire Safety in a Large Facility. A large facility normally is one that has a capacity for more than 16 residents. For each such facility to be evaluated, the seven-step process in Figure 7.5 should be followed when evaluating fire safety.

7.5.1 Step 1 — Complete Cover Sheet Using Worksheet 7.5.1. See Figure 7.5.

7.5.2 Step 2 — Determine Safety Parameter Values, Using Worksheet 7.5.2. Select and circle the safety value for each safety parameter that best describes the conditions in the facility. Choose only one value for each of the 11 parameters. If two or more values appear to apply, choose the one with the lowest point value.

7.5.3 Step 3 — Complete Individual Safety Evaluations Using Worksheet 7.5.3. The following steps should be taken:

(1) Transfer each of the 11 circled safety parameter values from Worksheet 7.5.2 to every available block in the line with the corresponding safety parameter in Worksheet 7.5.3. Where the block is marked "÷ 2 =," enter one-half the value from Worksheet 7.5.2.
(2) Add each of the four columns, keeping in mind that any negative numbers need to be deducted.
(3) Transfer the resulting values for S_1, S_2, S_3, and S_4 to the corresponding blocks in Worksheet 7.5.5.

7.5.4 Step 4 — Determine Mandatory Requirements Using Worksheet 7.5.4A, 7.5.4B, or 7.5.4C. The following steps should be taken:

(1) Select the level of requirements from Worksheet 7.5.4A, 7.5.4B, or 7.5.4(C). Circle the appropriate values.
(2) Transfer the circled values from Worksheet 7.5.4A, 7.5.4B, or 7.5.4C to the corresponding blocks for S_a, S_b, S_c, and S_d in Worksheet 7.5.5.

7.5.5 Step 5 — Evaluate Equivalency. The following steps should be taken:

(1) Perform the subtractions indicated in Worksheet 7.5.5. Enter the differences in the appropriate answer blocks.
(2) For each row, check "yes" if the value in the answer block is zero (0) or greater. Check "no" if the value in the answer block is a negative number.

7.5.6 Step 6 — Evaluate Other Considerations Not Previously Addressed, Using Worksheet 7.5.6. The equivalency covered by Worksheets 7.5.2 through 7.5.5 includes the majority of the considerations covered by the *Life Safety Code*. Some considerations are not evaluated by this method and must be considered separately. These additional considerations are covered in Worksheet 7.5.6, Facility Fire Safety Requirements Worksheet. Complete one copy of this separate worksheet for each facility.

7.5.7 Step 7 — Determine Equivalency Conclusion. Conclude whether the level of life safety is at least equivalent to that prescribed by the *Life Safety Code*, using Worksheet 7.5.7, Conclusions. Worksheet 7.5.7 combines the zone fire safety equivalency evaluation of Worksheet 7.5.5 and the additional considerations of Worksheet 7.5.6.

7.6 Glossary for Fire Safety Evaluation Worksheet for an Apartment Building with Board and Care Occupancies.

7.6.1 Introduction. This glossary is provided to assist in completing Figure 7.7, Worksheets for Evaluating Fire Safety in an Apartment Building with Board and Care Occupancies, to determine the suitability of an apartment building to house a board and care occupancy. This is a two-step procedure. The first step is to evaluate the portion of the building used as a board and care home; the second step evaluates the remainder of the building. The instructions for completing Figure 7.7 are included in Section 7.7. They are not repeated in this glossary. This glossary provides expanded discussion and definitions for the various items in the worksheets to assist the user where questions of definition or interpretation arise. To the maximum extent possible, the glossary does not repeat the defini-

FIGURE 7.5 Worksheets for Evaluating Fire Safety in a Large Facility.

Worksheet 7.5.2 ***Continued***

11. Smoke Control	None	Smoke Barriers	Mechanically Assisted Systems: By Story W/O Part.	By Story W/ Part.	By Zone	By Rm./Suite
	0(2)[n]	2(2)[u]	2	3	3	4

[a] In existing facilities and for conversions, use (–1 × stories in height) if building is fully sheathed with plaster, gypsum board, or similar materials, but not < –2 if Parameter 5 is ≥8.
[b] Use ( ) if Parameter 1 is based on Type V(000), Type III(200), or Type II(000), if Note A does not apply, and if Parameter 5 is ≤4.
[c] Use ( ) if Parameter 1 is based on Type V(000), Type III(200), or Type II(000).
[d] Use ( ) if Parameter 7 is –6.
[e] Use ( ) if Parameter 6 is based on "none or incomplete," or "walls or doors" are ½-hour walls/20-minute doors and Parameter 5 is ≤4.
[f] Use ( ) for existing levels "prompt" and "slow" if Parameter 7 is 4 and building height is ≤3 stories.
[g] Rate separation as:
- In existing facilities, ½ hour (or actual rating, if greater) if Parameter 5 is ≥6.
- Smoke resisting if Parameter 1 is based on Type V(000), Type III(200), or Type II(000), if building is not fully sheathed per Note A, and if Parameter 5 is ≥4.

[h] Use 0 in 1-story building.

For SI units, 1 ft = 0.3048 m; 1 ft² = 0.092 m².

[i] Interconnected system covers corridors and common spaces plus indicated bedroom or suite detectors.
[j] Use ( ) if Parameter 5 is ≥6.
[k] Use ( ) in facilities where each bedroom/suite has occupant controlled personal security access locks.
[l] Use ( ) if separations between bedrooms/suites also meet criteria.
[m] Use ( ) if requirements for 33.3.3.6.1.2 (NFPA *101*) are met.
[n] Use ( ) if floor travel does not exceed 200 ft.
[p] Use (6) if facility protected throughout by quick-response automatic sprinklers, corridor and common space detectors, and bedroom/suite smoke alarms.
[q] Use (0) if Parameter 5 is ≥8.
[r] In new facilities, rate separation as ½-hour walls/20-minute doors, where doors are smoke resisting and walls are ½-hour fire resistance–rated if Parameter 5 is 10.
[s] Use (0) if Parameter 5 is 10.
[t] Use (– 1) if evacuation capability is impractical and fire-rated hazardous area separation barriers are not also smoke partitions.
[u] Use (2) if an existing separation is by smoke partition on stories used for sleeping by not more than 30 residents.

NP: Not permitted—system not usable while this condition exists.

WORKSHEET 7.5.6 FACILITY FIRE SAFETY REQUIREMENTS WORKSHEET

	Considerations	Met	Not Met	Not Applic.
A.	Utilities comply with the provisions of 32.3.6.1 and 33.3.6.1.			X
B.	Heating, ventilating, and air conditioning equipment comply with the provisions of 32.3.6.2 and 33.3.6.2, except for enclosure of vertical openings, which have been considered in Safety Parameter 10 of Worksheet 7.5.3.			X
C.	Elevators, dumbwaiters, and vertical conveyors comply with the provisions of 32.3.6.3 and 33.3.6.3.			
D.	Rubbish chutes, incinerators, and laundry chutes comply with the provisions of 32.3.6.4 and 33.3.6.4.			X
E.	Complies with the applicable requirements of Sections 32.7 and 33.7.			

All references are to NFPA *101*, *Life Safety Code.*

WORKSHEET 7.5.7 CONCLUSIONS

1. ☐ All of the checks in Worksheet 7.5.5 are in the "Yes" column and all applicable considerations in Worksheet 7.5.6 are identified as "Met". The level of fire safety is at least equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for large residential board and care occupancies.

2. ☐ All of the checks in Worksheet 7.5.5 are in the "Yes" column and all considerations identified in Worksheet 7.5.6 as "Not Met" have been evaluated and mitigated to the satisfaction of the AHJ. The level of fire safety is at least equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for large residential board and care occupancies.

3. ☐ One or more of the checks in Worksheet 7.5.5 are in the "No" column or any consideration identified in Worksheet 7.5.6 as "Not Met" has NOT been evaluated and mitigated to the satisfaction of the AHJ. The level of fire safety is not shown by this system to be equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for large residential board and care occupancies.

Notes:

(For use with NFPA 101A-2016/NFPA *101*-2015, B & C Large) (p. 4 of 4)

FIGURE 7.5 ***Continued***

tions already existing in NFPA *101* but rather references the appropriate paragraphs in NFPA *101*.

7.6.2 Areas of Application.

7.6.2.1 The entire apartment building is evaluated on a form to the degree indicated by each item on the worksheet. See Worksheet 7.7.1. However, spaces that are not used for living units, are not in direct utility or maintenance support of the living units, are not provided for tenant use, or are not in any way involved in resident emergency egress shall be permitted to be omitted from the calculation where such space is separated from all of the tenant and tenant-support spaces by 2-hour fire resistance–rated construction (including any members that bear the load of tenant-use space and with 1½-hour fire doors in any communicating opening). In such cases, however, any appropriate charges under 7.6.4.2 in Safety Parameter 2, "Hazardous Areas," in Worksheet 7.7.2 shall be charged.

7.6.2.2 The suitability of the apartment unit actually used as the board and care home is evaluated separately and shall be permitted to be evaluated before or after evaluating the suitability of the apartment building.

7.6.2.3 Where evaluating an apartment unit, consider the common corridor as equivalent to the outside where evaluating egress routes. Also, where evaluating egress routes, credit a window only if it can be used in an emergency evacuation.

7.6.3 Maintenance. All protection systems, requirements, arrangements, and procedures shall be maintained in a dependable operating condition and a sufficient state of readiness and shall be used in such a manner that the intended safety function or hazard constraint is not impaired. Otherwise, they shall receive no credit in the evaluation.

7.6.4 Safety Parameters (Worksheet 7.7.2). The safety parameters are a measure of those building factors that bear on or contribute to the safety of those persons who might be in the building at the time of a fire. Each of the safety parameters is to be analyzed, and the safety value for each parameter that best describes the condition in the building is to be identified. Only one value for each of the parameters is to be chosen. If two or more values appear to apply, the one with the lowest point value shall be used.

7.6.4.1 Construction. The construction parameter values are applied to the entire building as defined in 7.6.4.1.1 through 7.6.4.1.3.

7.6.4.1.1 In evaluating the construction values, the height of the building is the story height of the board and care dwelling unit relative to the level of exit discharge, regardless of the total height of the building, which is defined as *stories in height* in Section 3.3 (NFPA *101*) and 4.6.3 (NFPA *101*).

7.6.4.1.2 Where the facility includes additions or connected structures of different construction, the rating and classification of the structure shall be based on the following:

(1) Separate buildings where a 2-hour or greater fire resistance–rated separation exists between the portions of the building
(2) The lower safety parameter point score involved where such a separation does not exist

7.6.4.1.3 The safety parameter values for Type V(000), Type III(200), and Type II(000) receive a higher parameter credit if the building is fully sheathed. This credit is to be given if all portions of the bearing walls, bearing partitions, floor construction, roofs [or a floor/loft system if the space above the highest ceiling is inaccessible and either is provided with draft stops or other barriers on 30 ft (9.1 m) spacing or is provided with heat- or smoke-actuated fire detectors that sound the building fire alarm], and all columns, beams, girders, trusses, or similar bearing members either have an inherent fire resistance or are sheathed, encased, or otherwise treated to provide approximately a ½-hour or greater fire resistance rating. Buildings fully sheathed with sound lath and plaster, gypsum board, or equivalent sheathing are considered to meet this criterion.

7.6.4.2 Hazardous Areas. The hazardous area parameter applies to the entire building except the apartment(s) actually used for the residential board and care facility. The assignment of charges for hazardous areas is a four-step process.

7.6.4.2.1 Step 1 — Identify Hazardous Areas. Hazardous areas are those having a degree of hazard greater than that normal to the general occupancy of the building, such as areas for storage of combustibles or flammables, for heat-producing appliances, or for maintenance purposes.

7.6.4.2.2 Step 2 — Determine the Level of Hazard. There are two levels of hazard: structurally endangering and not structurally endangering.

7.6.4.2.2.1 Structurally Endangering. A hazardous occupancy with sufficient fire or explosion potential to defeat the basic integrity of the building framing as defined in 7.6.4.1.

7.6.4.2.2.2 Not Structurally Endangering. A hazardous occupancy with sufficient fire potential to build to full involvement and present a danger of propagating through openings or wall partitions but not possessing sufficient total potential to endanger the structural framing or floor decking as defined in 7.6.4.1.

7.6.4.2.3 Step 3 — Determine the Fire Protection Provided. The parameter value for hazardous areas is based on the presence or absence of the fire protection necessary to control or find the hazard. Two different types of fire protection are considered. The first consists of automatic sprinklers or other appropriate extinguishing systems covering the entire hazard. The second is a complete fire resistance–rated enclosure, including the separation of the hazardous area from any bearing members, partitions separating the hazardous area from all other spaces, and doors to the space sufficient to exceed the potential of the fire load involved. Any hazardous space that has either of these protection systems is classed as having single protection. Any hazardous space that is both fully enclosed — as described above — and sprinklered is classed as having double-level protection. On this basis, any hazardous area with a fuel load that has the potential of overwhelming the available structural capability could as a minimum have a single deficiency as determined in 7.6.4.2.4. Note that, where the hazardous area abuts an egress route (exit or exit access) addressed in 7.6.4.7 and 7.6.4.8, the credit for sprinklers shall not be permitted unless the hazardous area is separated from the rest of the living unit or the egress route by reasonably smoke-resisting barriers and doors.

7.6.4.2.4 Step 4 — Determine Degree of Deficiency and Assign Parameter Values. The parameter value ultimately is determined by the degree of the deficiency of the hazardous area based on the level of protection needed. Table 7.6.4.2.4 provides a matrix for determining the degree of deficiency to be assessed. In some situations, more than one hazardous area with the same or differing levels of deficiency exists. The overall charge is based on the single most serious deficiency for the hazardous area.

7.6.4.3 Manual Fire Alarm. Manual fire alarms are defined in 7.6.4.3.1 through 7.6.4.3.3.

7.6.4.3.1 None or Incomplete. There is no manual fire alarm system, or the system is incomplete and does not meet the requirements for a higher-scored category.

7.6.4.3.2 Without Fire Department Notification (W/O F.D. Notification). There is a manual fire alarm system, regardless of the number of stories or units, meeting the appropriate requirements of 30.3.4.1 through 30.3.4.3 (NFPA *101*) and those requirements applicable to existing Option 1 apartment buildings in 31.3.4.1 through 31.3.4.3 (NFPA *101*).

7.6.4.3.3 With Fire Department Notification (W/ F.D. Notification). There is a manual fire alarm system that complies with the requirements of 7.6.4.3.2 and, in addition, automatically transmits a signal to the fire department in accordance with 9.6.4 (NFPA *101*).

7.6.4.4 Smoke Detection and Alarm. These parameter values apply only to apartments other than the group residence and to the areas used for apartment corridors and other common spaces. A detection system as used herein is one based on the use of smoke detectors. No credit is given for thermal detectors.

7.6.4.4.1 None or Incomplete. There are no detectors, or, if any are present, they do not meet the requirements for a higher-scored category.

7.6.4.4.2 Interconnected Systems. Interconnected systems are those systems where the operation of any detector sounds alarm devices on other detectors, or other separate alarm systems, that are spread out sufficiently to alert all of the building occupants. Where the systems are of the total building variety, the credit shall be permitted to be given only if the building has a manual fire alarm system and the operation of the detection system sounds the manual fire alarm as though a fire alarm box on that story had been operated. Interconnected systems must provide sounding devices that are sufficient in location and loudness to ensure the awakening of persons who sleep normally.

7.6.4.4.2.1 Corridors and Common Spaces. This parameter applies to those situations where there is at least one detector spaced every 30 ft (9.1 m) in corridors and an additional detector in all common use spaces for each 900 ft^2 (83.6 m^2) or less of floor space on that story. Detectors shall be permitted to be omitted from common use spaces that comply with one of the following:

(1) They are both sprinklered and protected from any egress routes or area of refuge or staging that serves the board and care home by the use of automatic-closing doors operated by smoke detection or activation of the sprinkler system.
(2) They are separated from the egress route or area of refuge or staging in 7.6.4.4.2.1(1) by fire resistance–rated construction and by automatic-closing doors of sufficient fire resistance rating to withstand the maximum fire potential in the common space.

7.6.4.4.2.2 Corridors and Common Spaces plus Each Level of Living Units. To be credited in this category, detectors must be provided in both of the following locations:

(1) Each living unit such that there is one detector or more in each single-level living unit or one detector or more on each level of any multilevel living unit
(2) Corridors and common spaces in accordance with the requirements of 7.6.4.4.2.1

7.6.4.4.3 Total Building System. A dwelling has a total building system if it meets the requirements of 31.3.4.4 for Option 2 (NFPA *101*).

7.6.4.5 Automatic Sprinklers. The parameter values for automatic sprinklers are based on the protection of spaces outside the apartment used for group residences.

7.6.4.5.1 None or Incomplete. No credit is given if there are no sprinklers or if sprinklers, though present, are not sufficient to qualify for one of the other categories specified herein. Note that any space that is credited as being protected by automatic sprinklers and abuts a hazardous area judged deficient in accordance with 7.6.4.2 shall not be permitted to be considered as sprinkler protected unless that hazardous area also is sprinkler protected.

7.6.4.5.2 Corridors, Public Spaces. Sprinkler protection covers all of the corridors and public spaces that separate, directly expose, or are in the egress path from the living units (except fire resistance–rated, enclosed, noncombustible stairwells). Sprinklers shall be installed along the corridor ceiling, and, in addition, one sprinkler shall be installed opposite the center of and inside of any living unit door opening onto the corridor.

7.6.4.5.3 Living Units Only. All living units have sprinkler protection complying with the requirements for light hazard protection in NFPA 13,NFPA 13D, or NFPA 13R, as appropriate.

Table 7.6.4.2.4 Hazardous Areas — Degree of Deficiency

	No protection	Sprinkler protection	Fire resistance–rated enclosure	Sprinklered and fire resistance–rated enclosure
Not structurally endangering	Single deficiency	No deficiency		
Structurally endangering	Double deficiency	Single deficiency	No deficiency* Double deficiency†	No deficiency* Single deficiency†

*If fire resistance and structural strength exceed maximum potential of hazard.

†If fire resistance and structural strength are not sufficient to withstand potential of hazard.

7.6.4.5.4 Corridor and Habitable Space. Such space meets the combined requirements for 7.6.4.5.2 and 7.6.4.5.3.

7.6.4.5.5 Total Building. The building is totally sprinkler protected in accordance with Section 9.7 (NFPA *101*) and is equipped with an automatic alarm initiating device that activates the building manual fire alarm system. Credit for total sprinkler protection shall not be given unless the living unit used for board and care purposes also is provided with total sprinkler protection.

7.6.4.6 Separation of Board and Care Home Unit and Its Exit Route from Other Spaces.

7.6.4.6.1 This parameter applies to all living units abutting corridors that might be used or involved in the exit system or to any areas of refuge or staging servicing the board and care unit. The separation requirements also apply to any common wall partitions between the board and care unit and any other living unit in the building.

7.6.4.6.2 Separation of living units from each other and from common spaces shall be based on the wall partition that makes up the separation and the protection of the openings in those partitions.

7.6.4.6.3 Duct penetrations where the duct is open on only one side of the partition and is of sheet steel construction shall be considered as equivalent to doors having a fire protection rating of at least 20 minutes. Where there are duct openings on both sides of the partition, the opening shall be considered unprotected unless there is a fire damper in the duct opening or the duct otherwise meets the requirements for omission of fire dampers as specified in NFPA 90A.

7.6.4.6.4 The partition shall be considered as "none or incomplete" if it has unprotected openings (louvers, gaps, transfer grilles, plain glass windows, or plain glass transoms) between the floor and the ceiling. If openings exist above the ceiling level (or even if the partition stops at the ceiling level), the walls shall be considered as complete if the ceiling itself is a complete membrane (such as plasterboard or lath and plaster). In this case, the fire resistance rating shall be based on that of the wall or ceiling system, whichever is less.

7.6.4.6.5 Walls shall be considered to have less than a ½-hour fire resistance rating if they are not equivalent to ½ in. (13 mm) gypsum wallboard, on both sides of studs, that is well nailed or fastened to the studs with appropriate taping and finishing of joints and fasteners. Walls shall be considered to be equivalent to or greater than a 1-hour fire resistance rating if they are part of any of the established systems recognized as having 1-hour or more fire resistance in accordance with recognized tests or approved listings.

7.6.4.6.6 Doors shall be considered as "none or incomplete" if any living unit does not have a door, or if the living unit has a door but there is some mechanism or obstruction that prevents closing of the door or otherwise leaves a significant opening between the door and the corridor, or the door has open louvers, or the door has ordinary glass lights or transoms. Doors that have been blocked open by doorstops, chocks, tiebacks, or other devices that need manual unlatching or releasing action to close the door shall be classified as "none or incomplete." Doors that are not provided with a latch or other device suitable for keeping the door tightly closed also shall be classified as "none or incomplete." Note that ordinary glass lights shall not be considered as requiring the "none or incomplete" classification in locations where both sides of the glass light are protected by automatic sprinklers.

7.6.4.6.7 Doors shall be considered as having 20-minute or greater fire protection rating if they are of 1¾ in. (44 mm) thick solid bonded wood core construction or an arrangement of equivalent or greater stability in fire integrity. The thermal insulation capability of the door is not considered. Hollow steel or sheet steel doors, therefore, meet the 20-minute requirement.

7.6.4.6.8 Doors shall be considered automatic-closing if they are provided with either traditional self-closing mechanisms or release mechanisms actuated by smoke detectors. In the case of doors separating living units from each other or from common spaces, self-closing doors shall be permitted whether or not they are equipped with devices that can be used to hold them in the open position, provided the normal routine of the living unit is to keep the door closed, particularly after the occupants have retired for the night. Note that this parameter category does not cover the charges for dead-end conditions, travel distance, interior finish in the egress routes (exit or exit access), or enclosure of stairways or other egress routes that pass from story to story. These elements are covered separately in 7.6.4.8, 7.6.4.9, and 7.6.4.10.

7.6.4.6.9 A separation is considered standard (i.e., rated as equivalent to walls greater than 1 hour, doors greater than 20 minutes) if the fire resistance of the doors and walls is equivalent to that specified by Chapters 30 and 31 (NFPA *101*) for the protection level involved.

7.6.4.7 Exit System. This parameter applies to the entirety of the exit routes serving the group residence. Exit routes are the paths of travel from the living unit to the outside, using any of the types and arrangements described in Chapter 7 (NFPA *101*).

7.6.4.7.1 Multiple Routes. Multiple routes exist where the occupants of any living unit have a choice of two separate exit routes to the outside, using those types permitted by Section 30.2 or 31.2, as appropriate (NFPA *101*). Occupants have a choice of routes either from the living unit or through access in a corridor adjacent to the living unit. Single exit routes complying with 30.2.4.6, 31.2.4.5, or 31.2.4.6 (NFPA *101*) qualify as multiple routes. *[See 7.6.4.7.6 for facilities complying with the single exit route provisions of 30.2.4.4 or 31.2.4.4 (NFPA 101).]*

7.6.4.7.2 Deficient. An exit route is deficient if it fails to meet any of the applicable criteria covered by Chapter 7 (NFPA *101*). The exit system also is classed as deficient if a smoke barrier, as required by 30.3.7 or 31.3.7 (NFPA *101*), is not provided.

7.6.4.7.3 Without Horizontal Exit (W/O Horiz. Exit). An egress system is based on this charge if there are multiple routes that are not deficient but the arrangement does not include a horizontal exit as defined in 7.6.4.7.4 or have an acceptable direct exit from each living unit as defined in 7.6.4.7.6.

7.6.4.7.4 With Horizontal Exit (W/ Horiz. Exit). A single horizontal exit on each story containing living units shall be considered a horizontal exit if the space created is of sufficient size to provide at least 3 ft^2 (0.28 m^2) of accessible space for all of the potential occupants, including those already present in and those evacuating to such space. The details of horizontal exits also shall meet the requirements of 7.2.4 (NFPA *101*). A horizontal exit acts as a smoke barrier, and, where provided, is credited as both a smoke barrier in 7.6.4.11 and a horizontal exit in 7.6.4.7.

7.6.4.7.5 Smokeproof Enclosure. Credit for a smokeproof enclosure shall be permitted to be given if either the stairway so designated meets the requirements for a smokeproof enclosure specified in 7.2.3 (NFPA *101*) or the stairway has an acceptably designed smoke pressurization system maintaining a positive pressure in the stairwell sufficient to prevent intolerable contamination of the stairwell by smoke or other fire effects. To receive the credit for smokeproof enclosures, all exit stairs credited in 7.6.4.7 and 7.6.4.8 must meet the smokeproof enclosure requirement.

7.6.4.7.6 Direct Exit.

7.6.4.7.6.1 To be credited for direct exits, each living unit shall have within that unit a door that opens to the exterior at grade or onto an unenclosed exterior balcony with direct access to an unenclosed exterior exit or smokeproof enclosure. The credit for direct exit is applicable even if there are no other exit routes from the involved living unit and if the following apply:

(1) The opening is directly onto a grade.
(2) The exit is located so that any person egressing can move directly away from the building without further exposure.

7.6.4.7.6.2 Single exit routes complying with 30.2.4.4 or 31.2.4.4 (NFPA *101*) qualify as direct exits. *[See 7.6.4.7.1 for facilities complying with the single exit route provisions of 30.2.4.6, 31.2.4.5, or 31.2.4.6 (*NFPA *101).]* Existing buildings more than six stories in height with exterior exit access in accordance with 31.3.5.11.2 (NFPA *101*) qualify as having a direct exit.

7.6.4.8 Exit Access. This parameter applies only to the exit access route from the board and care home.

7.6.4.8.1 Exit access is a measurement of travel distance from the living unit to the outside or to an enclosed interior stairway or other exit (e.g., horizontal exit) or to a smoke barrier meeting the requirements in 7.6.4.11, whichever is shorter.

7.6.4.8.2 The charge for dead ends shall be made where any corridor affords access in only one direction to a required exit from the corridor. The calculation of the distance to determine the level of charge is the measurement from the centerline of the doorway exiting the living unit to the nearest point where a person has a choice of two directions or routes of egress.

7.6.4.9 Interior Finish (Egress Routes).

7.6.4.9.1 The interior finish within the living units is evaluated separately from the interior finish in the corridor and egress routes and other public space. Classification of interior wall and ceiling finish materials is based on the flame-spread index and smoke developed index measured in accordance with ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*. The requirements apply to interior wall and ceiling finish materials as described in Section 10.2 (NFPA *101*). Choose the safety parameter value in Worksheet 7.7.2 based on the interior finish material provided. For example, if the interior wall finish material has a flame-spread index of between 25 and 75, do not take the parameter value associated with a flame-spread index of less than 25 regardless of the presence of automatic sprinkler protection. The mandatory values have been calibrated to take into consideration any sprinkler protection provided. Exposed portions of structural members complying with the requirements of Type IV(2HH) construction shall be permitted.

7.6.4.9.2 Interior wall and ceiling finish materials tested in accordance with NFPA 265 or NFPA 286 as permitted by Section 10.2 (NFPA *101*), and meeting the criteria established in Section 10.2 (NFPA *101*) for those test standards, shall be scored as Class A interior finish materials (flame spread ≤25).

7.6.4.9.3 Only floor coverings in the exit and exit access system are considered. For purposes of assigning the parameter values in Worksheet 7.7.2, such floor coverings are considered as having a flame-spread index ≤25 if they meet the requirements for Class I or II and as otherwise having a flame-spread index >75. Previously installed floor coverings shall be permitted, subject to the approval of the authority having jurisdiction.

7.6.4.9.4 No consideration is included in the safety parameter value for any finish with a flame-spread index greater than 200 as measured by ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*. Some materials, including foam plastics, high density polyethylene, and polypropylene, are not permitted to be tested in accordance with ASTM E84 and must be tested in accordance with NFPA 286 and must meet the acceptance criteria shown in 10.2 (NFPA *101*). Some materials, including asphalt-impregnated paper, arecapable of inducing extreme rates of fire growth and rapid flashover. In any case involving these materials, the resultant hazard is considered beyond the capacity of this evaluation system and requires an individual fire hazard assessment. Note that plywood of ¼ in. (6 mm) or greater thickness should be considered as having a flame-spread index of ≤200.

7.6.4.10 Vertical Openings. This parameter applies to those portions of vertical openings exposing the story containing the group residence or the exit routes from an apartment.

7.6.4.10.1 These values apply to vertical openings and penetrations including exit stairways, ramps, and any other vertical exits, pipe shafts, ventilation shafts, duct penetrations, and laundry and incinerator chutes. The charge for vertical openings shall be based on the presence or lack of enclosure and the fire resistance rating of the enclosure, if provided.

7.6.4.10.2 A vertical opening or penetration shall be classified as open or incomplete provided any of the following conditions apply:

(1) It is unenclosed.
(2) It is enclosed but does not have doors.
(3) It is enclosed but has openings other than doorways.
(4) It is enclosed with cloth, paper, or similar materials without any sustained firestopping capabilities.

7.6.4.10.3 If a shaft other than a credited exit route (i.e., credited as one of the multiple routes required in 7.6.4.7.1 or in determining travel distance in 7.6.4.8.1) is enclosed on all stories but one, and this results in an unprotected opening between that shaft and one, and only one, story, the parameter value assigned to that shaft shall be 0. If a required egress route is contained in that shaft, the parameter value shall be –2.

7.6.4.11 Smoke Control. This parameter applies to the story containing the board and care home. Smoke control definitions are provided in 7.6.4.11.1 through 7.6.4.11.5.

7.6.4.11.1 None. There are no smoke barriers (or horizontal exits) on the story, the story is not served by a smokeproof enclosure, and there are no mechanically assisted smoke control systems serving the story.

7.6.4.11.2 Smoke Barriers. Smoke barriers are partitions extending across the entire width of the building or so arranged as to combine a partition in the corridor with existing building elements and subdividing partitions and walls to partition the building into two completely separate units. The smoke barrier must be equipped with doors in the corridor that are self-closing, closed upon detection by smoke detectors located at the door arches, or closed by smoke detector systems that have been credited with a six-point parameter value in 7.6.4.4. Smoke barriers also shall conform to the requirements of Section 8.5 (NFPA *101*). A horizontal exit acts as a smoke barrier and is credited as both a smoke barrier in 7.6.4.11 and a horizontal exit in 7.6.4.7.

7.6.4.11.3 Mechanically Assisted Automatic Systems — by Zone. Mechanically assisted smoke control systems protected on a zone basis shall include a smoke barrier (or a horizontal exit) supported by a mechanism of automatic control fans, smoke vent shafts, or a combination thereof to provide a pressure differential that assists in confining smoke to the compartment of origin. Fans shall be permitted to be special smoke control fans, or special adjustments of the normal building air movement fans shall be permitted to be made.

7.6.4.11.4 Mechanically Assisted Automatic Systems — by Unit. Mechanically assisted smoke control systems protected on a living unit basis are systems so designed as to provide a mechanism of automatically controlled fans, smoke vent shafts, or a combination thereof to ensure a positive pressure differential that prevents intrusion of smoke into any living unit not involved in fire. Therefore, the living unit has a pressure differential higher than that of the corridor and higher than that of any living unit where fire has been detected. Such systems shall be so arranged that the detection mechanism in each living unit prevents a fire-involved living unit from becoming positively pressurized.

7.6.4.11.5 Mechanically Assisted Automatic Systems — by Corridor. A mechanically assisted smoke control system protected on a corridor basis is a system initiated by a method of smoke detection that ensures operation of the smoke control system before significant smoke has entered into the corridor involved.

7.6.4.11.5.1 The mechanism must be capable of pressurizing the corridor sufficiently to prevent smoke from the living unit or space of origin from entering the corridor during the entire course of the fire. Such a system must be able to hold back the smoke through the expected maximum severity of the fire. It also must be capable of exhausting smoke from the corridor based on the assumption that the emergency evacuation procedures and other activities involving the opening and closing of doors will cause occasional brief periods during which the smoke control system is overpowered.

7.6.4.11.5.2 This results in the movement of the smoke from the fire area into the corridor. (The exhausting of the smoke normally would be accomplished by having an exhaust fan of lower capacity than that of the fan supplying air for pressurization exhaust from the corridor. The net pressurization force would occur from the effect of the pressurizing fan minus the effect of the removal or purging fan.)

7.6.4.11.5.3 The corridor's pressurizing system could involve early warning smoke detection, automatic closing of all living unit doors, sprinkler protection, or all three. Where these additional protection devices are provided to effect such a smoke control system, the individual credits for each of the involved protection devices are in addition to the credits for the smoke control system.

7.7 Worksheets for Evaluating Fire Safety in an Apartment Building with Board and Care Occupancies. For each apartment house containing one or more apartment units with a board and care occupancy, the seven-step process in Figure 7.7 should be followed when evaluating fire safety in an apartment building with board and care occupancies.

7.7.1 Step 1 — Complete Cover Sheet Using Worksheet 7.7.1. See Figure 7.7.

7.7.2 Step 2 — Determine Safety Parameter Values Using Worksheet 7.7.2. First, select and circle the safety value for each safety parameter in Worksheet 7.7.2 that best describes the conditions in the facility. Then, choose only one value for each of the parameters. If two or more values appear to apply, choose the one with the lowest point value.

7.7.3 Step 3 — Complete Individual Safety Evaluations Using Worksheet 7.7.3. The following steps should be taken:

(1) Transfer each of the 11 circled safety parameter values from Worksheet 7.7.2 to every available block in the line with the corresponding safety parameter in Worksheet 7.7.3. Where the block is marked "÷ 2 =," enter one-half the value shown in Worksheet 7.7.2.
(2) Add each of the four columns, keeping in mind that any negative numbers need to be deducted.
(3) Transfer the resulting values for S_1, S_2, S_3, and S_4 to the corresponding blocks in Worksheet 7.7.5.

7.7.4 Step 4 — Determine Mandatory Requirements Using Worksheets 7.7.4A through 7.7.4D. The following steps should be taken:

(1) Using the classifications of the building (i.e., "new" or "existing"), the building height, and the level of requirements established for small dwelling units, circle the appropriate value in each of the four columns in Worksheet 7.7.4A, 7.7.4B, 7.7.4C, or 7.7.4D as appropriate.
(2) Transfer the circled values from Worksheet 7.7.4A, 7.7.4B, 7.7.4C, or 7.7.4D to the corresponding blocks for S_a, S_b, S_c, and S_d in Worksheet 7.7.5.

7.7.5 Step 5 — Evaluate Fire Safety Equivalency. The following steps should be taken:

(1) Perform the subtractions indicated in Worksheet 7.7.5. Enter the differences in the appropriate answer blocks.
(2) For each row, check "yes" if the value in the answer block is zero (0) or greater. Check "no" if the value in the answer block is a negative number.

7.7.6 Step 6 — Evaluate Other Considerations Not Previously Addressed Using Worksheet 7.7.6. The equivalency covered by Worksheets 7.7.2 through 7.7.5 includes the majority of the considerations covered by the *Life Safety Code*. Some considerations are not evaluated by this method and must be considered separately. These additional considerations are covered in Worksheet 7.7.6, Facility Fire Safety Requirements Worksheet. Complete one copy of this separate worksheet for each facility.

	−6(0)[d]	−4(0)[d]	−2	−1	0	1	2

Safety Parameters	Flame-Spread Ratings		
9. Interior Finish (egress routes serving board & care home units)	>75 to ≤200	>25 to ≤75	≤25
	−3	−1	0

(Worksheet 7.7.2 continues)

(For use with NFPA 101A-2016/NFPA *101*-2015, B & C Apts.) (p. 1 of 4)

FIGURE 7.7 Worksheets for Evaluating Fire Safety in an Apartment Building with Board and Care Occupancies.

Worksheet 7.7.2 *Continued*

10. Vertical Openings	Open or Incomplete Enclosure			Enclosed [h]	
	Thru 5 or More Stories	3–4 Stories	2 Stories	<1 hour [f]	≥1 hour [f]
	−10	−7	−2	0	1(0)[b]

11. Smoke Control (serving stories having board & care home units)	None	Smoke Barriers	Mechanically Assisted Systems		
			By Zone	By Unit	By Corridor
	0(2)[l]	2	3	3	4

[a] Use (−1 × stories in height) if building is fully sheathed with plaster, gypsum board, or similar materials but not <−2 if Parameter 5 is 8.

[b] Use ( ) if Parameter 1 is based on Type V(000), Type III(200), or Type II(000), if Note [a] does not apply, and if Parameter 5 is × 4.

[c] Use ( ) if Parameter 1 is based on Type V(000), Type III(200), or Type II(000).

[d] Use ( ) if Parameter 7 is −6.

[e] Use ( ) if Parameter 6 is based on “None or Incomplete,” or “Walls or Doors” are ½-hr walls/20-min doors and Parameter 5 is × 4.

[f] ≥30 min in existing building.

[g] Use ( ) if hazardous area is on exit route or in refuge area serving group home unit.

[h] Use 0 in 1-story building.

[i] Use (2) in 1–3 story buildings with <12 living units.

[j] Use (3) if corridors and common spaces are protected by quick response sprinklers.

[k] Use (0) if Parameter 5 is 8.

[l] Use ( ) where exemptions of 31.3.7.1 through 31.3.7.5 (NFPA *101*) apply.

[m] Use (3) if in compliance with 30.3.4.2.2 and 30.3.4.3.5 (NFPA *101*).

For SI units, 1 ft = 0.3048 m; 1 ft² = 0.092 m².

WORKSHEET 7.7.3 INDIVIDUAL SAFETY EVALUATIONS — APARTMENT BUILDINGS

Safety Parameters	Fire Control (S_1)	Egress Provided (S_2)	Refuge Provided (S_3)	General Fire Safety Provided (S_4)
1. Construction				
2. Hazardous Areas		÷ 2 =		
3. Manual Fire Alarm	÷ 2 =

WORKSHEET 7.7.6 FACILITY FIRE SAFETY REQUIREMENTS WORKSHEET

	Considerations	Met	Not Met	Not Applic.
A.	Utilities comply with the provisions of 32.3.6.1 and 33.3.6.1.			X
B.	Heating, ventilating, and air conditioning equipment comply with the provisions of 32.3.6.2 and 33.3.6.2, except for enclosure of vertical openings, which have been considered in Safety Parameter 10 of Worksheet 7.7.2.			X
C.	Elevators, dumbwaiters, and vertical conveyors comply with the provisions of 32.3.6.3 and 33.3.6.3.			
D.	Rubbish chutes, incinerators, and laundry chutes comply with the provisions of 32.3.6.4 and 33.3.6.4.			X
E.	Complies with the applicable requirements of Sections 32.7 and 33.7.			

All references are to NFPA *101*, *Life Safety Code*.

WORKSHEET 7.7.7 CONCLUSIONS

1. ☐ All of the checks in Worksheet 7.7.5 are in the "Yes" column and all applicable considerations in Worksheet 7.7.6 are identified as "Met". The level of fire safety is at least equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for an apartment building to house residential board and care occupancies.

2. ☐ All of the checks in Worksheet 7.7.5 are in the "Yes" column and all considerations identified in Worksheet 7.7.6 as "Not Met" have been evaluated and mitigated to the satisfaction of the AHJ. The level of fire safety is at least equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for an apartment building to house residential board and care occupancies.

3. ☐ One or more of the checks in Worksheet 7.7.5 are in the "No" column or any consideration identified in Worksheet 7.7.6 as "Not Met" has NOT been evaluated and mitigated to the satisfaction of the AHJ. The level of fire safety is not shown by this system to be equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for an apartment building to house residential board and care occupancies.

(For use with NFPA 101A-2016/NFPA *101*-2015, B & C Apts.) (p. 4 of 4)

FIGURE 7.7 ***Continued***

7.7.7 Step 7 — Determine Equivalency Conclusion. Conclude whether the level of life safety is at least equivalent to that prescribed by the *Life Safety Code,* using Worksheet 7.7.7, Conclusions. Worksheet 7.7.7 combines the zone fire safety equivalency evaluation of Worksheet 7.7.5 and the additional considerations of Worksheet 7.7.6.

Chapter 8 Fire Safety Evaluation System for Business Occupancies

8.1 Introduction.

8.1.1 This chapter is part of an NFPA guide and, therefore, is not mandatory. The term *shall* in this chapter is used to indicate that if the provisions of the chapter are applied, the procedures mandated are to be followed to ensure the effectiveness of the evaluation system.

8.1.2 The Fire Safety Evaluation System (FSES) is a measuring system. It compares the level of safety provided by an arrangement of safeguards that differ from those specified in NFPA *101* to the level of safety provided in a building that conforms exactly with the details of the *Code*.

8.1.3 This chapter is provided to assist in completion of Figure 8.6, Worksheets for Evaluating Fire Safety in Business Occupancies. The step-by-step instructions for completion appear in the text of Section 8.6. This chapter provides expanded discussion and definition of the various items in the worksheet to assist the user when questions of definitions or interpretation arise. The chapter is organized to follow the format of the worksheet progressively.

8.2 Procedure for Determining Equivalency.

8.2.1 Evaluate the factors affecting either every fire zone or the building as a whole using Figure 8.6, Worksheets for Evaluating Fire Safety in Business Occupancies.

8.2.1.1 Zoning must divide the building into units that consist of one or more complete fire/smoke zones. A fire/smoke zone is a portion of a building that is separated from all other portions of the building by vertical or horizontal fire barriers having at least a 1-hour fire resistance rating or vertical smoke barriers conforming to the requirements of Section 8.5 (NFPA *101*), or a combination of both. Any vertical openings (shafts, stairs) involved also must provide 1-hour separation. In facilities completely protected by automatic sprinkler protection, these fire resistance requirements do not apply. The elements separating one zone from another, however, must be of sound- and smoke-resisting construction. Doors in zone separations must be either self-closing or equipped with automatic closers operated by smoke detectors.

8.2.1.2 Zones shall be permitted to be either adjacent to each other (e.g., separate wings or building sections) or above each other (e.g., stories or groups of stories).

8.2.1.3 Each zone containing spaces used for business occupancy can be evaluated using this system.

8.2.1.4 Each of the safety parameters is to be analyzed, and the safety value for each parameter that best describes the condition in the building is to be identified.

8.2.2 Using the Facility Fire Safety Requirements Worksheet (Worksheet 8.6.6), determine the acceptability of the general building systems (utilities, HVAC, elevator installations, standpipes and fire extinguishers, and rubbish chutes, incinerators, and laundry chute installations).

8.2.3 Equivalency is achieved if the building or fire/smoke zone evaluations show equivalency or better in each and every zone and the requirements of the Facility Fire Safety Requirements Worksheet (Worksheet 8.6.6) are met.

8.3 Glossary for Fire Safety Evaluation Worksheet for Business Occupancies.

8.3.1 Introduction. This glossary is provided to assist in completing the Worksheets for Evaluating Fire Safety in Business Occupancies. This glossary provides expanded discussion and definitions for the various items in the worksheets to assist the user where questions of definition or interpretation arise. To the maximum extent possible, the glossary does not repeat the definitions already existing in NFPA *101* but rather references the appropriate paragraphs in NFPA *101*.

8.3.2 Areas of Application.

8.3.2.1 The entire building can be evaluated on a single set of worksheets. The building might, however, be zoned by considering each zone separately or by using any convenient grouping of zones.

8.3.2.1.1 Charges for Safety Parameter 2, "Segregation of Hazards," in Worksheet 8.6.2, apply to any hazardous area in the zone being evaluated and to any hazardous area in zones adjacent to or below the zone being evaluated.

8.3.2.1.2 Where zones are located above each other, the value assigned to Parameter 1, "Construction," in Worksheet 8.6.2, in each zone is based on the highest story used for regular human occupancy in that "stack of zones" and the type of construction for that stack of zones.

8.3.2.1.3 The assignment of values for Safety Parameter 5, "Fire Alarm"; Parameter 9, "Exit Access"; and Parameter 10, "Egress Route," in Worksheet 8.6.2, does not consider conditions in unoccupied spaces in other zones where such are not involved in any egress paths.

8.3.2.1.4 The evaluation of Safety Parameter 10, "Egress Route," in Worksheet 8.6.2, includes those portions of any egress route that serve the zone being evaluated. Any exposures or deficiencies pertaining to any part of the egress route must be taken into account in the evaluation of the zone.

8.3.2.2 Zones that do not involve regular human occupancy are evaluated the same as those with regular human occupancy, with the following variations:

(1) Any such zone shall be permitted to be omitted from the numerical evaluation if both of the following conditions are met:
    (a) The zone is not involved in the egress route from any space with regular human occupancy.
    (b) The zone conforms to NFPA *101* requirements applicable to its use.
(2) Alternatively, such zones shall be permitted to be evaluated using this system, on the condition that any additional egress capabilities and arrangements appropriate to the specific use of the space are provided.

8.4 Maintenance. All protection systems, requirements, arrangements, and procedures shall be maintained in a dependable operating condition and a sufficient state of readiness and shall be used in such a manner that the intended safety function or hazard constraint is not impaired. Otherwise, they shall receive no credit in the evaluation.

8.5 Safety Parameters (Worksheet 8.6.2). The safety parameters are a measure of those building factors that bear on or contribute to the safety of those persons who might be in the building at the time of a fire. The safety parameters in Worksheet 8.6.2 are described in the following subsections.

8.5.1 Construction. Construction types are classified in accordance with the definitions of NFPA 220. Where the facility includes additions or connected structures of different construction, the rating and classification of the structure is based on one of the following:

(1) Separate buildings where the separation between the portions of the building is a fire barrier having at least a 1-hour fire resistance rating and any opening protectives have at least a 45-minute fire protection rating
(2) The lower safety parameter point score involved where such a separation does not exist

8.5.2 Segregation of Hazards. The assignment of charges for unsegregated hazardous areas is a four-step process.

8.5.2.1 Step 1 — Identify Hazardous Areas. A hazardous area is any space or compartment in which a storage or other activity exists that is not a part of normal office space arrangements and that possesses the potential for producing a fully involved fire.

8.5.2.2 Step 2 — Determine the Level of Hazard.

8.5.2.2.1 There are two levels of hazard: structurally endangering and not structurally endangering.

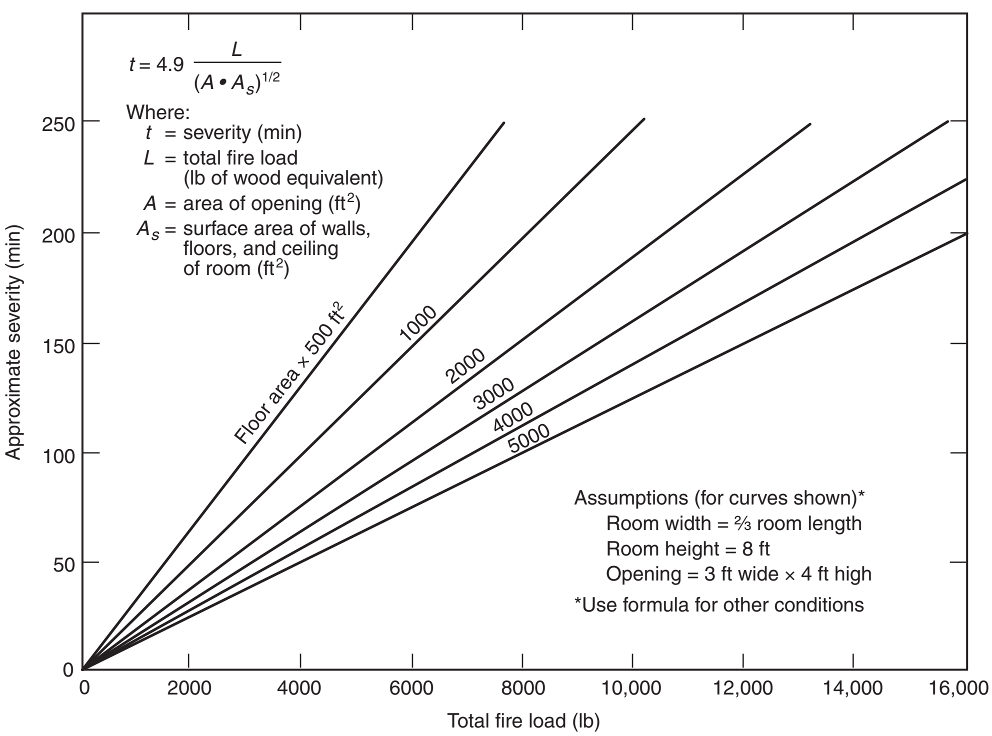
8.5.2.2.1.1 Structurally Endangering. A hazardous area with a potential fire severity that might exceed the tested resistance of the enclosure and defeat the basic structural integrity of the building framing as defined in Safety Parameter 1, "Construction," of Worksheet 8.6.2. *[See Figure 8.5.2.2.1.1 for determining approximate potential fire severity.]*

8.5.2.2.1.2 Not Structurally Endangering. A hazardous area with sufficient fire potential to build to full involvement (flashover) and present a danger of propagating through openings or wall partitions but not possessing sufficient total potential to endanger the structural framing or floor decking as defined in Safety Parameter 1 of Worksheet 8.6.2. *[See Figure 8.5.2.2.1.2 for assistance in estimating the fire size needed to flash over the area containing various combustible contents.]*

8.5.2.2.2 Example of Structurally Endangering. For a room 20 ft × 30 ft × 8 ft high (6.1 m × 9.1 m × 2.4 m high) with a (window) opening 3 ft wide × 4 ft high (0.9 m wide × 1.4 m high), 3000 lb (1361 kg) of ordinary fuel can produce a fire severity of approximately 95 minutes. If the fire resistance of the hazardous area enclosure is less than 95 minutes and the fire is likely to continue to its estimated duration, the hazardous area shall be permitted to be classed as structurally endangering.

8.5.2.3 Step 3 — Determine the Fire Protection Provided.

8.5.2.3.1 The parameter value for hazardous areas is based on the presence or absence of the fire protection necessary to control or confine the hazard. Two different types of fire protection are considered. The first consists of automatic sprinklers or other appropriate extinguishing systems covering the entire hazard. The credit for sprinklers shall not be given



For SI units, 1 lb = 0.4536 kg; 1 ft = 0.3048 m; 1 ft^2 = 0.0929 m^2.

FIGURE 8.5.2.2.1.1 Approximate Fire Severity.

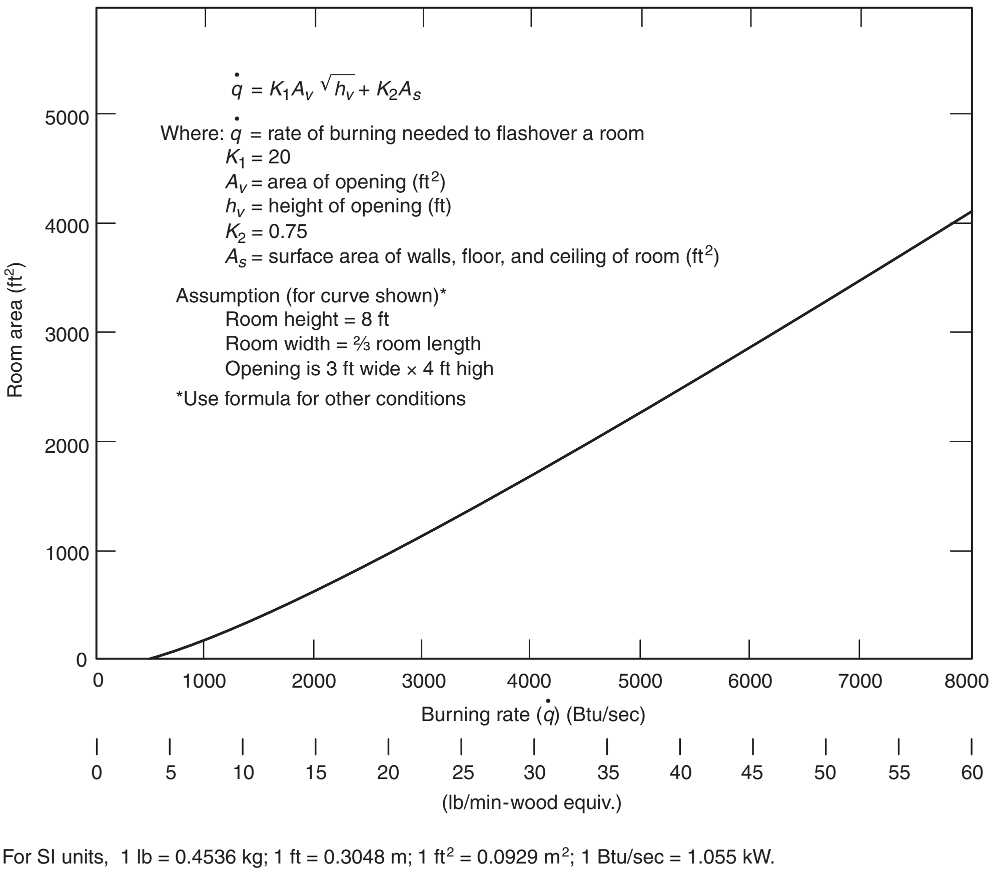


FIGURE 8.5.2.2.1.2 Approximate Flashover Energy.

unless the hazardous area is separated from the rest of human occupancy or the egress route by reasonably smoke-resistant partitions and doors. The second is a complete fire enclosure having a sufficient fire resistance rating to contain the potential fire severity of the hazardous area. This includes the following:

(1) The separation of the hazardous area from any structural framing members
(2) Partitions separating the hazardous area from all other spaces
(3) Fire protection–rated doors sufficient to exceed the potential of the fire load involved

8.5.2.3.2 Any hazardous space that has any of these protection systems is classified as having single protection.

8.5.2.4 Step 4 — Determine Degree of Deficiency and Assign Parameter Values.

8.5.2.4.1 The parameter value ultimately is determined by the degree of the deficiency of the hazardous area based on the level of protection needed. Table 8.5.2.4.1 provides a matrix to be used for determining the degree of deficiency to be assessed.

8.5.2.4.2 In some situations, more than one hazardous area with the same or differing levels of deficiency exists. The overall charge is based on the single most serious deficiency for the hazardous area.

Table 8.5.2.4.1 Segregation of Hazards — Degree of Deficiency

	No protection	Sprinkler protection	Fire resistance–rated enclosure*	Sprinklered and fire resistance–rated enclosure*
Not structurally endangering	Single deficiency	No deficiency		
Structurally endangering	Double deficiency	Single deficiency	No deficiency	

*Complete enclosure having sufficient fire resistance to contain the potential of the hazardous contents area.

8.5.2.4.3 Open-Plan Office Space.

8.5.2.4.3.1 A sprinkler-protected open-plan office space is not considered a hazardous space.

8.5.2.4.3.2 An unsprinklered open-plan office space is not considered a hazardous space unless it involves such a collection of fuel that flashover is likely to occur. This can be estimated in the following manner:

(1) Appraise the largest fuel concentrations. A fuel concentration is a collection of combustible materials (desks, files, or other material or items) that is separated from other fuel concentrations by a clear space that is 24 in. (610 mm) wide or one-half the height of the collection, whichever is greater. Floor covering is not considered in this estimate.
(2) The burning rate is based on the best available data. If test data are available, use those data; otherwise use Table 8.5.2.4.3.2. If data are not available and Table 8.5.2.4.3.2 is not sufficient, the burning rate is based on 125 Btu/sec · ft^2 of actual fuel-covered floor space for typical wooden desk modules. Ignore space occupied by metal desks or metal file cabinets. For open-shelf storage or similar piled or stacked concentrations of combustible materials, estimate 100 Btu/sec · ft^2 of covered floor space for each foot of height of combustible material. Double these figures for the portion of the fuel assembly that is foamed plastic.
(3) Based on the estimated burning rate, appraise the flashover potential. Use Figure 8.5.2.2.1.1.
(4) If flashover is shown as a potential, use Figure 8.5.2.2.1.2 to appraise severity, classify the space as a hazardous area, and assign charges, as appropriate.

8.5.3 Vertical Openings. These values apply to vertical openings and penetrations including exit stairways, ramps, and any other vertical exits, pipe shafts, ventilation shafts, duct penetrations, and laundry and incinerator chutes. The charge for vertical openings is based on the fire resistance of the enclosure, if provided. Where the protection of vertical openings (other than exits) meets the requirements of 38.3.1 and 39.3.1 (NFPA *101*), the parameter is assessed on the basis of "Enclosed, >1 hr" for new buildings >75 ft in height, and "Enclosed, 30 min to 1 hr" for all other buildings.

8.5.3.1 A vertical opening or penetration is classified as open if it has any of the following characteristics:

(1) Unenclosed
(2) Enclosed but has doorways (or similar portals) that are without doors
(3) Enclosed but has unprotected openings other than doorways
(4) Enclosed with cloth, paper, or similar materials without any sustained firestopping capabilities

8.5.3.2 The credit for vertical opening protection varies depending on the number of stories connected by the vertical opening and the degree of enclosure.

8.5.4 Sprinklers.

8.5.4.1 Where an automatic sprinkler is installed for either total or partial building coverage, the system shall be in accordance with the requirements of NFPA 13.

8.5.4.2 To receive credit for protection, the sprinkler system must be equipped with an automatic alarm initiating device that activates the building manual fire alarm system or otherwise sounds an alarm sufficiently audible to be heard in all occupied areas.

8.5.4.3 To receive credit for "total building" sprinkler protection, the entire building must be provided with sprinkler coverage and that coverage must cover all zones of the building.

8.5.5 Fire Alarm. Fire alarms are defined in 8.5.5.1 through 8.5.5.4.

8.5.5.1 None. There is no fire alarm system, or the system is incomplete and does not meet the requirements for a higher-scored category.

8.5.5.2 Without Fire Department Notification (W/O F.D. Notification). There is a fire alarm system that meets the requirements of Section 9.6 (NFPA *101*).

8.5.5.3 With Fire Department Notification (W/ F.D. Notification). There is a fire alarm system that complies with the requirements of 8.5.5.2 and, in addition, automatically transmits a signal to the fire department that is committed to serve the area in which the building is located through a direct connection, an approved central station, or other acceptable means.

8.5.5.4 With Voice Communication. There is a fire alarm system with voice alarm in accordance with 11.8.4 (NFPA *101*).

8.5.6 Smoke Detection.

8.5.6.1 All references to detectors herein refer to smoke detectors. No credit is given for heat detectors in habitable space except as specifically noted in 8.5.6.2 through 8.5.6.5. Heat detectors can be credited in uninhabitable spaces where ambient temperatures can be expected to reach 120°F (50°C) or fall below 0°F (–18°C), provided separation from inhabited spaces is at least ½-hour fire resistance–rated.

8.5.6.2 To meet the requirements for smoke detector coverage, the spaces must be provided with smoke detectors installed in accordance with *NFPA 72*.

8.5.6.3 Only those detectors whose activation will sound the alarm throughout the zone of origin are to be credited in this parameter.

8.5.6.4 If the building is evaluated by zones as defined in 8.3.2, the evaluation is based solely on detection within the zone.

8.5.6.5 To receive credit for smoke detection in corridors only, all corridors in the building or zone must have smoke detectors.

8.5.7 Interior Finish.

8.5.7.1 Classification of interior finish is based on the flame-spread index and smoke developed index of the interior wall and ceiling finish materials as tested in accordance with ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*. The requirements apply to wall and ceiling finish materials as described in Section 10.2 (NFPA *101*).

8.5.7.2 No consideration is included in the safety parameter value for any finish with a flame-spread rating of more than 200 as measured by ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*. Thus, this FSES should not be used where such conditions

Table 8.5.2.4.3.2 Some Typical Peak Rates of Heat Release

Btu/sec · ft^2	Growth Rate[a]	Potential Fuel
1.5	S	Fire retardant–treated mattress (including normal bedding)
15[b]	M	Lightweight Type C upholstered furniture[c]
35[b]	S	Moderate weight Type C upholstered furniture[c]
35	F	Mail bags (full) stored 5 ft high
50[b]	M	Cotton/polyester innerspring mattress (including bedding)
60[b]	M	Lightweight Type B upholstered furniture[c]
60[b]	S	Medium weight Type C upholstered furniture[c]
65[b]	VF	Methyl alcohol pool fire
70[b]	S	Heavy weight Type C upholstered furniture[c]
80[b]	F	Polyurethane innerspring mattress (including bedding)
90[b]	M	Moderate weight Type B upholstered furniture[c]
125	M	Wooden pallets 1½ ft high
145[b]	M	Medium weight Type B upholstered furniture[c]
150[b]	F	Lightweight Type A upholstered furniture[c]
150	F	Empty cartons 15 ft high
175[b]	M	Heavy weight Type B upholstered furniture[c]
175	F	Diesel oil pool fire (> about 3 ft diameter)
175	VF	Cartons containing polyethylene bottles 15 ft high
220[b]	F	Moderate weight Type A upholstered furniture[c]
225[b]	F	Particleboard wardrobe/chest of drawers
290	VF	Gasoline pool fire (> about 3 ft diameter)
340[b]	VF	Thin plywood wardrobe with fire-retardant paint on all surfaces (50 in. × 24 in. × 72 in. high)
350	F	Wooden pallets 5 ft high
360[b]	F	Medium weight Type A upholstered furniture[c]
450[b]	F	Heavy weight Type A upholstered furniture[c]
600[b]	VF	Thin plywood wardrobe (50 in. × 24 in. × 72 in. high)

For SI units, (Btu/sec)/ft^2 = 11.35 kW/m^2; 1 in. = 25.4 mm; 1 Btu/sec = 1.055 kW; 1 ft = 0.3048 m; 1 lb = 0.4536 kg; 1 ft^2 = 0.0929 m^2.

[a]Growth Rates:

S — Slow: Burning rate in the range of a *t*-squared fire that reaches 1000 Btu/sec in 600 seconds.

M — Moderate: Burning rate in the range of a *t*-squared fire that reaches 1000 Btu/sec in 300 seconds.

F — Fast: Burning rate in the range of a *t*-squared fire that reaches 1000 Btu/sec in 150 seconds.

VF — Very Fast: Burning rate in the range of a *t*-squared fire that reaches 1000 Btu/sec in 75 seconds.

[b]Peak rates of heat release were of short duration. These fuels typically showed a rapid rise to the peak and a corresponding rapid decline. In each case, the fuel package tested consisted of a single item.

[c]The classification system used to describe upholstered furniture is as follows:

Lightweight — Less than about 5 lb/ft^2 of floor area. A typical 6 ft long couch weighs under 75 lb.

Moderate weight — About 5 lb/ft^2 to 10 lb/ft^2 of floor area. A typical 6 ft long couch weighs between 75 lb and 150 lb.

Medium weight — About 10 lb/ft^2 to 15 lb/ft^2 of floor area. A typical 6 ft long couch weighs between 150 lb and 300 lb.

Heavy weight — More than about 15 lb/ft^2 of floor area. A typical 6 ft long couch weighs over 300 lb.

Type A — Furniture with untreated or lightly treated foam plastic padding and nylon or other melting fabric.

Type B — Furniture with untreated or lightly treated foam plastic padding or with nylon or other melting fabric, but not both.

Type C — Furniture with cotton or heavily treated foam plastic padding and having cotton or other fabric that resists melting.

The estimated heat release rates are based on furniture having simple lines. For ornate or convoluted shapes, increase the indicated rates by up to 50 percent based on elaborateness.

Additional potential fuel heat release information can be found in *NFPA 72*, NFPA 204, the *SFPE Handbook of Fire Protection Engineering*, and other references.

exist. Some materials, including foam plastics, high density polyethylene, and polypropylene, are not permitted to be tested in accordance with ASTM E84 and must be tested in accordance with NFPA 286 and must meet the acceptance criteria shown in 10.2 (NFPA *101*). Some materials, including asphalt-impregnated paper, are capable of inducing extreme rates of fire growth and rapid flashover. In any case involving these materials, the resultant hazard is considered beyond the capacity of this evaluation system and requires an individual fire hazard assessment.

8.5.7.3 Interior wall and ceiling finish materials tested in accordance with NFPA 265 or NFPA 286 as permitted by Section 10.2 (NFPA *101*), and meeting the criteria established in Section 10.2 (NFPA *101*) for those test standards, shall be scored as Class A interior finish materials (flame spread ≤25).

8.5.7.4 Any interior finish having a flame-spread index of 75 or less that is protected by automatic sprinklers is evaluated as having a flame-spread index not exceeding 25. Any interior finish having a flame-spread index of more than 75 but not more than 200 that is protected by automatic sprinklers is evaluated as having a flame-spread index not exceeding 75.

8.5.8 Smoke Control. Smoke control definitions are provided in 8.5.8.1 through 8.5.8.2.2.

8.5.8.1 No Control. There are no smoke barriers or horizontal exits to a separated fire/smoke zone on the story and no mechanically assisted smoke control systems serve the story.

8.5.8.2 Smoke Barriers. Smoke barriers consist of installations conforming to the requirements of Section 8.5 (NFPA *101*).

8.5.8.2.1 Passive. The smoke control system is passive if it consists of continuous vertical membranes designed to restrict the movement of smoke. Passive smoke barriers might or might not have a fire resistance rating and might have protected openings.

8.5.8.2.2 Active. The smoke control system is active if it has a tested and accepted smoke control system that obstructs the leakage of smoke between compartments or zones. One method of judging acceptance of smoke control systems is contained in NFPA 92.

8.5.9 Exit Access.

8.5.9.1 The charge for dead-end access is made where any corridor affords access in only one direction to a required exit.

8.5.9.2 If dead-end distances exceed 100 ft (30 m), a separate analysis must be made to evaluate the potential of flashover of any spaces that could block egress from the dead end and to determine the potential rate of smoke-filling of the egress system involved. If the safe time is shorter than the expected egress time, the evaluation should be discontinued unless a corrective action is specified.

8.5.9.3 The 50 ft (15 m) dead-end limit is applicable to existing buildings or new fully sprinklered buildings. A value of 20 ft (6.1 m) should be used for other new buildings.

8.5.9.4 Any system with common path of travel in excess of that permitted by NFPA *101* should be considered deficient under Safety Parameter 10, "Egress Route."

8.5.10 Egress Route.

8.5.10.1 Egress routes are the paths of travel from any point within a room to the public way using any types and arrangements described in Sections 38.2 or 39.2 (NFPA *101*).

8.5.10.2 Egress routes are defined in 8.5.10.2.1 through 8.5.10.2.5.

8.5.10.2.1 Single Egress Route. A single egress route exists where the occupants on any story do not have either a direct exit to the public way or multiple egress routes as defined in 8.5.10.2.2.

8.5.10.2.2 Multiple Egress Routes. Multiple egress routes exist where the occupants on a story have a choice of at least two separate means of egress routes to the public way using the permitted types in Sections 38.2 or 39.2 (NFPA *101*).

8.5.10.2.3 Deficient — Multiple Routes. An egress route is deficient if it fails to meet any of the applicable criteria of NFPA *101* including capacity. Any system with a common path of travel in excess of that permitted by NFPA *101* should be considered deficient under Parameter 10, "Egress Route."

8.5.10.2.4 Smokeproof Enclosure. Credit for a smokeproof enclosure shall be permitted to be given for a stairway designed and tested in accordance with the requirements of 7.2.3 (NFPA *101*) for a smokeproof enclosure. To receive credit for a smokeproof enclosure, all exit stairs credited in Safety Parameter 10, "Egress Route," shall meet the smokeproof enclosure requirements.

8.5.10.2.5 Direct Exit. To be credited for direct exits, each room shall have within that unit a door that opens to the exterior at grade level or onto an exterior balcony with direct access to an exterior exit. Where such openings are directly onto grade in a location where any person egressing can move directly away from the building without further exposure, the credit for direct exit shall be given even if there are no other exit routes from the space.

8.5.11 Corridor/Room Separation. The values assigned in Safety Parameter 11, "Corridor/Room Separation," are based on the quality of separation between the room and the corridor. For purposes of this evaluation, corridor separation in new buildings is considered as complete (i.e., 1 hour with door closer) if it meets the requirements of 38.3.6 (NFPA *101*).

8.5.11.1 Corridor/room separation is defined in 8.5.11.1.1 through 8.5.11.1.3.

8.5.11.1.1 Incomplete.

8.5.11.1.1.1 The separation is judged as "incomplete" if the wall to the corridor has unprotected openings (no door, or there are louvers, gaps, or transfer grilles) between the floor and ceiling. If openings exist above the ceiling level, the separation is considered complete if the ceiling in the room is a completed membrane. In this case, the separation rating is based on the level of resistance involved in the wall/ceiling system.

8.5.11.1.1.2 The score for incomplete separation is based on the potential time that at least the lower 5 ft (1.5 m) of the corridor could be expected to remain free of smoke if a fully involved fire were to occur in an exposing room. This is dependent on the amount of leakage from the exposing room with the greatest leakage and the size of the corridor *(see Figure 8.5.11.1.1.2)*. The scores are shown in Table 8.5.11.1.1.2.

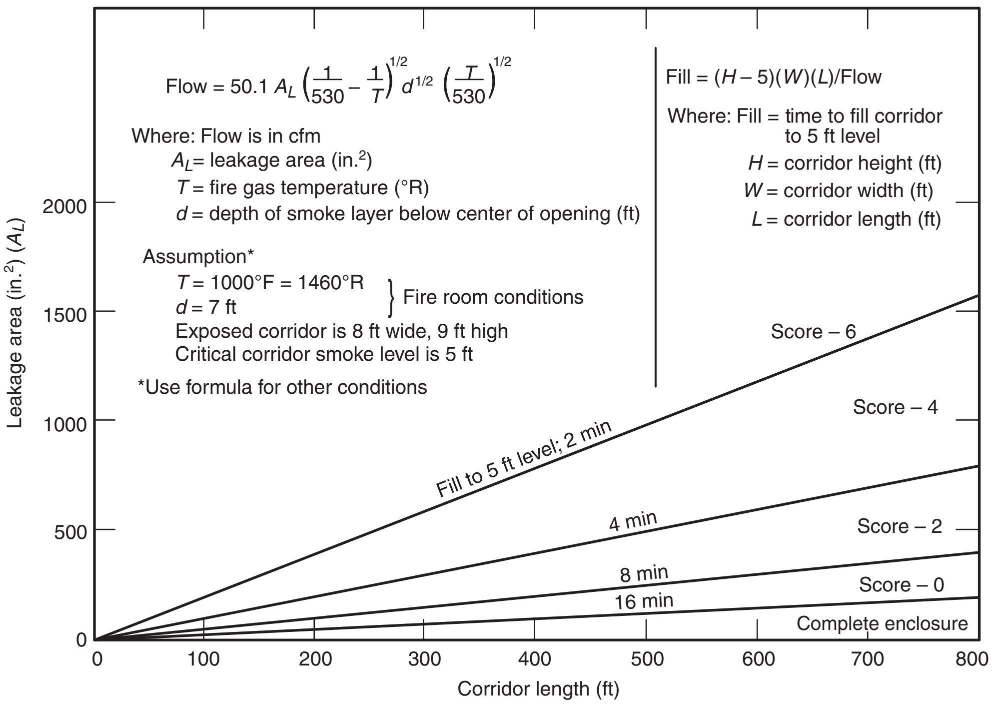
8.5.11.1.2 Complete Separation. The separation, if not judged to be "incomplete" based on the criteria in Table 8.5.11.1.1.2, is considered "complete."

8.5.11.1.3 No Separation. There is "no separation" if the story or the smoke zone is not subdivided (i.e., there is no corridor leading to an exit). *[See 38.3.6.1(1) through 38.3.6.1(3) (NFPA 101).]*

8.5.11.2 For information on credit for door closers, "smoke resistive" versus "≥½ hr" or "1 hr," see Note e to Worksheet 8.6.2.

Table 8.5.11.1.1.2 Incomplete Separation Scores

Safe Time (min)	Score
<2	−6
≥2 but <4	−4
≥4 but <8	−2
≥8 but <16	0
≥16	Complete separation



For SI units, 1 in.^{2} = 6.452 cm^2; 1 ft = 0.3048 m; 5⁄9 (°F – 32) = °C.

FIGURE 8.5.11.1.1.2 Approximate Time to Smoke Impact.

8.5.12 Occupant Emergency Program.

8.5.12.1 The value of this parameter is determined by the number of fire exit drills conducted in the building each year. If no fire exit drills are conducted, the parameter is assessed a value of –2. If drills are conducted once or twice a year, the value is zero (0). If drills are conducted more than twice a year, this parameter is given a value of 1. If the building occupant load is fewer than 500 persons with fewer than 100 persons above or below the street level, this parameter should be given, as a minimum, a value of 1.

8.5.12.2 To qualify for credit, a majority of the building or zone occupants must take part in scenario-oriented fire exit drills. The scenarios should be based on the hazardous conditions that could develop during a fire in the facility.

8.5.12.3 The fire exit drills should be conducted in accordance with the appropriate provisions of NFPA *101*.

8.6 Worksheets for Evaluating Fire Safety in Business Occupancies. The worksheets for evaluating fire safety use a five-step process found in Figure 8.6.

8.6.1 Step 1 — Complete the Cover Sheet Using Worksheet 8.6.1. See Figure 8.6.

8.6.2 Step 2 — Determine Individual Safety Evaluations Using Worksheet 8.6.2. The following steps should be taken:

(1) Select and circle the safety value for each parameter in Worksheet 8.6.2 that best describes the conditions in the facility. Only one value for each of the parameters is to be chosen. If two or more values appear to apply, the one with the lowest point value governs.
(2) Transfer each of the 12 circled safety parameter values from Worksheet 8.6.2 to the available blocks corresponding to each safety parameter in Worksheet 8.6.3. Where the blocks indicate "÷ 2 =," enter one-half the value from Worksheet 8.6.2.
(3) Add each of the three columns, keeping in mind that any negative numbers need to be deducted.
(4) Transfer the resulting values for S_1, S_2, and S_3 to Worksheet 8.6.5.

8.6.3 Step 3 — Determine Mandatory Requirements Using Worksheet 8.6.4. The following steps should be taken:

(1) Circle the mandatory values in Worksheet 8.6.4 for the building being evaluated.
(2) Transfer the circled values from Worksheet 8.6.4 to the boxes marked S_a, S_b, and S_c in Worksheet 8.6.5.

8.6.4 Step 4 — Evaluate Fire Safety Equivalency Using Worksheet 8.6.5. The following steps should be taken:

(1) Perform the subtractions indicated in Worksheet 8.6.5. Enter the differences in the appropriate boxes.
(2) For each row, check "yes" if the value in the answer box is zero (0) or greater. Check "no" if the value in the answer box is negative.

8.6.5 Step 5 – Evaluate Other Considerations Not Previously Addressed, Using Worksheet 8.6.6. The equivalency covered by Worksheets 8.6.2 through 8.6.5 includes the majority of the considerations covered by the *Life Safety Code*. Some considerations are not evaluated by this method and must be considered separately. These additional considerations are covered in Worksheet 8.6.6, Facility Fire Safety Requirements Worksheet. Complete one copy of this separate worksheet for each facility.

8.6.6 Step 6— Determine Equivalency Conclusion. Conclude whether the level of life safety is at least equivalent to that

		Deficient	Not Deficient	Smokeproof Enclosures	
	−6(0)[i]	−2	0	3	5

11. Corridor/Room Separation (compartmentation)	Separation Exists and Level of Protection Is						No Separation, or Single Tenant, or Parameter 4 Value ≥10
		Smoke Resistive[e]		≥½ hr[e]		≥1 hr[e]	
	Incomplete	W/O Door Closer	W/Door Closer	W/O Door Closer	W/Door Closer	W/Door Closer	
	−6 to 0[l]	0	1(2)[f]	1	2(3)[f]	3(4)[f]	3

12. Occupant Emergency Program	Number of Fire Drills Conducted Per Year		
	0	1 to 2	>2
	−2(−3)[m]	0(1)[n]	1(2)[n]

NV – Where these conditions exist, this FSES does not evaluate overall safety. Other analysis techniques shall be permitted to be applied in accordance with the equivalency concept of Section 1.4 of NFPA *101*, *Life Safety Code*.

[a] Use 0 if building is one level.

[b] In any sprinkler-protected spaces, consider flame-spread rating to be 25 or 75 if the interior finish material flame spread does not exceed 75 or 200, respectively.

[c] Increase 200 to 300 if Parameter 4 is 10 or more.

[d] Use 0 if Parameter 11 is −6.

[e] Rate separation as ½ hr (or use actual separation, if greater) if Parameter 4 is 10 or more. Rate separation as "smoke resistive" if Parameter 1 is based on construction Type II(000), III(200), or V(000) and Parameter 4 value < 10.

[f] Use ( ) if separation between rooms also meets criteria.

[g] Use only if all vertical openings have more than 1-hr enclosure and meet the requirements of 7.1.3 and 38.3.1 or 39.3.1 (NFPA *101*).

For SI units, 1 ft = 0.3048 m; 1 ft² = 0.092 m².

[h] Use 50 ft for existing buildings and 20 ft for new construction.

[i] Use ( ) for single exit in accordance with 38.2.4 and 39.2.4 (NFPA *101*).

[j] Use (3) if Parameter 4 value <10.

[k] Use ( ) for building that has:

(a) ≥2 stories above level of exit discharge, or

(b) Occupant load ≥50 (≥100 in existing buildings) above or below level of exit discharge, or

(c) Total occupant load ≥300 (≥1,000 in existing buildings).

[l] See 8.5.11.1.1 for guidance.

[m] Use ( ) in buildings over 150 ft in height with no formal occupant emergency organization program.

[n] Use ( ) in any building, regardless of height, with a formal occupant emergency organization program.

[p] Use ( ) for new high-rise buildings.

(For use with NFPA 101A-2016/NFPA *101*-2015) (p. 2 of 4)

WORKSHEET 8.6.6 FACILITY FIRE SAFETY REQUIREMENTS WORKSHEET

	Considerations	Met	Not Met	Not Applic.
A.	Building utilities conform to the requirements of Section 9.1.			X
B.	The air conditioning, heating, and ventilating systems conform to Section 9.2, except for enclosure of vertical openings, which have been considered in Safety Parameter 3 of Worksheet 8.6.2.			X
C.	Elevator installations are made in accordance with the requirements of Section 9.4.			
D.	Rubbish chutes, incinerators, and laundry chutes are installed in accordance with Section 9.5.			
E.	Portable fire extinguishers are installed and maintained in accordance with the requirements of 38.3.5/39.3.5 and Section 9.9.			X
F.	Standpipes are provided in all new high-rise buildings as required by 38.4.2.			

All references are to NFPA *101*, *Life Safety Code.*

WORKSHEET 8.6.7 CONCLUSIONS

1. ☐ All of the checks in Worksheet 8.6.5 are in the "Yes" column and all applicable considerations in Worksheet 8.6.6 are identified as "Met". The level of fire safety is at least equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for business occupancies.

2. ☐ All of the checks in Worksheet 8.6.5 are in the "Yes" column and all considerations identified in Worksheet 8.6.6 as "Not Met" have been evaluated and mitigated to the satisfaction of the AHJ. The level of fire safety is at least equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for business occupancies.

3. ☐ One or more of the checks in Worksheet 8.6.5 are in the "No" column or any consideration identified in Worksheet 8.6.6 as "Not Met" has NOT been evaluated and mitigated to the satisfaction of the AHJ. The level of fire safety is not shown by this system to be equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for business occupancies.

(For use with NFPA 101A-2016/NFPA *101*-2015) (p. 4 of 4)

FIGURE 8.6 ***Continued***

prescribed by the *Life Safety Code*, using Worksheet 8.6.7, Conclusions. Worksheet 8.6.7 combines the fire safety equivalency evaluation of Worksheet 8.6.5 and the additional considerations of Worksheet 8.6.6.

Chapter 9 Fire Safety Evaluation System for Educational Occupancies

9.1 Introduction.

9.1.1 This chapter is part of an NFPA guide and, therefore, is not mandatory. The term *shall* in this chapter is used to indicate that if the provisions of the chapter are applied, the procedures mandated are to be followed to ensure the effectiveness of the evaluation system.

9.1.2 The Fire Safety Evaluation System (FSES) is a measuring system. It compares the level of safety provided by an arrangement of safeguards that differ from those specified in NFPA *101* to the level of safety provided in a building that conforms exactly with the details of the *Code*.

9.1.3 This Fire Safety Evaluation System is designed and intended to be used for evaluating educational occupancies (as defined in NFPA *101* as applying through the 12th grade). It is not designed or intended to be used for evaluating day care occupancies, assembly occupancies, or other non-educational occupancy uses of educational facilities. Neither is it designed or intended to be used for evaluating educational occupancies located in high-rise buildings.

9.2 Procedure for Determining Equivalency.

9.2.1 Evaluate the factors affecting either every fire zone or the building as a whole using Figure 9.6, Worksheets for Evaluating Fire Safety in Educational Occupancies.

9.2.1.1 Zoning must divide the building into units that consist of one or more complete fire/smoke zones. A fire/smoke zone is a portion of a building that is separated from all other portions of the building by building construction having at least a 1-hour fire resistance rating or smoke barriers having a 30-minute fire resistance rating and conforming to the requirements of Section 8.5 (NFPA *101*), or a combination of both. Any vertical openings (shafts, stairs) involved also must provide 1-hour separation. In facilities completely protected by automatic sprinkler protection, these fire resistance requirements do not apply. The elements separating one zone from another, however, must be of sound, smoke-resisting construction. Doors in zone separations must be either self-closing or equipped with automatic closers operated by smoke detectors.

9.2.1.2 Zones shall be permitted to be either adjacent to each other (e.g., separate wings or building sections) or above each other (e.g., stories or groups of stories).

9.2.1.3 Each zone containing spaces used for an educational occupancy can be evaluated using this system.

9.2.1.4 Each of the 14 safety parameters is to be analyzed, and the safety value for each parameter that best describes the condition in the building is to be identified. Only one value for each of the parameters is to be chosen. If two or more values appear to apply, the one with the lowest point value governs.

9.2.2 Using Worksheet 9.6.6, Facility Fire Safety Requirements, determine the acceptability of the general building systems (i.e., utilities, HVAC, elevator installations, and rubbish chutes, incinerators, and laundry chute installations).

9.2.3 Equivalency is achieved if the building or fire/smoke zone evaluations show equivalency or better in each and every zone and the requirements of Worksheet 9.6.6, Facility Fire Safety Requirements, are met. See Steps 1 through 6 in Section 9.6.

9.3 Glossary for Fire Safety Evaluation Worksheet for Educational Occupancies.

9.3.1 Introduction. This glossary is provided to assist in completing the Worksheet for Evaluating Fire Safety in Educational Occupancies. This glossary provides expanded discussion and definitions for the various items in the worksheets to assist the user where questions of definition or interpretation arise. To the maximum extent possible, the glossary does not repeat the definitions already existing in NFPA *101* but rather references the appropriate paragraphs in NFPA *101*.

9.3.2 Areas of Application.

9.3.2.1 The entire building can be evaluated on a single set of worksheets. The building might, however, be zoned by considering each zone separately or by using any convenient grouping of zones.

9.3.2.1.1 Charges for Safety Parameter 2, "Segregation of Hazards," in Worksheet 9.6.2, Safety Parameters, apply to any hazardous area as described in 9.5.2 in the zone being evaluated and to any hazardous area in zones adjacent to or below the zone being evaluated.

9.3.2.1.2 Where zones are located above each other, the value assigned to Parameter 1, "Construction," in Worksheet 9.6.2, Safety Parameters, in each zone is based on the highest story used for regular human occupancy in that "stack of zones" and the type of construction for that stack of zones.

9.3.2.1.3 The assignment of values for Safety Parameter 5, "Detection, Alarm, and Communication"; Parameter 10, "Exit Access Corridors"; and Parameter 11, "Egress Routes," in Worksheet 9.6.2, Safety Parameters, does not consider conditions in unoccupied spaces in other zones where such are not involved in any egress paths.

9.3.2.1.4 The evaluation of Safety Parameter 11, "Egress Routes," in Worksheet 9.6.2, Safety Parameters, includes those portions of any egress route that serve the zone being evaluated. Any exposures or deficiencies pertaining to any part of the egress route must be taken into account in the evaluation of the zone.

9.3.2.2 Zones that do not involve regular human occupancy are evaluated the same as those with regular human occupancy, with the following variations:

(1) Any such zone shall be permitted to be omitted from the numerical evaluation if both of the following conditions are met:
   (a) The zone is not involved in the egress route from any space with regular human occupancy.
   (b) The zone conforms to NFPA *101* requirements applicable to its use.
(2) Alternatively, such zones shall be permitted to be evaluated using this system, provided any additional egress capabilities and arrangements appropriate to the specific use of the space are provided.

9.4 Maintenance. All protection systems, requirements, arrangements, and procedures shall be maintained in a dependable operating condition and a sufficient state of readiness and shall be used in such a manner that the intended safety function or hazard constraint is not impaired. Otherwise, they shall receive no credit in the evaluation.

9.5 Safety Parameters (Worksheet 9.6.2). The safety parameters are a measure of those building factors that bear upon or contribute to the safety of those persons who might be in the building at the time of a fire. The safety parameters in Worksheet 9.6.2 are described in 9.5.1 through 9.5.14.

9.5.1 Construction. Construction types are classified in accordance with the definitions of NFPA 220. Where the facility includes additions or connected structures of different construction, the rating and classification of the structure is based on one of the following:

(1) Separate buildings where the separation between the portions of the building is a fire barrier having at least a 2-hour fire resistance rating and any opening protectives have at least a 1½-hour fire protection rating
(2) The lower safety parameter point score involved where such a separation does not exist

9.5.2 Segregation of Hazards. The assignment of charges for unsegregated hazardous contents areas is a four-step process.

9.5.2.1 Step 1 — Identify Hazardous Contents Areas. A hazardous area is any space or compartment in which a hazardous activity or storage of flammable or readily combustible products exists that possesses the potential for producing a fully involved fire. Examples of these types of areas in typical educational occupancies include the following:

(1) Laundries
(2) Chemistry storage rooms
(3) Maintenance (such as woodworking and painting areas)
(4) Janitor closets
(5) Boiler rooms and furnace rooms
(6) Rooms used for the storage or processing of combustible supplies
(7) Rooms used for the storage or processing of hazardous materials, flammable liquids, or combustible liquids

9.5.2.2 Step 2 — Determine the Level of Hazard. There are two levels of hazard: structurally endangering and not structurally endangering.

9.5.2.2.1 Structurally Endangering. A hazardous area with a potential fire severity that might exceed the tested resistance of the enclosure and defeat the basic structural integrity of the building framing as defined in Safety Parameter 1, "Construction," of Worksheet 9.6.2. In educational occupancies, shops and industrial technology areas involving the use of open flames, welding operations, and limited quantities of flammable liquids should be considered structurally endangering. Other areas not having these types of uses should be considered not structurally endangering.

9.5.2.2.2 Not Structurally Endangering. A hazardous area with sufficient fire potential to build to full involvement (flashover) and present a danger of propagating through openings or wall partitions but not possessing sufficient total potential to endanger the structural framing or floor decking as defined in Safety Parameter 1 of Worksheet 9.6.2.

9.5.2.3 Step 3 — Determine the Fire Protection Provided.

9.5.2.3.1 The parameter value for hazardous areas is based on the presence or absence of the fire protection necessary to control or confine the hazard. Two different types of fire protection are considered. The first consists of automatic sprinklers or other appropriate extinguishing systems covering the entire hazard. The credit for sprinklers shall not be given unless the hazardous area is separated from the rest of human occupancy or the egress route by reasonably smoke-resistant partitions and doors (other than sprinklered janitor closets with louvered doors in accordance with 14.3.2.1 or 15.3.2.1 of NFPA *101*). The second is a complete fire enclosure having a sufficient fire resistance rating to contain the potential fire severity of the hazardous area. This includes the following:

(1) The separation of the hazardous area from any structural framing members
(2) Partitions separating the hazardous area from all other spaces
(3) Fire protection–rated doors sufficient to exceed the potential of the fire load involved

9.5.2.3.2 Any hazardous space that has any of these protection systems is classified as having single protection.

9.5.2.4 Step 4 — Determine Degree of Deficiency and Assign Parameter Values.

9.5.2.4.1 The parameter value ultimately is determined by the degree of the deficiency of the hazardous contents area based on the level of protection needed. Table 9.5.2.4.1 provides a matrix to be used to determine the degree of deficiency to be assessed.

9.5.2.4.2 In some situations, more than one hazardous area with the same or differing levels of deficiency exists. The overall charge is based on the single most serious deficiency for the hazardous area.

9.5.3 Vertical Openings. These values apply to vertical openings and penetrations including exit stairways, ramps, and any

Table 9.5.2.4.1 Segregation of Hazards — Degree of Deficiency

	No protection	Sprinkler protection	Fire resistance–rated enclosure*	Sprinklered and fire resistance–rated enclosure*
Not structurally endangering	Single deficiency	No deficiency		
Structurally endangering	Double deficiency	Single deficiency	Single deficiency	No deficiency

*Complete enclosure having sufficient fire resistance to contain the potential of the hazardous contents area.

other vertical exits, pipe shafts, ventilation shafts, duct penetrations, and laundry and incinerator chutes. The charge for vertical openings is based on the fire resistance of the enclosure, if provided.

9.5.3.1 A vertical opening or penetration is classified as open if it has any of the following characteristics:

(1) Unenclosed
(2) Unenclosed but is the only vertical opening and is in accordance with the convenience opening provisions of 8.6.9.1 of NFPA *101*, in which case the parameter value of 9.5.3.1(2) is to be assigned
(3) Enclosed but has doorways (or similar portals) that are without doors
(4) Enclosed but has unprotected openings other than doorways
(5) Enclosed with cloth, paper, or similar materials without any sustained fire-stopping capabilities

9.5.3.2 The credit for vertical opening protection varies depending on the number of stories connected by the vertical opening and the degree of enclosure.

9.5.4 Sprinklers.

9.5.4.1 Where an automatic sprinkler is installed for either total or partial building coverage, the system shall be in accordance with Section 9.7 (NFPA *101*) for the sprinklered areas.

9.5.4.2 To receive credit for protection, the sprinkler system must be equipped with an automatic alarm-initiating device that activates the building's fire alarm system or otherwise sounds an alarm sufficiently audible to be heard in all occupied areas.

9.5.4.3 To receive credit for "complete building" sprinkler protection, the entire building must be provided with sprinkler coverage and must cover all zones of the building.

9.5.4.4 To receive credit for "partial – occupied areas" sprinkler protection, sprinklers must be provided throughout all areas subject to occupancy and all hazardous contents areas.

9.5.5 Detection, Alarm, and Communication. Fire alarm systems are defined in 9.5.5.1 through 9.5.5.4.

9.5.5.1 None. There is no fire alarm system, or the system is incomplete and does not meet the requirements for a higher-scored category.

9.5.5.2 Manual System Only. There is a manual fire alarm system that provides automatic occupant notification and meets the requirements of Section 9.6 (NFPA *101*). An alternative protection system in accordance with 14.3.4.2.3 or 15.3.4.2.3 (NFPA *101*) is to be considered an alarm system with manual initiation.

9.5.5.3 Manual with Fire Detection in Hazardous Areas. There is a manual fire alarm system that provides automatic occupant notification, where additional initiation occurs via automatic fire detection in hazardous areas such as boiler rooms, shops, laboratories, kitchens, laundry rooms, and storage rooms, and such system meets the requirements of Section 9.6 (NFPA *101*).

9.5.5.4 Manual with Smoke Detection. There is a manual fire alarm system that provides automatic occupant notification, where additional initiation occurs via automatic smoke detection throughout the building, and such system meets the requirements of Section 9.6 (NFPA *101*).

9.5.6 Emergency Forces Notification. Emergency forces notification means are defined in 9.5.6.1 through 9.5.6.3.

9.5.6.1 None. There is no emergency forces notification, or the system is incomplete and does not meet the requirements for a higher-scored category.

9.5.6.2 Administrative. Administrative emergency forces notification is a system in accordance with 15.3.4.3.2.1 (NFPA *101*).

9.5.6.3 Automatic. Automatic emergency forces notification is a system in accordance with 9.6.4 (NFPA *101*).

9.5.7 Interior Finish in Exits.

9.5.7.1 Classification of interior finish is based on the flame-spread index and smoke developed index of the interior wall and ceiling finish materials tested in accordance with ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*. The requirements apply to interior wall and ceiling finish materials as described in Section 10.2 (NFPA *101*).

9.5.7.2 No consideration is included in the safety parameter value for any finish with a flame-spread index of more than 200 as measured by ASTM E84, *Standard Test Method for Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*. Thus, this FSES should not be used where such conditions exist. Some materials, including foam plastics, high-density polyethylene, and polypropylene, are not permitted to be tested in accordance with ASTM E84 and must be tested in accordance with NFPA 286 and must meet the acceptance criteria shown in 10.2 (NFPA *101*). Some materials, including asphalt-impregnated paper, are capable of inducing extreme rates of fire growth and rapid flashover. In any case involving these materials, the resultant hazard is considered beyond the capacity of this evaluation system and requires an individual fire hazard assessment.

9.5.7.3 Interior wall and ceiling finish materials tested in accordance with NFPA 265 or NFPA 286 as permitted by Section 10.2 (NFPA *101*), and meeting the criteria established in Section 10.2 (NFPA *101*) for those test standards, shall be scored as Class A interior finish materials (flame spread ≤25).

9.5.7.4 Any interior finish having a flame-spread index of 75 or less that is protected by automatic sprinklers is evaluated as having a flame-spread index not exceeding 25. Any interior finish having a flame-spread index of more than 75 but not more than 200 that is protected by automatic sprinklers is evaluated as having a flame-spread index not exceeding 75.

9.5.8 Interior Finish in Corridors and Lobbies. See 9.5.7.

9.5.9 Interior Finish in Rooms. See 9.5.7.

9.5.10 Exit Access Corridor.

9.5.10.1 The charge for dead-end access is made where any corridor affords access in only one direction to a required exit.

9.5.10.2 If a dead-end corridor distance exceeds 75 ft (23 m), a separate analysis must be made to evaluate the potential of flashover of any spaces that could block egress from the dead-end corridor and to determine the potential rate of smoke-filling of the egress system involved. If the safe time is shorter than the expected egress time, the evaluation should be discontinued unless a corrective action is specified.

9.5.10.3 Any system with common path of travel in excess of that permitted by NFPA *101* should be considered deficient under Safety Parameter 11, "Egress Routes."

9.5.11 Egress Routes.

9.5.11.1 Egress routes are the paths of travel from any point within a room to the public way using any types and arrangements described in Chapters 14 and 15 (NFPA *101*).

9.5.11.2 Egress routes are defined in 9.5.11.2.1 through 9.5.11.2.5.

9.5.11.2.1 Single Egress Route. A single route exists where occupants on any story do not have either a direct exit to a public way or multiple egress routes as defined in 9.5.11.2.2.

9.5.11.2.2 Multiple Egress Routes. Multiple routes exist where the occupants on a story have a choice of two separate means of egress routes to a public way using the permitted types in Chapters 14 and 15 (NFPA *101*).

9.5.11.2.3 Deficient — Multiple Egress Routes. An egress route is deficient if it fails to meet any of applicable criteria of NFPA *101* including capacity. Any system with common path of travel in excess of that permitted by Chapters 14 and 15 (NFPA *101*) should be considered deficient under Parameter 11, "Egress Routes." An egress route is deficient if a room or space larger than 1000 ft^2 (92.9 m^2) or with an occupant load of more than 50 persons does not have a minimum of two exit access doors providing access to separate exits.

9.5.11.2.4 Smokeproof Enclosure. Credit for a smokeproof enclosure shall be permitted to be given for a stairway designed and tested in accordance with the requirements of 7.2.3 (NFPA *101*) for a smokeproof enclosure. To receive credit for a smokeproof enclosure, all exit stairs credited in Safety Parameter 10, "Exit Access Corridor," and Safety Parameter 11, "Egress Routes," shall meet the smokeproof enclosure requirements.

9.5.11.2.5 Direct Exit. To be credited for direct exits, each room shall have within that unit a door that opens to the exterior at grade level or onto an exterior balcony with direct access to an exterior exit. Where such openings are directly onto grade in a location where any person egressing can move directly away from the building without further exposure, the credit for direct exit shall be given even if there are no other egress routes from the space.

9.5.12 Corridor/Room Separation. The values assigned in Safety Parameter 12, "Corridor/Room Separation," are based on the quality of separation between the room and the corridor. For purposes of this evaluation, corridor separation in educational occupancy buildings is considered as complete if it meets the requirements of 14.3.6 or 15.3.6 (NFPA *101*). For areas within educational occupancies that use an "open-plan" concept where all of the classrooms egress through an intervening space (such as a media or activity center), a separate evaluation is recommended that calculates fuel loading and available safe egress time.

9.5.12.1 Corridor/room separation is defined in 9.5.12.1.1 through 9.5.12.1.4.

9.5.12.1.1 No Separation Exists or Multiple Penetrations. The separation is judged to be nonexistent if there is no corridor leading to an exit, there are no barriers against smoke or fire spread, there are no doors between corridors and adjacent rooms, or there are multiple penetrations. Examples of penetrations include transfer grilles for air movement, transoms, and non-fire-rated glass.

9.5.12.1.2 Incomplete. The separation is judged as "incomplete" if the wall to the corridor has some unprotected openings (for example, louvers, gaps, or transfer grilles) between the floor and ceiling but these openings are minor in relation to the area of the room or are located low in walls or doors. If openings exist above the ceiling level, the separation is considered complete if the ceiling in the room is a completed membrane. In this case, the separation rating is based on the level of resistance involved in the wall/ceiling system.

9.5.12.1.3 Solid Core Doors. This parameter should be used if the corridor/room doors are solid core wood or metal doors at least 1¾ in. (44 mm) thick.

9.5.12.1.4 Doors with ≥20-Minute Fire Protection Rating. Use this parameter if doors and frames are fire protection–rated for 20 minutes or greater protection and are self-closing or automatic-closing.

9.5.13 Smoke Control.

9.5.13.1 The active smoke control value should be used when an engineered smoke control system complying with NFPA 92 is installed and the building is protected throughout by an approved, supervised automatic sprinkler system in accordance with Section 9.7 (NFPA *101*).

9.5.13.2 The passive smoke control with auto-closing doors value should be used when the building is subdivided into compartments by smoke partitions having a 1-hour fire resistance rating complying with Section 8.4 (NFPA *101*), and all doors located within the smoke partition are designed to close automatically upon the activation of the fire alarm system or the fire sprinkler system per *NFPA 72*.

9.5.13.3 The passive smoke control value should be used when the building is subdivided into compartments by smoke partitions having a 1-hour fire resistance rating complying with Section 8.4 (NFPA *101*), but not meeting the provisions of 9.5.13.2.

9.5.14 Occupant Emergency Program.

9.5.14.1 The value of this parameter is determined by the number of emergency egress and relocation drills conducted in the building each year.

9.5.14.2 To receive a parameter value other than -6, the building or zone occupants are required to take part in scenario-oriented emergency egress and relocation drills conducted in accordance with the appropriate provisions of NFPA *101*. The scenarios should be based on the hazardous conditions that could develop during a fire in the facility. The scenarios should also include planning and provisions for the evacuation or relocation of occupants with disabilities.

9.6 Worksheets for Evaluating Fire Safety in Educational Occupancies. The worksheets for evaluating fire safety in educational occupancies use a six-step process found in Figure 9.6.

9.6.1 Step 1 — Complete the Cover Sheet Using Worksheet 9.6.1. See Figure 9.6.

9.6.2 Step 2 — Determine Individual Safety Evaluations Using Worksheet 9.6.2. The following steps should be taken:

WORKSHEET 9.6.1 COVER SHEET

Fire Safety Evaluation Worksheet for Educational Occupancies

Facility Identification ______________________________

Evaluator ______________________ Date ______________________

Notes:

WORKSHEET 9.6.2 SAFETY PARAMETERS

Safety Parameters	Parameter Values							
1. Construction	Combustible					Noncombustible		
NFPA 220 Building Construction Types/ Stories in Height	Type V (000)	Type V (111)	Type IV (2HH)	Type III (200)	Type III (211)	Type II (000)	Type II (111)	Type I(442), Type I(332), Type II(222)
1 Story	1	2	2	1	2	1	2	2
2 Stories	0	1	1	0	1	0	1	2
3 Stories	–4	0	0	–4	0	–4	0	2
≥4 Stories but not High Rise	–8	–1	–1	–8	–1	–8	–1	2

Safety Parameters	Exposed to Exit System		Segregated from Exit Routes		None or No Deficiencies
2. Segregation of Hazards	Double Def.	Single Def.	Double Def.	Single Def.	
	–7	–4	–4	0	0

Safety Parameters	Open (or incomplete enclosure)			No Opening	Enclosed		
3. Vertical Openings	Connects 4 or More Stories	Connects 3 Stories	Connects 2 Stories	Single Story Building W/O Basement	Smoke Resistant or <30 min	≥30 min to <1 hr	≥1 hr
	–10	–6	–2(2)[a]	2(1)[b]	1	1	2(1)[c,d]

Safety Parameters		Partial		Complete Building	
4. Sprinklers[e]	None	Hazardous Contents Areas Only	Occupied Areas but not Throughout Unoccupied Areas	Standard Response Sprinklers	Quick Response Sprinklers
	0(–2)[f,g]	1(–1)[f,g]	6(0)[g]	10	12

Safety Parameters				
5. Detection, Alarm, and Communication[h]	None	Alarm System with Manual Initiation and Automatic Occupant Notification	Alarm System with Manual Initiation, Fire Detection in Hazardous Contents Areas, and Automatic Occupant Notification	Alarm System with Manual Initiation, Complete Smoke Detection, and Automatic Occupant Notification
	–6	0(1)[n,o]	2(3)[n,o]	6

(Worksheet 9.6.2 continues.)

(For use with NFPA 101A-2016/NFPA *101*-2015) (p. 1 of 4)

FIGURE 9.6 Worksheets for Evaluating Fire Safety in Educational Occupancies.

Worksheet 9.6.2 *Continued*

6. Emergency Forces Notification	None	Administrative	Automatic
	–1	0(–1)[i]	1(–1)[i]

7. Interior Finish in Exits (Flame-Spread Ratings)	>75 to ≤200	>25 to ≤75	≤25
	–2	–1	0

8. Interior Finish in Corridors and Lobbies (Flame-Spread Ratings)	>75 to ≤200	>25 to ≤75	≤25
	–3	–2	0

9. Interior Finish in Rooms (Flame-Spread Ratings)	>75 to ≤200	>25 to ≤75	≤25
	–2	–1	0

10. Exit Access Corridors	Max. Dead End Length		No Dead Ends >20 ft (>50 ft if Parameter 4 is ≥10) and Travel Is			
	>50 ft to ≤75 ft	>20 ft to ≤50 ft and Parameter 4 is <10	>200 ft	>150 ft to ≤200 ft	>50 ft to ≤150 ft	≤50 ft
	–2	–1	–2	–1	0	2

11. Egress Routes	Single Route	Multiple Routes			Direct Exit
		Deficient	Not Deficient	Smokeproof Enclosures	
	NV(–6)[j]	–2	0	1	5

12. Corridor/Room Separation	No Separation Exists or Multiple Penetrations	Separation Exists and Level of Protection is					
		Incomplete	Smoke Partitions		Fire-Rated Walls (≥½ hr Existing, ≥1 hr New)		
			Smoke-Resistant Door W/O Closer	Smoke-Resistant Door W/Closer	Smoke-Resistant Door W/Closer	Solid-Core Doors (no nonrated glazing) W/Closer	Doors W/≥20-min FPR
	–3	–2	–1(0)[l]	0(0)[m]	0(0)[m]	1	2

13. Smoke Control	None	Passive	Passive with Auto Closing Doors	Active
	–2	0(0)[k]	1	2

14. Occupant Emergency Program	Number of Emergency Egress and Relocation Drills Conducted		
	None	≥2 during first 2 months, plus ≥2 others spread out during remainder of school year	≥2 during first month, plus ≥1 per month during remainder of school year
	–6	–3	0

NV – Where a single egress route exists for other than a 1-story building, this FSES does not evaluate overall safety. Other analysis techniques might be applied in accordance with the equivalency concept of Section 1.4 of NFPA *101, Life Safety Code.*

[a] Use (2) if only vertical opening is in accordance with 8.6.9.1 (NFPA *101*).

[b] Use (1) if educational occupancy is existing.

[c] Use (1) if vertical opening enclosure is existing.

[d] Use (1) if building construction is Type II(000), Type III(200) or Type V(000).

[e] For sprinkler parameter values >0, sprinkler system must be electrically supervised.

[f] Use ( ) in existing educational occupancy if student occupied level below LED is not sprinklered.

[g] Use ( ) in new educational occupancy if level below LED is not sprinklered.

[h] If alternative protection system is provided in accordance with 14.3.4.2.3 or 15.3.4.2.3 (NFPA *101*), see 9.5.5.2.

[i] Use (-1) if Parameter 5 value is -6.

[j] Use (-6) for 1-story buildings only; for other than 1-story buildings the NV note applies.

[k] Use (0) if no smoke control but aggregate floor area having a common atmosphere <30,000 ft^2 and building <300 ft length and <300 ft width.

[l] Use (0) if room is normally occupied classroom and Parameter 4 is ≥10.

[m] Use (0) where door is without closer if room is normally occupied classroom and Parameter 4 is ≥10.

[n] Use ( ) in new educational occupancy if alarm system is provided with voice/alarm communication.

[o] Use ( ) in new educational occupancy if alarm system is in a building with occupant load ≥100.

(For use with NFPA 101A-2016/NFPA *101*-2015) (p. 2 of 4)

WORKSHEET 9.6.6 FACILITY FIRE SAFETY REQUIREMENTS

	Considerations	Met	Not Met	Not Applic.
A.	Building utilities conform to the requirements of Section 9.1 (NFPA *101*).			X
B.	The air conditioning, heating, and ventilating systems conform to Section 9.2 (NFPA *101*), except for enclosure of vertical openings, which have been considered in Safety Parameter 3 of Table 9.6.2.			X
C.	Elevator installations are made in accordance with the requirements of Section 9.4 (NFPA *101*).			
D.	Rubbish chutes, incinerators, and laundry chutes are installed in accordance with Section 9.5 (NFPA *101*).			
E.	Emergency lighting is provided in accordance with the requirements of 14.2.9 and 15.2.9 (NFPA *101*).			
F.	Exit signs are provided in accordance with the requirements of 14.2.10 and 15.2.10 (NFPA *101*).			
G.	Kindergarten, first and second grade student occupancy within the building conforms to the requirements of 14.2.1.2 through 14.2.1.4 and 15.2.1.2 through 15.2.1.4 (NFPA *101*).			X
H.	Artwork on walls and ceilings conforms to the requirements of 14.7.4.3 and 15.7.4.3 (NFPA *101*).			X
I.	Carbon monoxide detection/alarm is provided in accordance with 14.3.4.4 (NFPA *101*).			

WORKSHEET 9.6.7 CONCLUSIONS

1. ☐ All of the checks in Worksheet 9.6.5 are in the "Yes" column and all applicable considerations in Worksheet 9.6.6 are identified as "Met". The level of fire safety is at least equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for educational occupancies.

2. ☐ All of the checks in Worksheet 9.6.5 are in the "Yes" column and all considerations identified in Worksheet 9.6.6 as "Not Met" have been evaluated and mitigated to the satisfaction of the AHJ. The level of fire safety is at least equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for educational occupancies.

3. ☐ One or more of the checks in Worksheet 9.6.5 are in the "No" column or any consideration identified in Worksheet 9.6.6 as "Not Met" has NOT been evaluated and mitigated to the satisfaction of the AHJ. The level of fire safety is not shown by this system to be equivalent to that prescribed by NFPA *101*, *Life Safety Code*, for educational occupancies.

(For use with NFPA 101A-2016/NFPA *101*-2015) (p. 4 of 4)

FIGURE 9.6 ***Continued***

(1) Select and circle the safety value for each parameter in Worksheet 9.6.2, Safety Parameters, that best describes the conditions in the facility. Only one value for each of the parameters is to be chosen. If two or more values appear to apply, the one with the lowest point value governs.
(2) Transfer each of the 14 circled safety parameter values from Worksheet 9.6.2 to the available blocks corresponding to each safety parameter in Worksheet 9.6.3, Individual Safety Evaluation. Where the blocks indicate "÷2," enter one-half the value from Worksheet 9.6.2.
(3) Add each of the three columns, keeping in mind that any negative numbers need to be deducted.
(4) Transfer the resulting values for S_1, S_2, and S_3 to Worksheet 9.6.5, Equivalency Evaluation.

9.6.3 Step 3 — Determine Mandatory Requirements Using Worksheet 9.6.4A or 9.6.4B. The following steps should be taken:

(1) Circle the mandatory values in Worksheet 9.6.4A or 9.6.4B, Mandatory Safety Requirements, as appropriate for the building being evaluated.
(2) Transfer the circled values from Worksheet 9.6.4A or 9.6.4B to the boxes marked S_a, S_b, and S_c in Worksheet 9.6.5, Equivalency Evaluation.

9.6.4 Step 4 — Evaluate Fire Safety Equivalency Using Worksheet 9.6.5. The following steps should be taken:

(1) Perform the subtractions indicated in Worksheet 9.6.5. Enter the differences in the appropriate boxes.
(2) For each row, check "yes" if the value in the answer box is zero (0) or greater. Check "no" if the value in the answer box is negative.

9.6.5 Step 5 — Evaluate Other Considerations Not Previously Addressed, Using Worksheet 9.6.6. The equivalency covered by Worksheets 9.6.2 through 9.6.5 includes the majority of considerations covered by the *Life Safety Code*. Some considerations are not evaluated by this method and must be considered separately. These additional considerations are covered in Worksheet 9.6.6, Facility Fire Safety Requirements. Complete one copy of this separate worksheet for each facility.

9.6.6 Step 6 — Determine Equivalency Conclusion. Conclude whether the level of life safety is at least equivalent to that prescribed by the *Life Safety Code*, using Worksheet 9.6.7, Conclusions. Worksheet 9.6.7 combines the zone fire safety equivalency evaluation of Worksheet 9.6.5 and the additional considerations of Worksheet 9.6.6.

Annex A Explanatory Material

Annex A is not a part of the recommendations of this NFPA document but is included for informational purposes only. This annex contains explanatory material, numbered to correspond with the applicable text paragraphs.

A.1.3.1 The mandatory values presented in worksheets in the various FSES chapters are calibrated to measure safety against the provisions of the most current edition of NFPA *101* which, in the case of this 2016 edition of NFPA 101A, is the 2015 edition. The spreadsheets used to calculate the mandatory values serve as a record of the safety parameters and associated point values determined by the technical committee as the baseline required by the *Code*. The spreadsheets are maintained in the permanent committee files at NFPA headquarters, serve as the historical record, and are consulted when each new edition of NFPA *101* is published to determine what mandatory values need further calibration.

A.3.2.1 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

A.3.2.2 Authority Having Jurisdiction (AHJ). The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A.3.2.5 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

Standard for

Grandstands, Folding and Telescopic Seating, Tents, and Membrane Structures

2016 Edition

This edition of NFPA 102, *Standard for Grandstands, Folding and Telescopic Seating, Tents, and Membrane Structures*, was prepared by the Technical Committee on Assembly Occupancies and Membrane Structures and released by the Correlating Committee on Safety to Life. It was issued by the Standards Council on January 28, 2015, with an effective date of February 17, 2015, and supersedes all previous editions.

This edition of NFPA 102 was approved as an American National Standard on February 17, 2015.

Origin and Development of NFPA 102

This standard is the result of a committee project inaugurated shortly after the circus fire in Hartford, CT, on July 6, 1944, in which 168 lives were lost.

A committee was organized under the joint sponsorship of the Building Officials Conference of America and the National Fire Protection Association under the procedure of the American Standards Association. As a result of extensive deliberation during the winter of 1944–1945, this committee prepared a draft of a proposed standard, which was submitted at the annual meeting of the National Fire Protection Association in June, 1945. This was then printed and sent to all of the members of the Association, to a representative group of leaders in the outdoor amusement industry, and to all others who filed requests for copies. As a result, numerous constructive suggestions were received, all duly considered by the committee in several meetings, and the 1946 standard was completed by the committee. It was then adopted by the sponsoring organizations, the National Fire Protection Association, and the Building Officials Conference of America, and approved by the American Standards Association as an American Standard on May 22, 1946.

As a result of circulation and use of the 1946 standard, various proposals were made for revision in the interest of clarification. These were considered by the committee and revisions recommended by the committee and circulated to all concerned for comment, further amended, and adopted by the National Fire Protection Association and the Building Officials Conference of America in 1948; the American Standards Association approved the 1948 edition as an American Standard on January 5, 1949.

In 1949 the committee recommended further changes to include the essential features of an earlier standard on grandstands, Z20.1, which covered certain types of grandstands not covered in the 1946–1948 standard, Z20.2, thus making the continuance of the earlier separate standard unnecessary. The 1949 revision, Z20.3, also made the standard applicable to foldable grandstands in buildings that had not been previously covered. After the usual circulation for comment, the revisions were adopted in 1949 by the sponsors, and the revised text was approved by the American Standards Association as an American Standard on April 5, 1950.

Revised editions of the standard have been prepared by the committee and adopted by the sponsors in 1957, 1966, and 1967. The 1972 edition was a reconfirmation of the 1967 edition.

The 1978 edition was prepared by the Committee on Tents, Grandstands, and Air- Supported Structures and represented a complete revision of the 1972 edition, complete with a new title, *Standard for Assembly Seating, Tents, and Air-Supported Structures*. The means of egress section was coordinated with the provisions of NFPA *101, Life Safety Code*.

The 1986 edition further coordinated with the *Life Safety Code*. It was prepared by the Technical Committee on Safety to Life through its Subcommittee on Tents and Membrane Structures. Its scope was extended beyond assembly occupancies to include tents and membrane structures used for any occupancy.

NFPA and National Fire Protection Association are registered trademarks of the National Fire Protection Association, Quincy, Massachusetts 02169.

The 1992 and 1995 editions deleted all means of egress provisions that were adequately covered by NFPA *101, Life Safety Code*, so as to avoid redundancy and inconsistencies between the two documents. The 1995 edition was retitled *Standard for Grandstands, Folding and Telescopic Seating, Tents, and Membrane Structures* to reflect more accurately the scope and contents of the document.

The 2006 edition was the first to be wholly comprised of requirements extracted from NFPA *101, Life Safety Code*, and NFPA 5000, *Building Construction and Safety Code*.

The 2011 edition continued the extract policy.

For future revision cycles, users were advised to submit public proposals on extracted text to the source documents (that is, NFPA *101* and NFPA 5000) and not to NFPA 102

The 2016 edition continues the extract policy.

Correlating Committee on Safety to Life

William E. Koffel, *Chair*
Koffel Associates, Inc., MD [SE]

Ron Coté, *Administrative Secretary*
National Fire Protection Association, MA

Wayne D. Holmes, HSB Professional Loss Control, NC [I]
Howard Hopper, UL LLC, CA [RT]
Stephen Hrustich, Gwinnett County Fire & Emergency Services, GA [U]
Rep. International Association of Fire Chiefs
Jeffrey M. Hugo, National Fire Sprinkler Association, Inc., MI [M]
J. Edmund Kalie, Jr., Prince George's County Government, MD [E]
Isaac I. Papier, Honeywell, Inc., IL [M]
Rep. National Electrical Manufacturers Association
Jake Pauls, Jake Pauls Consulting Services, Canada [C]
Rep. American Public Health Association
James R. Quiter, Arup, CA [SE]
Ronald C. Reynolds, Virginia State Fire Marshal's Office, VA [E]
Rep. International Fire Marshals Association
Eric R. Rosenbaum, Hughes Associates/RJA Group, MD [U]
Rep. American Health Care Association

Alternates

Sharon S. Gilyeat, Koffel Associates, Inc., MD [SE]
(Alt. to W. E. Koffel)
Stanley C. Harbuck, School of Building Inspection, UT [C]
(Alt. to J. Pauls)
Robert J. James, UL LLC, FL [RT]
(Alt. to H. Hopper)
Dale L. Lyman, Greeley Fire Department, CO [U]
(Alt. to S. Hrustich)
Rodger Reiswig, Tyco/SimplexGrinnell, FL [M]
(Alt. to I. I. Papier)
Robert Upson, National Fire Sprinkler Association, NY [M]
(Alt. to J. M. Hugo)

Nonvoting

Chad E. Beebe, ASHE - AHA, WA [E]
Rep. TC on Board & Care Facilities
Wayne G. Carson, Carson Associates, Inc., VA [SE]
Rep. TC on Fundamentals
Shane M. Clary, Bay Alarm Company, CA [IM]
Rep. Signaling Systems Correlating Committee
David S. Collins, The Preview Group, Inc., OH [SE]
Rep. TC on Means of Egress
John F. Devlin, Aon Fire Protection Engineering Corporation, MD [I]
Rep. TC on Fire Protection Features
Victor L. Dubrowski, Code Consultants, Inc., MO [SE]
Rep. TC on Educational & Day-Care Occupancies
Randy Gaw, Kanata, ON, Canada [SE]
Rep. TC on Detention & Correctional Occupancies
Joseph M. Jardin, Fire Department City of New York, NY [C]
Rep. TC on Building Service & Fire Protection Equipment
David P. Klein, U.S. Department of Veterans Affairs, DC [U]
Rep. TC on Health Care Occupancies
James K. Lathrop, Koffel Associates, Inc., CT [SE]
Rep. TC on Residential Occupancies
Wayne D. Moore, Hughes Associates/RJA Group, RI [SE]
Rep. Signaling Systems Correlating Committee
Amy J. Murdock, Code Consultants, Inc., MO [SE]
Rep. TC on Mercantile & Business Occupancies
Henry Paszczuk, Connecticut Department of Public Safety, CT [E]
Rep. TC on Interior Finish & Contents
Jeffrey S. Tubbs, Arup, MA [SE]
Rep. TC on Assembly Occupancies
Joseph H. Versteeg, Versteeg Associates, CT [E]
Rep. TC on Alternative Approaches to Life Safety
Carl D. Wren, Austin Fire Department, TX [E]
Rep. TC on Industrial, Storage, & Miscellaneous Occupancies

Ron Coté, NFPA Staff Liaison

This list represents the membership at the time the Committee was balloted on the final text of this edition. Since that time, changes in the membership may have occurred. A key to classifications is found at the back of the document.

NOTE: Membership on a committee shall not in and of itself constitute an endorsement of the Association or any document developed by the committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on the protection of human life from fire and other circumstances capable of producing similar consequences and for the non-emergency and emergency movement of people.

Technical Committee on Assembly Occupancies

This list represents the membership at the time the Committee was balloted on the final text of this edition. Since that time, changes in the membership may have occurred. A key to classifications is found at the back of the document.

NOTE: Membership on a committee shall not in and of itself constitute an endorsement of the Association or any document developed by the committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on protection of human life and property from fire and other circumstances capable of producing similar consequences, and on the non-emergency and emergency movement of people in assembly occupancies, tents, and membrane structures.

NFPA 102

Standard for

Grandstands, Folding and Telescopic Seating, Tents, and Membrane Structures

2016 Edition

IMPORTANT NOTE: This NFPA document is made available for use subject to important notices and legal disclaimers. These notices and disclaimers appear in all publications containing this document and may be found under the heading "Important Notices and Disclaimers Concerning NFPA Standards." They can also be obtained on request from NFPA or viewed at www.nfpa.org/disclaimers.

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates that explanatory material on the paragraph can be found in Annex A.

A reference in brackets [ ] following a section or paragraph indicates material that has been extracted from another NFPA document. As an aid to the user, the complete title and edition of the source documents for extracts in mandatory sections of the document are given in Chapter 2 and those for extracts in informational sections are given in Annex B. Extracted text may be edited for consistency and style and may include the revision of internal paragraph references and other references as appropriate. Requests for interpretations or revisions of extracted text shall be sent to the technical committee responsible for the source document.

Information on referenced publications can be found in Chapter 2 and Annex B.

Chapter 1 Administration

1.1 Scope. This standard addresses the following:

(1) The construction, location, protection, and maintenance of grandstands and bleachers, folding and telescopic seating, tents, and membrane structures
(2) Seating facilities located in the open air or within enclosed or semi-enclosed structures such as tents, membrane structures, and stadium complexes.

1.2 Purpose. The purpose of this standard is to provide minimum requirements for life safety in relation to fire, storm, collapse, and crowd behavior in tents, membrane structures, and assembly seating as covered in Section 1.1.

1.3 Application. The requirements of this standard shall apply to the following:

(1) New facilities
(2) Existing facilities where specifically noted

1.4 Equivalency.

1.4.1 General. Nothing in this standard shall prohibit methods of construction, materials, and designs not specifically prescribed in this standard where equivalent alternatives are approved by the authority having jurisdiction (AHJ).

1.4.2 Approval of Alternatives. Alternative systems, methods, or devices approved as equivalent by the authority having jurisdiction shall be recognized as being in compliance with this standard.

1.4.3 Tests.

1.4.3.1 Whenever the authority having jurisdiction determines that there is insufficient evidence of proof of equivalency with the prescribed requirements of this standard, the authority having jurisdiction shall be authorized to require tests showing proof of equivalency.

1.4.3.2 Tests required by the authority having jurisdiction shall be provided by the owner at no expense to the jurisdiction.

1.4.3.3 Tests shall be conducted as specified in this standard or, where test methods are not specified in this standard, they shall be conducted as required by the authority having jurisdiction.

1.4.4 Approval. The authority having jurisdiction shall determine whether the proposed alternate methods of construction, materials, and designs are at least equivalent to the prescribed requirements of this standard.

1.5 Units.

1.5.1 SI Units. Metric units of measurement in this standard are in accordance with the modernized metric system known as the International System of Units (SI).

1.5.2 Primary Values. The inch-pound value for a measurement, and the SI value given in parentheses, shall each be acceptable for use as primary units for satisfying the requirements of this standard.

Chapter 2 Referenced Publications

2.1 General. The documents or portions thereof listed in this chapter are referenced within this standard and shall be considered part of the requirements of this document.

2.2 NFPA Publications. National Fire Protection Association, 1 Batterymarch Park, Quincy, MA 02169-7471.

NFPA 10, *Standard for Portable Fire Extinguishers,* 2013 edition.

NFPA 13, *Standard for the Installation of Sprinkler Systems,* 2013 edition.

NFPA 30, *Flammable and Combustible Liquids Code,* 2015 edition.

NFPA 31, *Standard for the Installation of Oil-Burning Equipment,* 2011 edition.

NFPA 54, *National Fuel Gas Code,* 2015 edition.

NFPA 58, *Liquefied Petroleum Gas Code,* 2014 edition.

NFPA 70®, National Electrical Code®, 2014 edition.

NFPA 72®, National Fire Alarm and Signaling Code, 2013 edition.

NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems,* 2015 edition.

NFPA 90B, *Standard for the Installation of Warm Air Heating and Air-Conditioning Systems,* 2015 edition.

NFPA 91, *Standard for Exhaust Systems for Air Conveying of Vapors, Gases, Mists, and Particulate Solids,* 2015 edition.

NFPA *101®, Life Safety Code®,* 2015 edition.

NFPA 160, *Standard for the Use of Flame Effects Before an Audience,* 2011 edition.

NFPA 211, *Standard for Chimneys, Fireplaces, Vents, and Solid Fuel–Burning Appliances,* 2013 edition.

NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films,* 2015 edition.

NFPA 1126, *Standard for the Use of Pyrotechnics Before a Proximate Audience*, 2011 edition.

NFPA 5000®, Building Construction and Safety Code®, 2015 edition.

2.3 Other Publications.

2.3.1 ASCE Publications. American Society of Civil Engineers, 1801 Alexander Bell Drive, Reston, VA 20191-4400.

ASCE/SEI 17, *Air Supported Structures*, 1996.

2.3.2 ASTM Publications. ASTM International, 100 Barr Harbor Drive, P.O. Box C700, West Conshohocken, PA 19428-2959.

ASTM A 153/A 153M, *Standard Specification for Zinc Coating (Hot-Dip) on Iron and Steel Hardware*, 2009.

ASTM D 2898, *Standard Practice for Accelerated Weathering of Fire-Retardant-Treated Wood for Fire Testing*, 2010.

ASTM G 155, *Standard Practice for Operating Xenon Arc Light Apparatus for Exposure of Non-Metallic Materials*, 2005a.

2.3.3 IAPMO Publications. International Association of Plumbing and Mechanical Officials, 5000 E. Philadelphia Street, Ontario, CA 91761.

UMC, *Uniform Mechanical Code*, 2012.

2.3.4 Other Publications.

Merriam-Webster's Collegiate Dictionary, 11th edition, Merriam-Webster, Inc., Springfield, MA, 2003.

2.4 References for Extracts in Mandatory Sections.

NFPA *101®*, *Life Safety Code®*, 2015 edition.

NFPA 5000®, Building Construction and Safety Code®, 2015 edition.

Chapter 3 Definitions

3.1 General. The definitions contained in this chapter shall apply to the terms used in this standard. Where terms are not defined in this chapter or within another chapter, they shall be defined using their ordinarily accepted meanings within the context in which they are used. *Merriam-Webster's Collegiate Dictionary*, 11th edition, shall be the source for the ordinarily accepted meaning.

3.2 NFPA Official Definitions.

3.2.1* Approved. Acceptable to the authority having jurisdiction.

3.2.2* Authority Having Jurisdiction (AHJ). An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

3.2.3* Code. A standard that is an extensive compilation of provisions covering broad subject matter or that is suitable for adoption into law independently of other codes and standards.

3.2.4 Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

3.2.5* Listed. Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

3.2.6 Shall. Indicates a mandatory requirement.

3.2.7 Should. Indicates a recommendation or that which is advised but not required.

3.2.8 Standard. An NFPA Standard, the main text of which contains only mandatory provisions using the word "shall" to indicate requirements and that is in a form generally suitable for mandatory reference by another standard or code or for adoption into law. Nonmandatory provisions are not to be considered a part of the requirements of a standard and shall be located in an appendix, annex, footnote, informational note, or other means as permitted in the NFPA Manuals of Style. When used in a generic sense, such as in the phrase "standards development process" or "standards development activities," the term "standards" includes all NFPA Standards, including Codes, Standards, Recommended Practices, and Guides.

3.3 General Definitions.

3.3.1 Air-Inflated Structure. A structure whose shape is maintained by air pressure in cells or tubes forming all or part of the enclosure of the usable area and in which the occupants are not within the pressurized area used to support the structure. [**5000,** 2015]

3.3.2* Air-Supported Structure. A structure where shape is maintained by air pressure and in which occupants are within the elevated pressure area. [**5000,** 2015]

3.3.3* Assembly Occupancy. An occupancy (1) used for a gathering of 50 or more persons for deliberation, worship, entertainment, eating, drinking, amusement, awaiting transportation, or similar uses; or (2) used as a special amusement building, regardless of occupant load. [**5000,** 2015]

3.3.4 Bleachers. A grandstand in which the seats are not provided with backrests. [**5000,** 2015]

3.3.5* Exit. That portion of a means of egress that is separated from all other spaces of a building or structure by construction, location, or equipment as required to provide a protected way of travel to the exit discharge. [**5000,** 2015]

3.3.6 Exit Access. That portion of a means of egress that leads to an exit. [**5000,** 2015]

3.3.7 Exit Discharge. That portion of a means of egress between the termination of an exit and a public way. [**5000,** 2015]

3.3.8 Fire Resistance Rating. The time, in minutes or hours, that materials or assemblies have withstood a fire exposure as determined by the tests, or methods based on tests, prescribed by *NFPA 5000*. [**5000,** 2015]

3.3.9 Folding and Telescopic Seating. A structure that is used for tiered seating of persons and whose overall shape and size can be reduced, without being dismantled, for purposes of moving or storing. [***101,*** 2015]

3.3.10* Grandstand. A structure that provides tiered or stepped seating. [**5000,** 2015]

3.3.11 Limited-Combustible (Material). See 7.1.4.2 of *NFPA 5000*.

3.3.12* Means of Egress. A continuous and unobstructed way of travel from any point in a building or structure to a public way consisting of three separate and distinct parts: (1) the exit access, (2) the exit, and (3) the exit discharge. [**5000,** 2015]

3.3.13 Membrane. A thin layer of construction material. [**5000,** 2015]

3.3.14 Membrane Structure. A building or portion of a building incorporating an air-inflated, air-supported, tensioned-membrane structure; a membrane roof; or a membrane-covered rigid frame to protect habitable or usable space. [**5000,** 2015]

3.3.15 Noncombustible Material. See 7.1.4.1 of *NFPA 5000*.

3.3.16 Permanent. Any object that is intended to remain in place for more than 180 days in any consecutive 12-month period. [**5000,** 2015]

3.3.17 Private Party Tent. A tent erected in the yard of a private residence for entertainment, recreation, dining, a reception, or similar function. [**5000,** 2015]

3.3.18 Professional Engineer. A person registered or licensed to practice engineering in a jurisdiction, subject to all laws and limitations imposed by the jurisdiction. [**5000,** 2015]

3.3.19 Tensioned-Membrane Structure. A membrane structure incorporating a membrane and a structural support system such as arches, columns and cables, or beams wherein the stresses developed in the tensioned membrane interact with those in the structural support so that the entire assembly acts together to resist the applied loads. [**5000,** 2015]

3.3.20* Tent. A temporary structure, the covering of which is made of pliable material that achieves its support by mechanical means such as beams, columns, poles, or arches, or by rope or cables, or both. [**5000,** 2015]

3.3.21 Weathered-Membrane Material. Membrane material that has been subjected to a minimum of 3000 hours in a weatherometer in accordance with ASTM G 155, *Standard Practice for Operating Xenon Arc Light Apparatus for Exposure of Non-Metallic Materials*, or approved equivalent. [***101,*** 2015]

Chapter 4 Means of Egress

4.1 New Facilities. New facilities included within the scope of this standard shall comply with one of the following:

(1) The means of egress provisions of NFPA *101* for the applicable occupancies
(2) The means of egress provisions of *NFPA 5000* for the applicable occupancies

4.2 Existing Facilities. Existing facilities included within the scope of this standard shall comply with the means of egress provisions of NFPA *101* for the applicable occupancies.

Chapter 5 Grandstands and Bleachers

5.1 General. Grandstands and bleachers shall comply with the requirements of this chapter. [**5000:**32.7.1]

5.2 Location. Grandstands shall be erected or otherwise located only where load-carrying capacities exist to support the loads. [**5000:**32.7.2]

5.3 Minimum Construction Requirements. [**5000:**32.7.3]

5.3.1 Grandstands and bleachers shall be permitted to be of unlimited area when of Type I or Type II construction. [**5000:**32.7.3.1]

5.3.2 Grandstands and bleachers shall be permitted to be of Type III, Type IV, or Type V construction when designed in accordance with Section 5.7. [**5000:**32.7.3.2]

5.4 Design. [**5000:**32.7.4]

5.4.1 Grandstands shall be designed to withstand the structural loading requirements of Chapter 35 of *NFPA 5000* unless otherwise permitted by 5.4.2. [**5000:**32.7.4.1]

5.4.2 The manufacturer shall comply with the requirements of 5.4.2.1 and 5.4.2.2. [**5000:**32.7.4.2]

5.4.2.1 Where required by the authority having jurisdiction, the manufacturer shall submit either of the following:

(1) Calculations verifying the design analysis prepared by a professional engineer or registered architect
(2) Report of load tests conducted by an approved, independent testing laboratory and certified by a professional engineer

[**5000:**32.7.4.2.1]

5.4.2.2 Where required by the authority having jurisdiction, the manufacturer shall certify that the equipment supplied is in accordance with the design. [**5000:**32.7.4.2.2]

5.5 Seating. [**5000:**16.4.9.2]

5.5.1 Where grandstand seating without backs is used indoors, rows of seats shall be spaced not less than 22 in. (560 mm) back-to-back. [**5000:**16.4.9.2.1]

5.5.2 The depth of footboards and seat boards in grandstands shall be not less than 9 in. (230 mm). Where the same level is not used for both seat foundations and footrests, footrests independent of seats shall be provided. [**5000:**16.4.9.2.2]

5.5.3 Seats and footrests of grandstands shall be supported securely and fastened in such a manner that they cannot be displaced inadvertently. [**5000:**16.4.9.2.3]

5.5.4 Individual seats or chairs shall be permitted only if secured in rows in an approved manner, unless the seats do not exceed 16 in number and are located on level floors and within railed-in enclosures, such as boxes. [**5000:**16.4.9.2.4]

5.5.5 The maximum number of seats permitted between the farthest seat in an aisle in grandstands and bleachers shall not exceed that shown in Table 5.5.5. [**5000:**16.4.9.2.5]

Table 5.5.5 Maximum Number of Seats Permitted Between Farthest Seat and an Aisle

Application	Outdoors	Indoors
Grandstands	11	6
Bleachers	20	9

[**5000:** Table 16.4.9.2.5]

5.5.6 Vertical openings between guardrails and footboards or seat boards shall be provided with intermediate construction so that a 4 in. (100 mm) diameter sphere cannot pass through the opening. [**5000:**16.4.9.6.7]

5.5.7 An opening between the seat board and footboard located more than 30 in. (760 mm) above grade shall be provided with intermediate construction so that a 4 in. (100 mm) diameter sphere cannot pass through the opening. [**5000:**16.4.9.6.8]

5.6 Guards and Railings. [**5000:**16.4.9.6]

5.6.1 Railings or guards not less than 42 in. (1065 mm) above the aisle surface or footrest or not less than 36 in. (915 mm) vertically above the center of the seat or seat board surface, whichever is adjacent, shall be provided along those portions of the backs and ends of all grandstands where the seats are more than 48 in. (1220 mm) above the floor or ground. [**5000:**16.4.9.6.1]

5.6.2 The requirement of 5.6.1 shall not apply where an adjacent wall or fence affords equivalent safeguard. [**5000:**16.4.9.6.2]

5.6.3 Where the front footrest of any grandstand is more than 24 in. (610 mm) above the floor, railings or guards not less than 33 in. (825 mm) above such footrests shall be provided. [**5000:**16.4.9.6.3]

5.6.4 The railings required by 5.6.3 shall be permitted to be not less than 26 in. (660 mm) high in grandstands or where the front row of seats includes backrests. [**5000:**16.4.9.6.4]

5.6.5 Cross aisles located within the seating area shall be provided with rails not less than 26 in. (660 mm) high along the front edge of the cross aisle. [**5000:**16.4.9.6.5]

5.6.6 The railings specified by 5.6.5 shall not be required where the backs of the seats in front of the cross aisle project 24 in. (610 mm) or more above the surface of the cross aisle. [**5000:**16.4.9.6.6]

5.6.7 Vertical openings between guardrails and footboards or seat boards shall be provided with intermediate construction so that a 4 in. (100 mm) diameter sphere cannot pass through the opening. [**5000:**16.4.9.6.7]

5.6.8 An opening between the seat board and footboard located more than 30 in. (760 mm) above grade shall be provided with intermediate construction so that a 4 in. (100 mm) diameter sphere cannot pass through the opening. [**5000:**16.4.9.6.8]

5.7 Special Requirements — Type III, Type IV, and Type V Grandstands. [**5000:**32.7.5]

5.7.1 An outdoor grandstand of Type III, Type IV, or Type V construction shall not be erected a distance less than two-thirds of its height from a building, but in no case shall the grandstand be erected less than 10 ft (3050 mm) from a building, unless one of the following criteria is met:

(1) The exterior wall of the building is of at least 1-hour fire resistance–rated construction with all openings protected.
(2) A fire wall of at least 1-hour fire resistance–rated construction is provided between the grandstand and the building.

[**5000:**32.7.5.1]

5.7.2 The following shall apply to outdoor grandstand units of Type III, Type IV, or Type V construction:

(1) No outdoor grandstand unit shall exceed 10,000 ft^2 (930 m^2) or 200 ft (61 m) in length.
(2) Grandstand units of the maximum size shall be placed not less than 20 ft (6100 mm) apart or shall be separated by walls with a 1-hour fire resistance rating.
(3) Not more than three units shall be erected in any one group.
(4) Each group of less than three units shall be separated from any other group by a wall of 2-hour fire resistance-rated construction extending 24 in. (610 mm) above the seat platforms or by an open space of not less than 50 ft (15 m).
(5) Where entirely constructed of labeled fire retardant–treated wood that has passed the standard rain test in ASTM D 2898, *Standard Practice for Accelerated Weathering of Fire-Retardant-Treated Wood for Fire Testing*, or where constructed of members conforming to dimensions for heavy timber construction [Type IV (2HH)], the area or length specified by 5.7.2(1) shall be permitted to be doubled.

[**5000:**32.7.5.2]

5.7.3 The highest level of seat platforms above the ground or the surface at the front of the grandstand shall be as follows:

(1) Grandstands of Type III, Type IV, or Type V construction — not more than 20 ft (6100 mm)
(2) Portable grandstands of Type III, Type IV, or Type V construction within tents or membrane structures — not more than 12 ft (3660 mm)

[**5000:**32.7.5.3]

5.7.4 Where entirely constructed of labeled fire retardant–treated wood that has passed the standard rain test in ASTM D 2898 or where constructed of members conforming to dimensions for heavy timber construction [Type IV (2HH)], the heights specified by 5.7.3 shall be permitted to be doubled. [**5000:**32.7.5.4]

5.8 Special Requirements — Portable Grandstands. Portable grandstands shall conform to the requirements of this chapter for grandstands and the special requirements of Section 5.8. [**5000:**32.7.6]

5.8.1 General. Portable grandstands shall comply with the following:

(1) Portable grandstands shall be self-contained, having within them all necessary parts to withstand and restrain all forces that might be developed during human occupancy.
(2) Portable grandstands shall be designed and manufactured so that, if any structural members required for the strength and stability of the structure have been omitted during erection, the presence of unused connection fittings shall make the omissions self-evident.
(3) The construction shall produce the strength required by the design.
(4) Portable grandstands shall not be used until all parts have been erected, or re-erected, in accordance with the approved design and specifications.
(5) The seating, walkways, railings, bracing, and supporting members shall be structurally sound.

[**5000:**32.7.6.1]

5.8.2 Placement. The following shall apply to the placement of portable grandstands:

(1) Portable grandstands shall be provided with base plates, sills, floor runners, or sleepers of such area that the allowable bearing capacity of the supporting material is not exceeded.
(2) Where portable grandstands rest directly on a base where settlement can or does occur beyond that allowed by design, mud sills of suitable material having sufficient area to prevent undue or dangerous settlement shall be installed under base plates, runners, or sleepers.
(3) All bearing surfaces shall be in full contact with each other.

[**5000:**32.7.6.2]

5.8.3 Prevention of Displacement. A-frames or other supports and seat stringers for portable grandstands shall be secured to prevent accidental displacement during occupancy. [**5000:**32.7.6.3]

5.8.4 Fasteners. The following shall apply to fasteners for portable grandstands:

(1) The use of nails, lag screws, and wood screws shall be permitted for holding wood parts together, provided that the following criteria are met:
    (a) Nails, lag screws, and wood screws shall not be used for demountable joinings.
    (b) Nails, lag screws, and wood screws shall not be used where their loosening or splitting of surrounding wood would jeopardize the structure or its occupants.
(2) Members in tension shall be connected at each end by not less than two bolts, rivets, or lag screws or by approved connectors or other approved devices.
(3) All ferrous fastenings and fastening devices shall be stainless steel or hot-dipped galvanized in accordance with ASTM A 153/A 153M, *Standard Specification for Zinc Coating (Hot-Dip) on Iron and Steel Hardware.*

[**5000:**32.7.6.4]

5.9 Spaces Underneath Grandstands. Spaces underneath a grandstand shall be kept free of flammable or combustible materials, unless protected by an approved, electrically supervised automatic sprinkler system in accordance with NFPA 13 unless otherwise permitted by the following:

(1) This requirement shall not apply to accessory uses of 300 ft^2 (27.9 m^2) or less, such as ticket booths, toilet facilities, or concession booths where constructed of noncombustible, limited-combustible, or fire-resistive construction, in otherwise nonsprinklered facilities.
(2) This requirement shall not apply to rooms enclosed in not less than 1-hour fire resistance–rated construction that are of less than 1000 ft^2 (93 m^2), in otherwise nonsprinklered facilities.

[**5000:**16.4.9.5]

5.10 Maintenance. Maintenance shall be provided as follows:

(1) The owner shall provide for not less than annual inspection and required maintenance of each grandstand to ensure safe conditions.
(2) At least biennially, the inspection shall be performed by a professional engineer or registered architect.
(3) Where required by the authority having jurisdiction, the owner shall provide certification that both inspections have been performed.

[**5000:**32.7.7]

Chapter 6 Folding and Telescopic Seating

6.1 Application. Folding and telescopic seating shall be permitted only if the supporting structure has been designed to handle the loading and has the exit facilities to accommodate the occupants of the seating, as well as all other occupants. [**5000:**32.7.8.1]

6.2 Design. [**5000:**32.7.8.2]

6.2.1 Structural Loading. The design of folding and telescopic seating shall withstand the structural loading requirements of Chapter 35 of *NFPA 5000.* [**5000:**32.7.8.2.1]

6.2.2 Load Tests. Load tests in accordance with accepted engineering practice shall be permitted in lieu of the design analysis for a seating unit or part thereof. [**5000:**32.7.8.2.2]

6.2.3 Manufacturer Requirements. The manufacturer shall comply with the requirements of 6.2.3.1 and 6.2.3.2. [**5000:**32.7.8.2.3]

6.2.3.1 Where required by the authority having jurisdiction, the manufacturer shall submit either of the following:

(1) Calculations verifying the design analysis prepared by a professional engineer or registered architect
(2) Report of load tests conducted by an approved, independent testing laboratory and certified by a professional engineer

[**5000:**32.7.8.2.3.1]

6.2.3.2 Where required by the authority having jurisdiction, the manufacturer shall certify that the equipment supplied is in accordance with the design or is essentially identical to the structure tested. [**5000:**32.7.8.2.3.2]

6.3 Review and Approval. [**5000:**32.7.8.2.4]

6.3.1 Design and installation drawings shall be approved prior to installation, and seating shall be installed in conformance with such drawings. [**5000:**32.7.8.2.4.1]

6.3.2 The drawings shall include the following:

(1) Conformance with approved designs, which are permitted to refer to approved standard drawings, with any variations applicable to the job noted
(2) Location of the folding or telescopic seating units and details of attachments, if any
(3) Location of guards and details thereof
(4) Capability of means of egress to accommodate the occupants of the seating, as well as all other occupants, based on Chapter 11 of *NFPA 5000*
(5) Structural capacity of the site to support the folding and telescopic seating dead loads when closed and also to support the dead loads and live loads when open

[**5000:**32.7.8.2.4.2]

6.4 Seating. [**5000:**16.4.10.2]

6.4.1 The horizontal distance of seats, measured back-to-back, shall be not less than 22 in. (560 mm) for seats without backs, and the following requirements shall also apply:

(1) There shall be a space of not less than 12 in. (305 mm) between the back of each seat and the front of each seat immediately behind it.
(2) If seats are of the chair type, the 12 in. (305 mm) dimension shall be measured to the front edge of the rear seat in its normal, unoccupied position.
(3) All measurements shall be taken between plumb lines.

[**5000:**16.4.10.2.1]

6.4.2 The depth of footboards (footrests) and seat boards in folding and telescopic seating shall be not less than 9 in. (230 mm). [**5000:**16.4.10.2.2]

6.4.3 Where the same level is not used for both seat foundations and footrests, footrests independent of seats shall be provided. [**5000:**16.4.10.2.2]

6.4.4 Individual chair-type seats shall be permitted in folding and telescopic seating only if firmly secured in groups of not less than three. [**5000:**16.4.10.2.3]

6.4.5 The maximum number of seats permitted between the furthest seat in an aisle in folding and telescopic seating shall not exceed that shown in Table 5.5.5. [**5000:**16.4.10.2.4]

6.4.6 An opening between the seat board and footboard located more than 30 in. (760 mm) above grade shall be provided with intermediate construction so that a 4 in. (100 mm) diameter sphere cannot pass through the opening. [**5000:**16.4.10.3.8]

6.5 Guards and Railings. [**5000:**16.4.10.3]

6.5.1 Guards. Guards in accordance with Chapter 11 of *NFPA 5000* shall be provided at the open sides of means of egress that exceed 30 in. (760 mm) above the floor or grade below, except as otherwise permitted by 6.5.2 through 6.5.9. [**5000:**11.1.8]

6.5.2 Railings or guards not less than 42 in. (1065 mm) above the aisle surface or footrest, or not less than 36 in. (915 mm) vertically above the center of the seat or seat board surface, whichever is adjacent, shall be provided along those portions of the backs and ends of all folding and telescopic seating where the seats are more than 48 in. (1220 mm) above the floor or ground. [**5000:**16.4.10.3.1]

6.5.3 The requirement of 6.5.2 shall not apply where an adjacent wall or fence affords equivalent safeguard. [**5000:**16.4.10.3.2]

6.5.4 Where the front footrest of folding or telescopic seating is more than 24 in. (610 mm) above the floor, railings or guards not less than 33 in. (825 mm) above such footrests shall be provided. [**5000:**16.4.10.3.3]

6.5.5 The railings required by 6.5.4 shall be permitted to be not less than 26 in. (660 mm) high where the front row of seats includes backrests. [**5000:**16.4.10.3.4]

6.5.6 Cross aisles located within the seating area shall be provided with rails not less than 26 in. (660 mm) high along the front edge of the cross aisle. [**5000:**16.4.10.3.5]

6.5.7 The railings specified by 6.5.6 shall not be required where the backs of the seats in front of the cross aisle project 24 in. (610 mm) or more above the surface of the cross aisle. [**5000:**16.4.10.3.6]

6.5.8 Vertical openings between guardrails and footboards or seat boards shall be provided with intermediate construction so that a 4 in. (100 mm) diameter sphere cannot pass through the opening. [**5000:**16.4.10.3.7]

6.5.9 An opening between the seat board and footboard located more than 30 in. (760 mm) above grade shall be provided with intermediate construction so that a 4 in. (100 mm) diameter sphere cannot pass through the opening. [**5000:**16.4.10.3.8]

6.6 Maintenance and Operation of Folding and Telescopic Seating. [***101*:**12.7.11]

6.6.1 Instructions in both maintenance and operation shall be transmitted to the owner by the manufacturer of the seating or his or her representative. [***101*:**12.7.11.1]

6.6.2 Maintenance and operation of folding and telescopic seating shall be the responsibility of the owner or his or her duly authorized representative and shall include the following:

(1) During operation of the folding and telescopic seats, the opening and closing shall be supervised by responsible personnel who shall ensure that the operation is in accordance with the manufacturer's instructions.
(2) Only attachments specifically approved by the manufacturer for the specific installation shall be attached to the seating.
(3) An annual inspection and required maintenance of each folding and telescopic seating unit shall be performed to ensure safe conditions.
(4) At least biennially, the inspection shall be performed by a professional engineer, registered architect, or individual certified by the manufacturer.

[***101*:**12.7.11.2]

Chapter 7 Membrane Structures

7.1 General. [**5000:**32.2.1]

7.1.1 Scope. Chapter 7 shall apply to permanent air-supported, air-inflated, and tensioned-membrane structures, collectively known as membrane structures, that are used as complete buildings and as roofs or other portions of buildings or other types of construction, and the following also shall apply:

(1) Membrane structures also shall comply with the applicable provisions of *NFPA 5000*.
(2) Temporary membrane structures shall comply with Section 7.5.

[**5000:**32.2.1.1]

7.1.1.1 General. Membrane structures that provide the complete enclosure for the occupied space shall be considered as complete buildings and subject to the requirements of this chapter. [**5000:**32.2.1.1.1]

7.1.1.2 Height. Membrane structures shall be limited to one story in height, but height shall not be limited in number of feet (meters). [**5000:**32.2.1.1.2]

7.1.1.3 Area. For determining allowable area, the construction type for a membrane structure shall be based on the support system. [**5000:**32.2.1.1.3]

7.1.1.3.1 Air-supported membrane structures shall not exceed the allowable areas listed in Chapter 7 of *NFPA 5000* for Type II(000) unprotected construction. [**5000:**32.2.1.1.3.1]

7.1.1.3.2 Area increases in accordance with Chapter 7 of *NFPA 5000* shall be permitted. [**5000:**32.2.1.1.3.2]

7.1.2 Structural Design. Membrane structures, and portions thereof shall be designed and constructed to support, within the limitations specified by *NFPA 5000,* all loads set forth in Chapter 35 and elsewhere in *NFPA 5000* and combined in accordance with Section 35.15 of *NFPA 5000.* [**5000:**35.1.2]

7.1.3 Electrical. Electrical wiring shall comply with *NFPA 70.* [**5000:**32.2.1.3]

7.1.4 Fire Protection Systems and Equipment. All membrane structures shall be in accordance with Chapter 55 of *NFPA 5000.* [**5000:**32.2.1.4]

7.1.5 Mechanical. [**5000:**32.2.1.5]

7.1.5.1 Fuel gas heating, ventilation, and air-conditioning installations shall conform to the requirements of NFPA 54. [**5000:**32.2.1.5.1]

7.1.5.2 The installation of equipment not covered in 7.1.5.1 shall conform to the requirements of the UMC, *Uniform Mechanical Code.* [**5000:**32.2.1.5.2]

7.1.6 Occupancy Separation. A membrane structure building that is occupied by more than one use group shall comply with Chapter 6 of *NFPA 5000.* [**5000:**32.2.1.6]

7.1.7 Mixed Construction. [**5000:**32.2.1.7]

7.1.7.1 Membrane structures shall be permitted to be utilized as a portion of buildings of other types of construction as specified in this chapter. [**5000:**32.2.1.7.1]

7.1.7.2 Height and area limits shall be as specified for the type of construction and occupancy of the building. [**5000:**32.2.1.7.2]

7.2 Permanent Membrane Structures. [**5000:**32.2.2]

7.2.1 Testing. Testing of membrane materials for compliance with the requirements of this chapter for use of the categories of noncombustible and limited-combustible materials shall be performed on weathered-membrane material, as defined in Section 3.3. [***101*:**11.9.1.3]

7.2.2 Use of Membrane Materials. Membrane materials shall not be used where fire resistance ratings are required for walls or roofs, unless otherwise permitted by the following:

(1) Where every part of the roof, including the roof membrane, is not less than 20 ft (6100 mm) above any floor, balcony, or gallery, a noncombustible or limited-combustible membrane shall be permitted to be used as the roof in any type of construction.
(2) With approval of the authority having jurisdiction, membrane materials shall be permitted to be used where every part of the roof membrane is located sufficiently above every significant fire potential so that the imposed temperature will not exceed the capability of the membrane, including seams, to maintain its structural integrity.

[**5000:**32.2.2.1]

7.2.3 Flame Spread. [**5000:**32.2.2.2]

7.2.3.1 Flame spread of all membrane materials exposed within the structure shall be Class A, as defined in Chapter 10 of *NFPA 5000.* [**5000:**32.2.2.2.1]

7.2.3.2 The requirement of 7.2.3.1 shall not apply to plastic less than 20 mil (0.51 mm) in thickness located less than 30 ft (9100 mm) above any floor in greenhouses where occupancy by the general public is prohibited. [**5000:**32.2.2.3.2]

7.2.4 Flame Resistance. [**5000:**32.2.2.3]

7.2.4.1 All membrane structure fabric shall meet the requirements of Test Method 2 contained in NFPA 701. [**5000:**32.2.2.3.1]

7.2.4.2 The requirement of 7.2.4.1 shall not apply to plastic less than 20 mil (0.51 mm) in thickness located less than 30 ft (9100 mm) above any floor in greenhouses where occupancy by the general public is prohibited. [**5000:**32.2.2.3.2]

7.2.4.3 The authority having jurisdiction shall require one of the following as evidence that membrane structure fabric materials have the required flame resistance:

(1) Certificate or other evidence of acceptance by an organization acceptable to the authority having jurisdiction
(2) Report of tests made by other inspection authorities or organizations acceptable to the authority having jurisdiction

[**5000:**32.2.2.3.3]

7.2.4.4 Where required by the authority having jurisdiction, confirmatory field tests shall be conducted using test specimens from the original material affixed at the time of manufacture to the exterior of the structure. [**5000:**32.2.2.3.4]

7.3 Tensioned-Membrane Structures. [**5000:**32.2.3]

7.3.1 Protection for Membrane Roofs. Protection for membrane roofs for structures in climates subject to freezing temperatures and ice buildup shall be as specified in 7.3.1.1 or 7.3.1.2. [**5000:**32.2.3.1]

7.3.1.1 The roof shall be composed of two layers with an air space between the layers through which heated air can be moved to guard against ice accumulation. [**5000:**32.2.3.1.1]

7.3.1.2 Any approved methods that protect against ice accumulation shall be permitted. [**5000:**32.2.3.1.2]

7.3.2* Protection for Roof Drains. Protection for roof drains shall be as specified in 7.3.2.1 and 7.3.2.2 or 7.3.2.3. [**5000:**32.2.3.2]

7.3.2.1 Roof drains shall be equipped with listed de-icing and snow-melting equipment to protect against ice buildup, which would prevent the drains from functioning. [**5000:**32.2.3.2.1]

7.3.2.2 The equipment specified in 7.3.2.1 shall be served by on-site standby electrical power in addition to the normal public service. [**5000:**32.2.3.2.2]

7.3.2.3 In lieu of de-icing and snow-melting equipment, any other approved methods that protect against ice accumulation shall be permitted. [**5000:**32.2.3.2.3]

7.4 Air-Supported, Air-Inflated Structures. [**5000:**32.2.4]

7.4.1* General. In addition to the requirements of this chapter, air-supported structures shall be designed and operated in accordance with ASCE/SEI 17, *Air Supported Structures.* [**5000:**32.2.4.1]

7.4.2 Maintenance and Operation. [**5000:**32.2.4.2]

7.4.2.1 Instructions in both operation and maintenance shall be transmitted to the owner by the manufacturer of the tensioned-membrane, air-supported, or air-inflated structure. [**5000:**32.2.4.2.1]

7.4.2.2 An annual inspection and required maintenance of each structure shall be performed. [**5000:**32.2.4.2.2]

7.4.2.3 At least biennially, the annual inspection shall be performed by a professional engineer or qualified service representative. [**5000:**32.2.4.2.3]

7.5 Temporary Membrane Structures. [**5000:**32.2.5]

7.5.1 General. Membrane structures designed to meet all the requirements of this chapter shall be permitted to be used as temporary buildings subject to the approval of the authority having jurisdiction. [**5000:**32.2.5.1]

7.5.2 Temporary Membrane Structures. Temporary membrane structures shall comply with the requirements of Section 7.5 and 7.2.4. [**5000:**32.2.5.2]

7.5.3* Temporary Tensioned-Membrane Structures. Temporary tensioned-membrane structures shall be permitted to comply with Chapter 8, provided that the following criteria are met:

(1) Roof drains shall be equipped with listed de-icing and snow-melting equipment.
(2) The de-icing and snow-melting equipment shall be served by on-site standby electrical power in addition to the normal public service.
(3) Any approved methods that protect against ice accumulation shall be permitted.

[**5000:**32.2.5.3]

7.5.4 Clearance. There shall be a minimum clearance of 36 in. (915 mm) between the membrane and the contents or equipment within the building and between the membrane and any exterior object. [**5000:**32.2.5.4]

7.5.5 Fire Hazards.

7.5.5.1 Temporary membrane structures shall be protected as specified in 7.5.5.1.1 through 7.5.5.1.4. [**5000:**32.3.5.1]

7.5.5.1.1 The finished ground level enclosed by the structure, and the surrounding finished ground level not less than 10 ft (3050 mm) outside of the structure, shall be cleared of all flammable or combustible material and vegetation. [**5000:**32.3.5.1.1]

7.5.5.1.2 The requirement of 7.5.5.1.1 shall be accomplished to the satisfaction of the authority having jurisdiction prior to the erection of tents and temporary membrane structures. [**5000:**32.3.5.1.2]

7.5.5.1.3 The premises shall be kept free from flammable or combustible materials during the period for which the premises are used by the public. [**5000:**32.3.5.1.3]

7.5.5.1.4 The requirements of 7.5.5.1.1 through 7.5.5.1.3 shall not apply to necessary support equipment. [**5000:**32.3.5.1.4]

7.5.5.2 Containers for liquefied petroleum gases shall be installed not less than 60 in. (1525 mm) from any temporary membrane structure and shall be in accordance with the provisions of NFPA 58. [***101*:**11.9.5.1.3]

7.5.5.3 Tanks shall be secured in the upright position and protected from vehicular traffic. [***101*:**11.9.5.1.4]

Chapter 8 Tents

8.1 General. [***101*:**11.11.1]

8.1.1 The provisions of Chapter 8 shall apply to tents. [***101*:**11.11.1.1]

8.1.2 Tents shall be permitted only on a temporary basis. [***101*:**11.11.1.2]

8.1.3 Tents shall be erected to cover not more than 75 percent of the premises, unless otherwise approved by the authority having jurisdiction. [***101*:**11.11.1.3]

8.2 Structural Design Load Requirements. Tents, other than private party tents and camping tents, under 400 ft^2 (37.2 m^2), shall comply with the requirements of Chapter 35 of *NFPA 5000* for structural design loads. [**5000:**32.3.1, 32.3.2]

8.3 Flame Propagation Performance. [**5000:**32.3.3]

8.3.1 All tent fabric shall meet the flame propagation performance criteria of Test Method 2, as required in NFPA 701. [**5000:**32.3.3.1]

8.3.2 The authority having jurisdiction shall require one of the following as evidence that the fabric materials have the required flame propagation performance:

(1) Certificate or other evidence of acceptance by an organization acceptable to the authority having jurisdiction
(2) Report of tests made by other inspection authorities or organizations acceptable to the authority having jurisdiction

[**5000:**32.3.3.2]

8.3.3 Where required by the authority having jurisdiction, confirmatory field tests shall be conducted using test specimens from the original material affixed at the time of manufacture to the exterior of the tent. [**5000:**32.3.3.3]

8.4 Location and Spacing. [**5000:**32.3.4]

8.4.1 There shall be a minimum of 10 ft (3050 mm) between stake lines. [**5000:**32.3.4.1]

8.4.2 Adjacent tents shall meet the requirements of 8.4.2.1 and 8.4.2.2. [**5000:**32.3.4.2]

8.4.2.1 Adjacent tents shall be no closer to each other than allowed in order to provide an area to be used as a means of emergency egress as calculated in accordance with Chapter 11 of *NFPA 5000*. [**5000:**32.3.4.2.1]

8.4.2.2 Where 10 ft (3050 mm) between stake lines is not sufficient for means of egress, the distance necessary for means of egress shall govern. [**5000:**32.3.4.2.2]

8.4.3 Subject to the approval of the authority having jurisdiction, the requirements of 8.4.2 shall not apply, provided that the following criteria are met:

(1) Tents not occupied by the public and not used for the storage of combustible material shall be permitted to be erected less than 10 ft (3050 mm) from other structures.
(2) Tents, each not exceeding 1200 ft^2 (110 m^2), and located in fairgrounds or similar open spaces, shall not be required to be separated from each other.

[**5000:**32.3.4.3]

8.4.4 The placement of tents relative to other structures shall be at the discretion of the authority having jurisdiction, based on the occupancy, use, opening, exposure, and other similar factors. [**5000:**32.3.4.4]

8.5 Fire Hazards. [***101*:**11.11.4]

8.5.1 Smoking shall not be permitted in any tent unless approved by the authority having jurisdiction. [***101*:**11.11.4.2.1]

8.5.2 Tents shall be protected as specified in 8.5.2.1 through 8.5.2.4. [**5000:**32.3.5.1]

8.5.2.1 The finished ground level enclosed by the structure, and the surrounding finished ground level not less than 10 ft (3050 mm) outside of the structure, shall be cleared of all flammable or combustible material and vegetation. [**5000:**32.3.5.1.1]

8.5.2.2 The requirement of 8.5.2.1 shall be accomplished to the satisfaction of the authority having jurisdiction prior to the erection of tents and temporary membrane structures. [**5000:**32.3.5.1.2]

8.5.2.3 The premises shall be kept free from flammable or combustible materials during the period for which the premises are used by the public. [**5000:**32.3.5.1.3]

8.5.2.4 The requirements of 8.5.2.1 through 8.5.2.3 shall not apply to necessary support equipment. [**5000:**32.3.5.1.4]

8.5.3 Containers for liquefied petroleum gases shall be installed not less than 60 in. (1525 mm) from any tent and shall be in accordance with the provisions of NFPA 58. [***101*:**11.11.6.1.3]

8.5.4 Tanks shall be secured in the upright position and protected from vehicular traffic. [***101*:**11.11.6.1.4]

8.6 Portable Fire-Extinguishing Equipment. Portable fire-extinguishing equipment of approved types shall be furnished and maintained in tents in such quantity and in such locations as directed by the authority having jurisdiction. [***101*:**11.11.5]

Chapter 9 Protection

9.1 General. Facilities included within the scope of this standard shall comply with the requirements of this chapter.

9.2 Flammable Liquids and Gases. [***101*:**8.7.3]

9.2.1 The storage and handling of flammable liquids or gases shall be in accordance with the following applicable standards:

(1) NFPA 30
(2) NFPA 54
(3) NFPA 58

[***101*:**8.7.3.1]

9.2.2* No storage or handling of flammable liquids or gases shall be permitted in any location where such storage would jeopardize egress from the structure, unless otherwise permitted by 9.2.1. [***101*:**8.7.3.2]

9.3* Open Flame Devices and Pyrotechnics. No open flame devices or pyrotechnic devices shall be used in any assembly occupancy, unless otherwise permitted by the following:

(1) Pyrotechnic special effect devices shall be permitted to be used on stages before proximate audiences for ceremonial or religious purposes, as part of a demonstration in exhibits, or as part of a performance, provided that both of the following criteria are met:
    (a) Precautions satisfactory to the authority having jurisdiction are taken to prevent ignition of any combustible material.
    (b) Use of the pyrotechnic device complies with NFPA 1126.
(2) Flame effects before an audience shall be permitted in accordance with NFPA 160.
(3) Open flame devices shall be permitted to be used in the following situations, provided that precautions satisfactory to the authority having jurisdiction are taken to prevent ignition of any combustible material or injury to occupants:
    (a) For ceremonial or religious purposes
    (b) On stages and platforms where part of a performance
    (c) Where candles on tables are securely supported on substantial noncombustible bases and candle flame is protected
(4) The requirement of Section 9.3 shall not apply to heat-producing equipment complying with 9.2.2 of NFPA *101*.
(5) The requirement of Section 9.3 shall not apply to food service operations in accordance with 12.7.2 of NFPA *101*.
(6) Gas lights shall be permitted to be used, provided that precautions are taken, subject to the approval of the authority having jurisdiction, to prevent ignition of any combustible materials.

[***101*:**12.7.3]

9.4 Smoking. [***101*:**12.7.8]

9.4.1 Smoking in assembly occupancies shall be regulated by the authority having jurisdiction. [***101*:**12.7.8.1]

9.4.2 In rooms or areas where smoking is prohibited, plainly visible signs shall be posted that read as follows:

NO SMOKING

[***101*:**12.7.8.2]

9.4.3 No person shall smoke in prohibited areas that are so posted, unless permitted by the authority having jurisdiction under both of the following conditions:

(1) Smoking shall be permitted on a stage only where it is a necessary and rehearsed part of a performance.
(2) Smoking shall be permitted only where the smoker is a regular performing member of the cast.

[***101*:**12.7.8.3]

9.4.4 Where smoking is permitted, suitable ashtrays or receptacles shall be provided in convenient locations. [***101*:**12.7.8.4]

9.5 Extinguishment Requirements.

9.5.1 Enclosed stadiums, arenas, and similar structures shall be protected throughout by an approved, electrically supervised automatic sprinkler system in accordance with NFPA 13, unless otherwise permitted by the following:

(1) Where the ceiling or roof, whichever is lower, of the playing/activity area is more than 55 ft (16.7 m) above the floor, sprinklers shall not be required above the playing/activity area where permitted by the authority having jurisdiction.
(2) Sprinklers shall not be required above seating areas that view the playing/activity area.

[**5000:**32.3.5.2]

9.5.2 Any enclosed area shall be protected by an approved sprinkler system in accordance with NFPA 13 unless such an area is one of the following:

(1) Enclosed stadiums, arenas, and similar structures
(2) Press boxes of less than 1000 ft^2 (93 m^2)
(3) Storage facilities of less than 1000 ft^2 (93 m^2) if enclosed with minimum 1-hour fire resistance–rated construction
(4) Enclosed areas underneath grandstands or bleachers that comply with the exemptions of 5.9(1) or 5.9(2)

[**5000:**32.3.5.3]

9.5.3 Portable fire extinguishers shall be installed in assembly occupancies in accordance with NFPA 10 except as otherwise permitted by 9.5.3.1 through 9.5.3.4. [**5000:**16.3.5.3]

9.5.3.1 The requirement of 9.5.3 shall not apply to seating areas. [**5000:**16.3.5.3]

9.5.3.2 The requirement of 9.5.3 shall not apply to floor areas used for contest, performance, or entertainment. [**5000:**16.3.5.3]

9.5.3.3 The requirement of 9.5.3 shall not apply to outside assembly occupancy areas. [**5000:**16.3.5.3]

9.5.3.4 Portable extinguishers shall be permitted to be located in secure locations accessible to staff. [**5000:**16.3.5.3]

9.6 Detection, Alarm, and Communications Systems. [**5000:**16.3.4]

9.6.1 General. [**5000:**16.3.4.1]

9.6.1.1 Assembly occupancies with occupant loads greater than 300 and all theaters with more than one audience-viewing room shall be provided with an approved fire alarm system in accordance with the following, unless otherwise permitted by 9.6.1.2:

(1) Section 55.2 of *NFPA 5000*
(2) 9.6.2 through 9.6.3.7

[**5000:**16.3.4.1.1]

9.6.1.2 Assembly occupancies that are a part of a mixed occupancy shall be permitted to be served by a common fire alarm system, provided that the individual requirements of each occupancy are met. [**5000:**16.3.4.1.2]

9.6.2 Initiation. [**5000:**16.3.4.2]

9.6.2.1 Initiation of the required fire alarm system shall be by the following:

(1) Manual means in accordance with 55.2.2(1) of *NFPA 5000*, unless otherwise permitted by the means that follow:
    (a) The requirement of 9.6.2.1(1) shall not apply where initiation is by means of an approved automatic fire detection system in accordance with Section 55.2 of *NFPA 5000* that provides fire detection throughout the building.
    (b) The requirement of 9.6.2.1(1) shall not apply where initiation is by means of an approved automatic sprinkler system in accordance with Section 55.3 of *NFPA 5000* that provides fire detection and protection throughout the building.
(2) Where automatic sprinklers are provided, initiation of the fire alarm system by means of sprinkler system waterflow, even where manual fire alarm boxes are provided in accordance with 9.6.2.1(1)

[**5000:** 16.3.4.2.1]

9.6.2.2 The initiating device shall be capable of transmitting an alarm to a receiving station, located within the building, that is constantly attended when the assembly occupancy is occupied. [**5000:**16.3.4.2.2]

9.6.2.3* In assembly occupancies with occupant loads greater than 300, automatic detection shall be provided in all hazardous areas that are not normally occupied, unless such areas that are protected throughout by an approved, electrically supervised automatic sprinkler system installed in accordance with NFPA 13. [**5000:**16.3.4.2.3]

9.6.3 Notification. [**5000:**16.3.4.3]

9.6.3.1 The required fire alarm system shall sound an audible alarm in a constantly attended receiving station within the building when occupied for purposes of initiating emergency action. [**5000:**16.3.4.3.1]

9.6.3.2 Positive alarm sequence in accordance with 55.2.3.4 of *NFPA 5000* shall be permitted. [**5000:**16.3.4.3.2]

9.6.3.3 Occupant notification shall be by means of voice announcements in accordance with 55.2.3.9 of *NFPA 5000*, initiated by the person in the constantly attended receiving station. [**5000:**16.3.4.3.3]

9.6.3.4 Occupant notification shall be by means of visible signals in accordance with 55.2.3.5 of *NFPA 5000*, initiated by the person in the constantly attended receiving station, unless otherwise permitted by 9.6.3.5. [**5000:**16.3.4.3.4]

9.6.3.5* Where the occupant load of a single room or space exceeds 1000, visible signals shall not be required in the assembly seating area, or the floor area used for the contest, performance, or entertainment where the occupancy load exceeds 1,000 and an approved alternative visible means of occupant notification is provided *(see 55.2.3.5.5 of NFPA 5000)*. *[***5000:***16.3.4.3.5]*

9.6.3.6 The announcement shall be permitted to be made via voice communication or public address system in accordance with 55.2.3.9.2 of *NFPA 5000*. [**5000:**16.3.4.3.6]

9.6.3.7 Where the authority having jurisdiction determines that it is impractical to have a constantly attended receiving station, both of the following shall be provided:

(1) Automatically transmitted evacuation or relocation instructions shall be provided in accordance with *NFPA 72*.
(2) The system shall be monitored by a supervising station in accordance with *NFPA 72*.

[**5000:**16.3.4.3.7]

Chapter 10 Services

10.1 Electrical Systems. Electrical wiring and equipment shall be in accordance with *NFPA 70* unless such installations are approved existing installations, which shall be permitted to be continued in service. [***101*:**9.1.2]

10.2 Heating, Ventilating, and Air-Conditioning. [***101*:**9.2]

10.2.1 Air-Conditioning, Heating, Ventilating Ductwork, and Related Equipment. Air-conditioning, heating, ventilating ductwork, and related equipment shall be in accordance with NFPA 90A or NFPA 90B as applicable, unless such installations are approved existing installations, which shall be permitted to be continued in service. [***101*:**9.2.1]

10.2.2 Ventilating or Heat-Producing Equipment. Ventilating or heat-producing equipment shall be in accordance with NFPA 91, NFPA 211, NFPA 31, NFPA 54, or *NFPA 70* as applicable, unless such installations are approved existing installations, which shall be permitted to be continued in service. [***101*:**9.2.2]

10.3 Fired Heaters. [***101*:**11.9.5.1]

10.3.1 Only labeled heating devices shall be used. [***101*:**11.9.5.1.1]

10.3.2 Fuel-fired heaters and their installation shall be approved by the authority having jurisdiction. [***101*:**11.9.5.1.2]

10.4 Electric Heaters. [***101*:**11.9.5.2]

10.4.1 Only labeled heaters shall be permitted. [***101*:**11.9.5.2.1]

10.4.2 Electric heaters, their placement, and their installation shall be approved by the authority having jurisdiction. [***101*:**11.9.5.2.2]

10.4.3 Heaters shall be connected to electricity by electric cable that is suitable for outside use and is of sufficient size to handle the electrical load. [***101*:**11.9.5.2.3]

Annex A Explanatory Material

Annex A is not a part of the requirements of this NFPA document but is included for informational purposes only. This annex contains explanatory material, numbered to correspond with the applicable text paragraphs.

A.3.2.1 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

A.3.2.2 Authority Having Jurisdiction (AHJ). The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A.3.2.3 Code. The decision to designate a standard as a "code" is based on such factors as the size and scope of the document, its intended use and form of adoption, and whether it contains substantial enforcement and administrative provisions.

A.3.2.5 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A.3.3.2 Air-Supported Structure. A cable-restrained air-supported structure is one in which the uplift is resisted by cables or webbing that is anchored by various methods to the membrane or that might be an integral part of the membrane. An air-supported structure is not a tensioned-membrane structure. [**5000:** A.3.3.631.4]

A.3.3.3 Assembly Occupancy. Assembly occupancies might include the following:

(1) Armories
(2) Assembly halls
(3) Auditoriums
(4) Bowling lanes
(5) Club rooms
(6) College and university classrooms, 50 persons and over
(7) Conference rooms
(8) Courtrooms
(9) Dance halls
(10) Drinking establishments
(11) Exhibition halls
(12) Gymnasiums
(13) Libraries
(14) Mortuary chapels
(15) Motion picture theaters
(16) Museums
(17) Passenger stations and terminals of air, surface, underground, and marine public transportation facilities
(18) Places of religious worship
(19) Pool rooms
(20) Recreation piers
(21) Restaurants
(22) Skating rinks
(23) Special amusement buildings, regardless of occupant load
(24) Theaters

[**5000:** A.3.3.445.2]

Assembly occupancies are characterized by the presence or potential presence of crowds with attendant panic hazard in case of fire or other emergency. They are generally open or occasionally open to the public, and the occupants, who are present voluntarily, are not ordinarily subject to discipline or control. Such buildings are ordinarily occupied by able-bodied persons and are not used for sleeping purposes. Special conference rooms, snack areas, and other areas incidental to, and under the control of, the management of other occupancies, such as offices, fall under the 50-person limitation. [**5000:** A.3.3.445.2]

Restaurants and drinking establishments with an occupant load of fewer than 50 persons should be classified as mercantile occupancies. [**5000:** A.3.3.445.2]

A.3.3.5 Exit. Exits include exterior exit doors, exit passageways, horizontal exits, exit stairs, and exit ramps. In the case of a stairway, the exit includes the following:

(1) Stair enclosure

(2) Door to the stair enclosure
(3) Stairs and landings inside the enclosure
(4) Door from the stair enclosure to the outside or to the level of exit discharge
(5) Any exit passageway and its associated doors, if such are provided, so as to discharge the stair directly to the outside. In the case of a door leading directly from the street floor to the street or open air, the exit comprises only the door.

[**5000:** A.3.3.205]

Doors of small individual rooms, as in hotels, while constituting exit access from the room, are not referred to as exits, except where they lead directly to the outside of the building from the street floor. [**5000:** A.3.3.205]

A.3.3.10 Grandstand. Where the term *grandstand* is preceded by an adjective denoting a material, it refers to a grandstand the essential members of which, exclusive of seating, are of the material designated. [**5000:** A.3.3.291]

A.3.3.12 Means of Egress. A means of egress comprises the vertical and horizontal travel and includes intervening room spaces, doorways, hallways, corridors, passageways, balconies, ramps, stairs, elevators, enclosures, lobbies, escalators, horizontal exits, courts, and yards. [**5000:** A.3.3.411]

A.3.3.20 Tent. A tent might also include a temporary tensioned-membrane structure. [**5000:** A.3.3.647]

A.7.3.2 UL Subject 1588, *Outline of Investigation for Roof and Gutter De-Icing Cable Units*, is used to list de-icing and snow-melting equipment intended to be installed in accordance with *NFPA 70*. [**5000:** A.32.2.3.2]

A.7.4.1 See *ASCE Guide for Tensioned Fabric Structures*. [**5000:** A.32.2.4.1]

A.7.5.3 UL Subject 1588, *Outline of Investigation for Roof and Gutter De-Icing Cable Units,* is used to list de-icing and snow-melting equipment intended to be installed in accordance with *NFPA 70*. [**5000:** A.32.2.5.3]

A.9.2.2 NFPA 58 permits portable butane-fueled appliances in restaurants and in attended commercial food catering operations where fueled by not in excess of two 10 oz (0.28 kg) LP-Gas capacity, nonrefillable butane containers having a water capacity not in excess of 1.08 lb (0.4 kg) per container. Containers are required to be directly connected to the appliance, and manifolding of containers is not permitted. Storage of cylinders is also limited to 24 containers, with an additional 24 permitted where protected by a 2-hour fire resistance–rated barrier. [***101*:** A.8.7.3.2]

A.9.3 Securely supported altar candles in churches that are well separated from any combustible material are permitted. On the other hand, lighted candles carried by children wearing cotton robes present a hazard too great to be permitted. There are many other situations of intermediate hazard where the authority having jurisdiction will have to exercise judgment. [***101*:** A.12.7.3(3)(a)]

A.9.6.2.3 The intent is to require detectors only in nonsprinklered hazardous areas that are unoccupied. When the building is occupied, the detectors in the unoccupied, unsprinklered hazardous areas will initiate occupant notification. If the building is unoccupied, the fire in the nonsprinklered hazardous area is not a life safety issue, and the detectors, upon activation, are not required to notify anyone. The signal from a detector is permitted to be sent to a control panel in an area that is occupied when the building is occupied, but that is unoccupied when the building is unoccupied, without the need for central station monitoring or the equivalent. [**5000:** A.16.3.4.2.3]

A.9.6.3.5 Examples of devices that might be used to provide alternative visible means include scoreboards, message boards, and other electronic devices. [**5000:** A.16.3.4.3.5]

Annex B Informational References

B.1 Referenced Publications. The documents or portions thereof listed in this annex are referenced within the informational sections of this standard and are not part of the requirements of this document unless also listed in Chapter 2 for other reasons.

NFPA®105

Standard for

Smoke Door Assemblies and Other Opening Protectives

2016 Edition

This edition of NFPA 105, *Standard for Smoke Door Assemblies and Other Opening Protectives*, was prepared by the Technical Committee on Fire Doors and Windows. It was issued by the Standards Council on May 26, 2015, with an effective date of June 15, 2015, and supersedes all previous editions.

This edition of NFPA 105 was approved as an American National Standard on June 15, 2015.

Origin and Development of NFPA 105

This publication is the result of a multiyear project by the Technical Committee on Fire Doors and Windows and is based on the acknowledgment that smoke is the principal killer in destructive fires. Historically, fire doors have been permitted to have such clearances and deflections as would permit the passage of relatively great quantities of smoke. Those fire doors, when properly installed, have proven to be adequate barriers against the passage of fire, but improvement was needed to protect against the passage of smoke.

The first (1985) edition of NFPA 105 was a recommended practice and introduced parameters for door performance that would limit smoke spread through a door opening.

The third (1993) edition incorporated new information recognizing that smoke control doors in buildings protected by automatic sprinklers would have substantially lower pressures created by a potential fire.

The 1999 edition included modifications to address the pressure differentials caused by stack effect in elevator hoistways.

The 2003 edition incorporated editorial and formatting updates to comply with the *Manual of Style for NFPA Technical Committee Documents*, as well as formatting requirements for converting from a recommended practice to a standard. The 2003 edition also included significant modifications to Chapter 4 on installation and testing requirements and to Chapter 5 on maintenance requirements. Annex A contained a considerable amount of new and updated information.

The 2007 edition expanded the scope of the document to include smoke dampers. The title of the document was revised, and new chapters on the installation, inspection, testing, and maintenance of smoke dampers were provided. Other technical changes addressed the retention of maintenance records for smoke door assemblies.

The 2010 edition included modifications to smoke damper inspection and testing requirements. The title of the document was also revised.

The 2013 edition added references to NFPA 80, *Standard for Fire Doors and Other Opening Protectives*, for the inspection and testing requirements of smoke door assemblies. Other technical changes addressed the inspection and testing of smoke dampers and labeling of smoke damper access panels.

The 2016 edition of NFPA 105 represents a significant expansion and update of the document. For consistency with NFPA 80 and to allow for a more user-friendly document, a new chapter, Chapter 6, Swinging Doors, contains provisions specific to the installation of side-hinged and pivoted swinging smoke door assemblies. Provisions for smoke dampers have been moved to a new Chapter 7, Installation, Testing, and Maintenance of Smoke Dampers. Additional chapters will be added in future editions of NFPA 105 to address requirements for other specific types of smoke doors and opening protectives. Also for consistency with NFPA 80, the inspection, testing, and maintenance provisions for smoke door assemblies in Chapter 5 have been expanded to address multiple types of smoke doors as well as three types of testing — operational, acceptance, and periodic. A new chapter,

NFPA and National Fire Protection Association are registered trademarks of the National Fire Protection Association, Quincy, Massachusetts 02169.

Chapter 8, Smoke Protective Curtain Assemblies, addresses the installation, inspection, testing, and maintenance of smoke-protective curtain assemblies used to protect vertical openings. Significant technical changes have also been added regarding the acceptance and periodic testing of smoke dampers. Finally, new definitions for *qualified person* and *smoke protective curtain assembly* have been added along with updates to referenced publications to maintain the requirements and application of NFPA 105 current with industry trends and practices.

This list represents the membership at the time the Committee was balloted on the final text of this edition. Since that time, changes in the membership may have occurred. A key to classifications is found at the back of the document.

NOTE: Membership on a committee shall not in and of itself constitute an endorsement of the Association or any document developed by the committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on the installation and maintenance of fire doors, windows, shutters, and other equipment used to restrict the spread of fire, including arrangements for automatic operation in case of fire. This includes installation to protect buildings against external fire and to restrict the spread of fire within buildings. Vault and record room doors are covered by the Technical Committee on Record Protection.

NFPA 105

Standard for

Smoke Door Assemblies and Other Opening Protectives

2016 Edition

IMPORTANT NOTE: This NFPA document is made available for use subject to important notices and legal disclaimers. These notices and disclaimers appear in all publications containing this document and may be found under the heading "Important Notices and Disclaimers Concerning NFPA Documents." They can also be obtained on request from NFPA or viewed at www.nfpa.org/disclaimers.

UPDATES, ALERTS, AND FUTURE EDITIONS: New editions of NFPA codes, standards, recommended practices, and guides (i.e., NFPA Standards) are released on scheduled revision cycles. This edition may be superseded by a later one, or it may be amended outside of its scheduled revision cycle through the issuance of Tentative Interim Amendments (TIAs). An official NFPA Standard at any point in time consists of the current edition of the document, together with any TIAs and Errata in effect. To verify that this document is the current edition or to determine if it has been amended by any TIAs or Errata, please consult the National Fire Codes® Subscription Service or visit the Document Information (DocInfo) pages on the NFPA website at www.nfpa.org/docinfo. In addition to TIAs and Errata, the DocInfo pages also include the option to sign up for Alerts for each document and to be involved in the development of the next edition.

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates that explanatory material on the paragraph can be found in Annex A.

A reference in brackets [ ] following a section or paragraph indicates material that has been extracted from another NFPA document. As an aid to the user, the complete title and edition of the source documents for extracts in mandatory sections of the document are given in Chapter 2 and those for extracts in informational sections are given in Annex C. Extracted text may be edited for consistency and style and may include the revision of internal paragraph references and other references as appropriate. Requests for interpretations or revisions of extracted text shall be sent to the technical committee responsible for the source document.

Information on referenced publications can be found in Chapter 2 and Annex C.

Chapter 1 Administration

1.1 Scope. This standard shall prescribe minimum requirements for smoke door assemblies for use in providing safety to life and protection of property from smoke.

1.2* Purpose. The purpose of this standard shall be to provide a means to restrict the movement of smoke through door assemblies in order to maintain a tenable environment.

1.3* Application. This standard shall regulate the installation, maintenance, and testing of smoke door assemblies.

1.3.1* This standard shall regulate smoke door assemblies that are intended to restrict the passage of smoke at temperatures up to 400°F (204°C).

1.3.2* This standard shall not regulate elevator hoistway doors.

1.4 Retroactivity. This standard is based on product and engineering practices recognized as acceptable at the date of issue. Therefore, the provisions of this standard are not intended to be applied retroactively to installations that were in compliance at the time of installation.

1.5 Equivalency.

1.5.1 This standard shall not prohibit the development of new, modified, or improved devices that meet the intent of these requirements. It shall be the responsibility of the manufacturer to furnish the information necessary to update the requirements pertaining to such new and improved devices.

1.5.2 For devices not described in this standard, the authority having jurisdiction (AHJ) shall request descriptive information from manufacturers that is provided by a testing laboratory concerning acceptable methods for satisfactory field installation based on fire tests and engineering studies for operation and maintenance considerations, where applicable.

Chapter 2 Referenced Publications

2.1 General. The documents or portions thereof listed in this chapter are referenced within this standard and shall be considered part of the requirements of this document.

2.2 NFPA Publications. National Fire Protection Association, 1 Batterymarch Park, Quincy, MA 02169-7471.

NFPA 72®, National Fire Alarm and Signaling Code, 2016 edition.

Chapter 3 Definitions

3.1 General. The definitions contained in this chapter shall apply to the terms used in this standard. Where terms are not defined in this chapter or within another chapter, they shall be defined using their ordinarily accepted meanings within the context in which they are used. *Merriam-Webster's Collegiate Dictionary*, 11th edition, shall be the source for the ordinarily accepted meaning.

3.2 NFPA Official Definitions.

3.2.1* Approved. Acceptable to the authority having jurisdiction.

3.2.2* Authority Having Jurisdiction (AHJ). An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

3.2.3 Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

3.2.4* Listed. Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

3.2.5 Shall. Indicates a mandatory requirement.

3.2.6 Should. Indicates a recommendation or that which is advised but not required.

3.2.7 Standard. An NFPA Standard, the main text of which contains only mandatory provisions using the word "shall" to indicate requirements and that is in a form generally suitable for mandatory reference by another standard or code or for adoption into law. Nonmandatory provisions are not to be considered a part of the requirements of a standard and shall be located in an appendix, annex, footnote, informational note, or other means as permitted in the NFPA Manuals of Style. When used in a generic sense, such as in the phrase "standards development process" or "standards development activities," the term "standards" includes all NFPA Standards, including Codes, Standards, Recommended Practices, and Guides.

3.3 General Definitions.

3.3.1 Qualified Person. A person who, by possession of a recognized degree, certificate, professional standing, or skill, and who, by knowledge, training, and experience, has demonstrated the ability to deal with the subject matter, the work, or the project.

3.3.2 Smoke Damper. A device within an air distribution system to control the movement of smoke.

3.3.2.1 ***Combination Fire/Smoke Damper.*** A device that meets both the fire damper and smoke damper requirements.

3.3.3 Smoke Door. The door component of a smoke door assembly.

3.3.4 Smoke Protective Curtain Assembly. Assembly typically consisting of a fabric curtain, bottom bar, guides, coil, operating and closing system.

3.3.5 Smoke Door Assembly. Any combination of a door, frame, hardware, and any other accessories that together restrict smoke movement through door openings by limiting the amount of air that can pass through the assembly.

3.3.6 Temperature.

3.3.6.1 ***Ambient Temperature.*** An assumed air temperature at the exposed face of the door at or near 75°F (24°C).

3.3.6.2* ***Elevated Temperature.*** An assumed air temperature at the exposed face of the door in excess of ambient temperature.

3.3.7* Tenable Environment. An environment in which smoke and heat are limited or otherwise restricted to maintain the impact on occupants to a level that is not life threatening. [**92**, 2015]

Chapter 4 General Requirements

4.1 General. This chapter shall cover the requirements for testing of smoke door assemblies.

4.2 Test Specimen.

4.2.1 The size of the door to be tested shall be 3 ft × 7 ft (0.9 m × 2.1 m) for a single side-hinged swinging door, and 6 ft × 7 ft (1.8 m × 2.1 m) for a pair of side-hinged swinging doors and all other doors, or shall be representative of the full range of smoke door production for that type of construction as determined by the testing laboratory.

4.2.2 For the air leakage test, fire door assemblies shall be installed in accordance with NFPA 80.

4.2.2.1 Clearances for doors without a fire protection rating shall be in accordance with the manufacturer's specifications.

4.2.3* Doors intended for installation in frames containing transoms, side lights, or side panels shall be tested with such frames.

4.2.4 Specimens of door assemblies shall be tested as they are intended to be installed.

4.3 Air Leakage Test.

4.3.1* Smoke door assemblies shall have an air leakage rating not greater than 3 $ft^3/min/ft^2$ (0.9 $m^3/min/m^2$) of door opening when tested in accordance with ANSI/UL 1784, *Air Leakage Tests of Door Assemblies*.

4.3.2* Smoke door assemblies intended for installation where pressurization is provided to control smoke movement shall not have an artificial bottom seal installed during the test.

4.3.3* Where data exists to verify that tests at ambient temperature result in a higher leakage rate, additional tests at elevated temperature shall not be required.

4.3.4* The test shall be required to be performed only at a pressure differential of 0.1, 0.2, or 0.3 ± 0.005 in. of water (25, 50, or 75 ± 1.25 Pa).

4.4* Labeling. Smoke door assemblies shall bear an "S" label indicating a maximum air leakage rate of 3 $ft^3/min/ft^2$ (0.9 $m^3/min/m^2$) and the tested pressure differential of 0.1, 0.2, or 0.3 in. of water (25, 50, or 75 Pa).

4.5 Installation.

4.5.1 Smoke doors shall be self-closing or automatic closing in accordance with NFPA 80.

4.5.2 Automatic closing smoke door assemblies shall be activated by smoke detection installed in accordance with *NFPA 72*.

4.5.3 Devices for the release of smoke doors shall be permitted to be part of an overall system, such as a fire alarm or an automatic extinguishing system, that shall release the door and shall be installed and tested in accordance with *NFPA 72*.

4.5.4 The opening between the bottom edge of the smoke door and the sill when the door is in the closed position shall not be required to be provided with a means to seal the opening.

4.5.4.1 Smoke door assemblies installed where pressurization is provided to restrict smoke movement shall be required to have a bottom seal.

4.5.5 Louvers shall not be installed in smoke door assemblies unless otherwise tested and listed.

Chapter 5 Inspection, Testing, and Maintenance of Smoke Door Assemblies

5.1 General. This chapter covers the inspection, testing, and maintenance of smoke door assemblies.

5.1.1 Application.

5.1.1.1 This chapter shall cover the inspection, testing, and maintenance of smoke door assemblies.

5.1.1.2 The requirements of this chapter shall apply to new and existing installations.

5.1.2 Removal of Smoke Doors. Where a smoke door no longer functions as an opening or is removed and not replaced, the opening shall be filled with construction to maintain the smoke partition or smoke barrier properties of the wall.

5.1.3 Operability.

5.1.3.1* Smoke doors shall be operable at all times.

5.1.3.2 Smoke doors shall be kept closed or arranged for automatic closing, unless otherwise permitted.

5.1.3.3 Where required, the doors shall be positively latched.

5.1.4 Replacement. Where it is necessary to replace all or part of a smoke door assembly, replacement components shall be installed to meet the requirements of this standard and the manufacturer's instructions.

5.1.5 Field Modifications.

5.1.5.1 Field modifications of fire-rated smoke door assemblies shall be made in accordance with NFPA 80.

5.1.5.2* Field modifications of smoke door assemblies without fire ratings shall be permitted to be made, provided the modifications are performed in accordance with the applicable requirements of this standard.

5.1.5.3 Upon completion of field modification work, smoke door assemblies shall be inspected in accordance with Section 5.2.

5.2 Inspections and Testing.

5.2.1 Upon installation, smoke door assemblies shall be inspected and tested in accordance with the following:

(1) Fire-rated smoke door assemblies shall be inspected and tested in accordance with this standard and also in accordance with Chapter 5 of NFPA 80.
(2) Door assemblies without fire ratings shall be inspected in accordance with the requirements of this standard.
(3) Inspections of smoke door assemblies without fire ratings shall be permitted to be performed at the same time as inspections for door assemblies subject to inspection under NFPA 80.
(4) All functional tests shall be conducted after the building's mechanical ventilation system has been balanced and is operating.
(5) All functional tests shall be conducted after the closing mechanism has been adjusted for the applicable maximum allowable opening force.

5.2.2* A record of all inspections and testing shall be signed by the inspector and kept for inspection by the AHJ.

5.2.2.1 Records of the acceptance tests shall be retained for the life of the assembly.

5.2.2.2* Unless a longer period is required by NFPA 80, records shall be retained for a period of at least 3 years.

5.2.2.3* The records shall be on a medium that will survive the retention period. Paper or electronic media shall be permitted. [***72:***14.6.2.3]

5.2.2.4 A record of all inspections and testing shall be provided that includes, but is not limited to, the following information:

(1) Date of inspection
(2) Name of facility
(3) Address of facility
(4) Name of person(s) performing inspections and testing
(5) Company name and address of inspecting company
(6) Signature of inspector of record
(7) Individual record of each inspected and tested [smoke] door assembly
(8)* Opening identifier and location of each inspected and tested [smoke] door assembly
(9)* Type and description of each inspected and tested [smoke] door assembly
(10)* Verification of visual inspection and functional operation
(11) Listing of deficiencies in accordance with 5.2.4

[**80:**5.2.2.4]

5.2.3 Maintenance Records.

5.2.3.1 Upon completion of maintenance, smoke door assemblies shall be inspected and tested in accordance with 5.2.4

5.2.3.2 A record of these inspections and testing shall be made in accordance with 5.2.2.

5.2.3.3 A record of maintenance performed on existing smoke door assemblies shall be provided that includes, but is not limited to, the following information:

(1) Date of maintenance
(2) Name of facility
(3) Address of facility
(4) Name of person(s) performing maintenance
(5) Company name and address of maintenance personnel
(6) Signature of maintenance personnel performing the work
(7) Individual listings of each maintained smoke door assembly
(8) Opening identifier and location of each repaired smoke door assembly
(9) Type and description of each repaired smoke door assembly
(10) Description or listing of the work performed on each smoke door assembly

5.2.4* Acceptance Testing. Acceptance testing of smoke door assemblies shall be performed by a qualified person with knowledge and understanding of the operating components of the type of assembly subject to testing.

5.2.4.1* Before testing, a visual inspection shall be performed to identify any damaged or missing parts that can create a hazard during testing or affect operation or resetting.

5.2.4.2 Acceptance testing shall include the closing of the door by all means.

5.2.4.2.1 Acceptance testing shall be conducted after the building's mechanical ventilation system has been balanced, in accordance with 5.2.1.

5.2.4.2.2 Acceptance testing shall be conducted after the closing mechanism has been adjusted for the applicable maximum allowable opening force.

5.2.4.3 A record of these inspections and testing shall be made in accordance with 5.2.2.

5.2.4.4 Swinging Smoke Door Assemblies.

5.2.4.4.1 Smoke door assemblies shall be visually inspected from both sides to assess the overall condition of the assembly.

5.2.4.4.2 As a minimum, the following items shall be verified:

(1) Labels on fire-rated smoke door assemblies are clearly visible and legible and bear the "S" label marking.
(2) Door leaves without fire protection ratings comply with 6.3.1.
(3) Door frames comply with 6.3.2.
(4) Gasketing along the vertical edges of the door and across the top of the door and, where required, at meeting edges of pairs of doors forms a continuous seal that is not cut, notched, or otherwise modified to accommodate other hardware items.
(5) Gasketing materials, where required, are intact and close the gaps between the door and frame to seal the door opening against the passage of smoke.
(6) Doors installed in pressurized applications have a bottom seal, where required.
(7) Doors equipped with bottom seals that automatically project to fully seal the gap under the door in the closed position do not interfere with the swinging of the door when retracted or the closing of the door when projected.
(8) No open holes or breaks exist in the surfaces of either the door or the frame.
(9) Glazing, vision light frames, and glazing beads are intact and securely fastened in place, if so equipped.
(10) Glazing materials and vision light kits comply with Sections 6.5 and 6.6.
(11) Glazing materials, vision light kits, and glazing beads are continuously sealed.
(12) The door, frame, hinges, and other hardware are secured, aligned, and in working order with no visible signs of damage.
(13) No parts are missing or broken.
(14) Door clearances do not exceed dimensions listed in 6.3.3 when measured on the pull side of the door(s).
(15) The self-closing device is operational; that is, the active door completely closes when operated from the full open position.
(16) If a coordinator is installed, the inactive leaf closes before the active leaf.
(17) Where positive latching is required, latching hardware operates and secures the door when the door is in the closed position.
(18) Where door leaves, other than doors arranged for automatic closing, are permitted to be held open with friction door holder devices, the door holder devices comply with 6.3.6.6.

5.2.4.5 Horizontally Sliding, Vertically Sliding, and Rolling Doors.

5.2.4.5.1 Smoke door assemblies shall be visually inspected from both sides to assess the overall condition of the door assembly.

5.2.4.5.2 The following items shall be verified:

(1) Labels are clearly visible and legible.
(2) No open holes or breaks exist in surfaces of either the door or the frame.
(3) Slats, endlocks, bottom bar, guide assembly, curtain entry, hood, and flame baffle are correctly installed and intact for rolling steel fire doors.
(4) Gasketing along the perimeter of the door forms a continuous seal that is not cut, notched, or otherwise modified.
(5) Glazing, vision light frames, and glazing beads are intact and securely fastened in place, if so equipped.
(6) Curtain, barrel, and guides are aligned, level, plumb, and true for rolling steel fire doors.
(7) Expansion clearance is maintained in accordance with manufacturer's listing.
(8) Drop release arms and weights are not blocked or wedged.
(9) Mounting and assembly bolts are intact and secured.
(10) Attachments to jambs are with bolts, expansion anchors, or as otherwise required by the listing.
(11) Smoke detectors, if equipped, are installed and operational.
(12) No parts are missing or broken.

(13)* Fusible links, if so equipped, are in the location; chain/cable, s-hooks, eyes, and so forth, are in good condition; the cable or chain is not kinked, pinched, twisted, or inflexible; and links are not painted or coated with dust or grease.
(14) Auxiliary hardware items that interfere or prohibit operation are not installed on the door or frame.
(15) No field modifications to the door assembly that void the label have been performed.
(16) Doors have an average closing speed of not less than 6 in./sec (152 mm/sec) or more than 24 in./sec (610 mm/sec).

5.2.5 Periodic Inspection and Testing.

5.2.5.1 Periodic inspection and testing shall be performed not less than annually.

5.2.5.2 As a minimum, the provisions of 5.2.4 shall be included in the periodic inspection and testing procedure.

5.2.5.3 Inspection shall include an operational test for automatic-closing doors to verify that the assembly will close under fire conditions.

5.2.5.4 The assembly shall be reset after each test.

5.2.5.5 Resetting of the release mechanism shall be done in accordance with the manufacturer's instructions.

5.2.5.6 Hardware and gaskets shall be inspected annually, and any parts found to be damaged or inoperative shall be replaced without delay.

5.2.5.7 Tin-clad and Kalamein doors shall be inspected regularly for dry rot.

5.3* Performance-Based Option.

5.3.1 As an alternative means of compliance with 5.2.5, subject to the AHJ, smoke door assemblies shall be permitted to be inspected, tested, and maintained under a written performance-based program.

5.3.2 Goals established under a performance-based program shall provide assurance that the smoke door assembly will perform its intended function when exposed to fire conditions.

5.3.3 The technical justification for inspection, testing, and maintenance intervals shall be documented in writing.

5.3.4 The performance-based option shall include historical data acceptable to the AHJ.

5.4 Maintenance.

5.4.1* Repairs shall be made, and defects that could interfere with operation shall be corrected without delay.

5.4.2 Fire-rated smoke door assemblies shall also be maintained in accordance with NFPA 80.

5.4.3 Damaged glazing material shall be replaced in accordance with the applicable codes.

5.4.4 Replacement glazing material shall be installed in accordance with its individual listing, where required, and the manufacturer’s listing.

5.4.5 Where holes are left in a door or frame due to changes or removal of hardware or plant-ons, the holes shall be sealed to resist the passage of smoke at ambient and elevated temperatures up to 400°F (204°C).

5.4.6 Where a smoke door, frame, or any part of its appurtenances is damaged to the extent that it could impair the door assembly's proper emergency function, the following actions shall be performed:

(1) The door, frame, door assembly, or any parts of its appurtenances shall be replaced with parts obtained from the original manufacturer.
(2) The door shall be tested to ensure emergency operation and closing upon completion of the repairs, in accordance with 5.2.3.

5.4.7 If repairs cannot be made with parts obtained from the original manufacturer or retrofitted, the door, the door assembly, or appurtenances shall be replaced.

5.5 Prevention of Door Blockage.

5.5.1 Door openings and the surrounding areas shall be kept clear of anything that could obstruct or interfere with the free operation and full closure of the door.

5.5.2 Blocking or wedging of doors in the open position shall be prohibited.

5.6 Maintenance of Closing Mechanisms.

5.6.1 Self-closing and automatic closing devices shall be kept in working condition at all times.

5.6.2 Care shall be taken to prevent paint accumulation on any movable parts such as, but not limited to, hinges, pivots, closer arms, and latching hardware.

Chapter 6 Swinging Doors

6.1* General. This chapter shall cover the installation of side-hinged and side-pivoted swinging smoke door assemblies.

6.2 Swinging Doors with Fire Protection Ratings. Fire door assemblies that are intended for use as smoke door assemblies shall also comply with NFPA 80.

6.3* Swinging Doors Without Fire Protection Ratings. Doors without fire protection ratings shall be permitted to be used as smoke door assemblies in door openings not required to be protected by fire doors.

6.3.1* Doors. Non-fire-rated door leaves shall be of a design that resists the passage of smoke.

6.3.1.1* Vertical edges of new composite and wood door leaves shall be square edged or beveled.

6.3.1.2 Doors installed in pairs shall be beveled or have astragals or rabbets at meeting edges.

6.3.1.3 Doors shall be flush mounted in door frames.

6.3.1.4 Dutch doors shall be permitted to be used, provided they comply with the following:

(1) Both the upper leaf and the lower leaf are equipped with a latching device.
(2) The meeting edges of the upper and lower leaves are equipped with an astragal or a rabbet.

6.3.1.5 Louvers and transfer grilles shall not be permitted in doors.

6.3.2 Door Frames. Door frames shall be labeled or comply with 6.3.2.1.

6.3.2.1 Where permitted by other standards, door frames shall be of steel construction or shall be of other designs that have been tested and reported by a nationally recognized testing agency in accordance with NFPA 252; ANSI/UL 10B, *Standard for Fire Tests of Door Assemblies*; or ANSI/UL 10C, *Standard for Positive Pressure Fire Tests of Door Assemblies*.

6.3.2.2* Door frames with terminated stops shall be permitted, provided the lowest portion of the terminated stops is not greater than 6 in. (152 mm) above the bottom of the frame.

6.3.2.3 Supporting Construction. Wall openings shall be constructed to readily accept the door frames.

6.3.2.4 The door frames shall be considered to be non–load bearing.

6.3.2.5 Frames shall be securely anchored to the wall construction.

6.3.3* Clearances. Doors in smoke partitions shall have clearances in accordance with NFPA 80.

6.3.3.1* Doors in smoke barriers shall close the opening, leaving only the minimum clearance necessary for proper operation. The clearance under the bottom of a new door shall be a maximum of ¾ in. (19 mm).

6.3.3.2 The maximum clearance between the bottom of side-hinged or -pivoted swinging smoke doors and the finished floor shall be not greater than ¾ in. (19 mm), unless otherwise permitted.

6.3.3.3 Where the bottom of the door is more than 38 in. (965 mm) above the finished floor, the maximum clearance under the door shall not exceed ⅜ in. (10 mm).

6.3.4* Latching Hardware. Where required, smoke doors without fire protection rating shall be provided with hardware that provides positive latching.

6.3.5 Operation of Doors. Doors shall be arranged to be either self-closing or automatic closing, where required, unless otherwise exempted.

6.3.5.1* Self-Closing. Self-closing doors shall swing easily and freely and shall be equipped with a closing device that closes, the door, causing it to latch, each time the door closes.

6.3.5.2 The closing mechanism shall not have a hold-open feature.

6.3.5.3 Automatic Closing. Automatic-closing doors shall be permitted to close automatically by means of the installation of a closing device and the following:

(1) Upon release of the hold-open mechanism, the leaf becomes self-closing.
(2) The release device is designed so that the leaf instantly releases manually and, upon release, becomes self-closing, or the leaf can be readily closed.
(3) The automatic releasing mechanism or medium is activated by the operation of approved smoke detectors installed in accordance with the requirements for smoke detectors for door leaf release service in *NFPA 72*.
(4) Upon loss of power to the hold-open device, the hold-open mechanism is released and the door leaf becomes self-closing.
(5) The release by means of smoke detection of one door leaf in a smokeproof enclosure or a stair enclosure results in closing all door leaves serving the enclosure.
(6) Where required, doors properly latch upon closing.

6.3.5.4 Power-Operated Doors. Power-operated doors shall be equipped with a releasing device that automatically disconnects the power operator at the time of fire, allowing a self-closing or automatic device to close the door regardless of power failure or manual operation, provided all the following criteria are met:

(1) The door is equipped with a means for keeping the door closed that is acceptable to the AHJ.
(2) The device used is capable of keeping the door fully closed if a force of 5 lbf (22 N) is applied to the latch edge of swinging doors, whether or not power is applied.

6.3.6* Builders Hardware

6.3.6.1 Conventional Hinges. Conventional hinges used on doors with closing devices shall have ball bearings or anti-friction bearings and meet the requirements of ANSI/BHMA A156.1, *Standard for Butts and Hinges*.

6.3.6.1.1 Hinges shall be sized in thickness, height, and width in accordance with the hinge manufacturer's recommended guidelines.

6.3.6.1.2 Hinges shall have brass/bronze or steel base materials or be stainless steel.

6.3.6.1.3 Doors up to 60 in. (1.52 m) in height shall be provided with two hinges and an additional hinge for each additional 30 in. (0.76 m) of door height or fraction thereof.

6.3.6.1.4 The distance between hinges shall be permitted to exceed 30 in. (0.76 m).

6.3.6.1.5 Where spring hinges are used, at least two shall be provided.

6.3.6.2 Pivots. Pivots shall be in compliance with NFPA 80.

6.3.6.3 Continuous Hinges. Continuous hinges shall be in compliance with NFPA 80.

6.3.6.4* Locks and Latches. Locking and latching shall comply with NFPA 80.

6.3.6.4.1 Where panic hardware is utilized, the latching device shall not be permitted to be mechanically held in the retracted position.

6.3.6.4.2 Latching arrangements that do not provide positive latching in the normal mode shall be permitted to be used provided that, in a fire emergency, the door becomes positively latched by means of an automatic fail-safe device that is activated by an automatic fire detector. [**80:**6.4.4.3.3]

6.3.6.4.3 Strike plates for locks and latches on pairs of doors shall not have extended lips that prevent astragals from sealing the gap at the meeting edges of the doors.

6.3.6.5 Door-Closing Devices. Door-closing devices, other than spring hinges, shall meet the requirements of ANSI/BHMA A156.4, *Door Controls — Closers, Grade 1*.

6.3.6.5.1 Where non-fire-rated doors are permitted to be held open, the door closing device shall be permitted to have an integral friction hold-open feature that permits the door to be closed when pulled or pushed.

6.3.6.5.2 Doors arranged for automatic closing shall have a closing device that meets the requirements of 6.3.5.3.

6.3.6.6 Door Holder/Release Devices.

6.3.6.6.1 Door holder/release devices for automatic-closing doors shall be installed in accordance with the manufacturer's instructions and in conformance with the individual manufacturer's published listings.

6.3.6.6.2 Where required for non-fire-rated smoke doors without door closers, only door holder devices that release when pushed or pulled shall be permitted.

6.3.6.7* Protection Plates. Doors without fire protection rating are permitted to have non-rated, factory- or field-applied protection plates of unlimited size, unless otherwise restricted by the door or protection plate manufacturers' specifications.

6.3.6.8* Attaching Hardware to Doors and Frames. Hardware items shall be attached to doors and frames in accordance with NFPA 80.

6.4 Vision Panels in Doors.

6.4.1 Glazing materials shall be capable of resisting the passage of smoke.

6.4.2 The perimeter of the glazing material and vision panel frames shall be sealed to resist the passage of smoke at temperatures up to 400°F (204°C).

6.4.3 Vision panels in smoke doors required to have a fire protection rating shall comply with NFPA 80.

6.5 Glazing in Sidelight and Transom Light Frames.

6.5.1 Glazing materials shall be capable of resisting the passage of smoke.

6.5.2* The perimeter of the glazing material and sidelight and transom frames shall be sealed to resist the passage of smoke at temperatures up to 400°F (204°C).

6.5.3 Glazing in sidelight and transom light frames that are required to be fire rated shall comply with NFPA 80.

6.6 Side Panel and Transom Panel Frames.

6.6.1 The perimeter of fixed solid panels used in side panel and transom panel frames shall be sealed to resist the passage of smoke.

6.6.2 Removable panels shall be permitted, provided they are gasketed to resist the passage of smoke.

6.7* Gasketing and Astragals.

6.7.1 Gasketing. Where required by the door listing, the gaps between the top and vertical edges of the door and frame and between the meeting edges of pairs of doors shall be closed with labeled gasketing material in accordance with the gasketing manufacturer's published listings.

6.7.1.1* Gasketing material shall form a continuous seal along the top and vertical edges of the doors and at meeting edges of pairs of doors.

6.7.1.2* Where mortising of doors to receive hardware items creates a void along the vertical or top edges of doors, soffit-mounted gasketing shall be required.

6.7.1.3 Where required, gaps between the bottom of the doors and the floor shall be closed with labeled gasketing in accordance with the gasketing manufacturer's published listing.

6.7.1.4 Automatic door bottoms that close the gap between the bottom of the door and the floor or threshold shall be permitted to be installed.

6.7.2 Astragals. Doors swinging in pairs, where located with a means of egress, shall not be equipped with astragals that inhibit the free use of either leaf.

Chapter 7 Installation, Testing, and Maintenance of Smoke Dampers

7.1* General. This chapter covers the requirements of the installation, testing, and maintenance of smoke dampers and combination fire and smoke dampers.

7.2 Definitions. (Reserved)

7.3 Installation.

7.3.1 Dampers.

7.3.1.1 Smoke dampers shall be installed within 24 in. (610 mm) of the partition and before any branch line or opening other than access panel and shall be installed in accordance with the manufacturer's installation instructions and the listing.

7.3.1.2 Damper actuator and linkage to operate the smoke damper shall be supplied and installed at the factory.

7.3.2 Dampers equipped with fusible links and/or internal operators shall be provided with an access door that is not less than 12 in.^{2} (7742 mm^2) or provided with a removable duct section.

7.3.2.1 Dampers that are installed behind registers, diffusers, or grilles shall be serviceable by removal of these covers.

7.3.2.2 A smoke damper access panel shall be labeled with the words "Smoke Damper" in letters not less than ½ in. (13 mm) in height. External insulation shall not conceal any access panel unless there is a label attached to the insulation clearly indicating the exact location of the access panel and the insulation is installed for ease of removal or ease of removal with the access panel.

7.3.2.3 Unobstructed access shall be provided through a ceiling or wall for inspection and service of the damper's working parts.

7.3.2.4 Installation of combination fire/smoke dampers shall be in accordance with the installation of fire dampers in NFPA 80, Section 19.2.

7.3.2.5 Smoke detectors used to control smoke dampers or fire/smoke dampers shall be spaced and installed per the requirements of *NFPA 72*.

7.4 Operational Test.

7.4.1 Smoke and Combination Fire/Smoke Dampers. An operational test shall be conducted after the building's HVAC system has been balanced.

7.4.1.1 The test shall be adequate to determine that the damper has been installed and functions as intended.

7.4.1.2 The operational test shall be conducted under normal HVAC airflow conditions as well as static flow conditions. The damper shall fully close/seal under both test conditions.

7.4.1.3 The operational test shall verify that there are no obstructions to the operation of the dynamic combination damper.

7.4.1.4 The operational test shall verify that there is full and unobstructed access to the dynamic combination damper and all appurtenances.

7.4.1.5 All indicating devices shall be verified to work properly and report to the intended location.

7.4.1.6 Combination fire/smoke dampers shall also meet the testing requirements contained in NFPA 80, Section 19.3.

7.5 Acceptance Testing.

7.5.1 Acceptance testing of smoke dampers shall be performed by a qualified person with knowledge and understanding of the operating components of the type of assembly to be tested.

7.5.2 Before testing, a visual inspection shall be performed to identify any damaged or missing parts that could create a hazard during testing or affect operation or resetting.

7.5.3* Acceptance testing shall include the closing of the damper by every means.

7.5.4 Acceptance testing shall be conducted after the building mechanical ventilation system has been balanced, and in operation under maximum air flow, if equipped with a variable air volume system in accordance with 5.2.1.

7.5.5 A record of these inspections and testing shall be made in accordance with 5.2.2.

7.6 Periodic Inspection and Testing.

7.6.1 General.

7.6.1.1 Smoke dampers for dedicated and nondedicated smoke control systems shall be inspected and tested in accordance with NFPA 92

7.6.1.2 Combination fire/smoke dampers shall be inspected and tested in accordance with NFPA 80.

7.6.2* Testing Frequency.

7.6.2.1 Each damper shall be tested and inspected 1 year after installation.

7.6.2.2* The test and inspection frequency shall then be every 4 years, except in buildings containing a hospital, where the frequency shall be every 6 years.

7.6.3 Test Method.

7.6.3.1 All tests shall be completed in a safe manner by personnel wearing personal protective equipment (PPE).

7.6.3.2 Fans shall not be permitted to be shut down during the test.

7.6.3.3 Dampers with Motorized Actuators. Testing of dampers with actuators shall comply with the following procedure:

(1) Visually confirm that the damper is in the fully-open position.
(2) Verify that all obstructions, including hands, are out of the path of the damper blades and then remove electrical power or air pressure from the actuator to allow the actuator's spring return feature to close the damper.
(3) Visually confirm that the damper closes completely.
(4) Reapply electrical power or air pressure to reopen the damper.
(5) Visually confirm that the damper is in the fully-open position.

7.6.4 Documentation.

7.6.4.1 All inspections and testing shall be documented indicating the location of the damper, date of inspection, name of inspector, and deficiencies discovered.

7.6.4.2 The documentation shall have space to indicate when and how the deficiencies were corrected.

7.6.4.3 All documentation shall be maintained for at least three test cycles and made available for review by the AHJ.

7.7 Maintenance.

7.7.1 Any reports of abrupt changes in airflow or noise from the duct system shall be investigated to verify that it is not related to damper operation.

7.7.2* All exposed moving parts of the damper shall be dry lubricated as required by the manufacturer.

7.7.3 If the damper is not operable, repairs shall begin as soon as possible.

7.7.4 Following any repairs, the damper shall be tested for proper operation in accordance with Section 7.6.

7.7.5 Smoke damper actuation shall be initiated at a time interval recommended by the actuator manufacturer.

7.7.6 All maintenance shall be documented and records shall be retained in accordance with 7.6.4.

Chapter 8 Smoke Protective Curtain Assemblies

8.1 General.

8.1.1* This chapter shall cover the installation, inspection, testing, and maintenance of smoke protective curtain assemblies installed to protect vertical openings.

8.1.2 Smoke protective curtain assemblies that are protecting vertical openings shall be air leakage tested in accordance with ANSI/UL 1784, *Air Leakage Tests of Door Assemblies.*

8.1.3 Smoke protective curtain assembles shall be identified by an "S" label attached to the bottom bar of the curtain indicating a maximum air leakage rate of 3 ft^3 /min/ft^2 (0.9 m^3/min /m^2) and the tested pressure differential of 0.1 in., 0.2 in., or 0.3 in. of water (25 Pa, 50 Pa, 75 Pa).

8.2 Mounting of Smoke Protective Curtain Assemblies.

8.2.1 Smoke protective curtain assemblies shall be mounted to supporting construction in accordance with their listing and with the manufacturer's installation instructions.

8.2.2 Items that are not a part of a smoke protective curtain assembly shall not be field attached to any component of a smoke protective curtain assembly.

8.2.3 Access to, and clearances between, surrounding construction and a smoke protective curtain assembly shall allow for required testing and maintenance.

8.3 Assembly Components.

8.3.1 Smoke protective curtain assemblies shall be either self-closing or automatic-closing.

8.3.1.1 Smoke protective curtain assemblies shall not have a delay in the initiation of closing of more than 10 seconds.

8.3.1.2 Smoke protective curtain assemblies shall have an average closing speed of not less than 6 in./sec (152 mm/sec) or more than 24 in./sec (610 mm/sec).

8.3.2* Curtains shall be permitted to be sewn by qualified persons in accordance with the manufacturer's instructions.

8.4 Power Operators. Power operators shall be provided with a standby or an emergency power source to close the curtain upon activation or shall be capable of closing the curtain without power.

8.5 Installation. Smoke protective curtain assemblies shall be installed in accordance with their listing and with the manufacturer's installation instructions.

8.6 Inspection, Testing, and Maintenance.

8.6.1 Following completion of installation, smoke protective curtains shall be inspected and tested in accordance with Section 8.7.

8.6.2 A record of all inspections and testing shall be signed by the inspector and kept for inspection by the AHJ.

8.6.2.1 Records of acceptance testing following completion of installation shall be retained for the life of the assembly.

8.6.2.2 Records of periodic inspections and testing shall be retained for a period of at least 3 years.

8.6.2.3 The records shall be on a medium that will survive the retention period. Paper or electronic media shall be permitted. [***72:***14.6.2.3]

8.6.2.4 A record of all inspections and testing shall be provided that includes, but is not limited to, the following information:

(1) Date of inspection
(2) Name of facility
(3) Address of facility
(4) Name of person(s) performing inspections and testing
(5) Company name and address of inspecting company
(6) Signature of inspector of record
(7) Individual record of each inspected and tested smoke protective curtain assembly
(8) Opening identifier and location of each inspected and tested smoke protective curtain
(9) Type and description of each inspected and tested smoke protective curtain
(10) Verification of visual inspection and functional operation
(11) Listing of any deficiencies

8.6.2.5 Upon completion of maintenance work, smoke protective curtain assemblies shall be inspected and tested in accordance with Section 8.7.

8.7 Acceptance Testing.

8.7.1 Acceptance testing of smoke protective curtain assemblies shall be performed by a qualified person with knowledge and understanding of the operating components of the type of assembly being subject to testing.

8.7.2 Before testing, a visual inspection shall be performed to identify any damaged or missing parts that can create a hazard during testing or affect operation or resetting.

8.7.3 Acceptance testing shall include the closing of the smoke protective curtain assembly by all means of activation.

8.7.4 A record of these inspections and testing shall be made in accordance with Section 8.6.

8.7.5 The following items shall be verified:

(1) Labels are clearly visible and legible.
(2) No open holes or breaks exist in surfaces of the curtain or in the stitching of the curtain.
(3) Curtain, guides, and coil are aligned, level, plumb, and true.
(4) Mounting and assembly bolts are intact and secured.
(5) Attachments to jambs are with bolts, expansion anchors, or as otherwise required by the listing.
(6) Smoke detectors, if equipped, are installed, operational, and in accordance with *NFPA 72*
(7) No parts are missing or broken.
(8) Auxiliary hardware items that interfere or prohibit operation are not installed on the curtain or frame.
(9) No field modifications to the smoke protective curtain assembly have been performed that void the label.
(10) Smoke protective curtain assemblies have an average closing speed of not less than 6 in./ sec (152 mm/sec) or more than 24 in./sec (610 mm/sec).

8.7.6 Smoke protective curtain assemblies shall be drop-tested twice.

8.7.7 Fusible links, release devices, and other movable parts shall not be painted or coated with other materials that could interfere with the operation of the assembly.

8.8 Closing Devices.

8.8.1 Smoke protective curtain assemblies shall be inspected and tested to check for proper operation and full closure.

8.8.2 Resetting of the automatic-closing device shall be performed in accordance with the manufacturer's instructions.

8.9 Periodic Inspection and Testing.

8.9.1 Periodic inspections and testing of smoke protective curtain assemblies shall be performed not less than annually.

8.9.2 As a minimum, the provisions of Section 8.7 shall be included in the periodic inspection and testing procedure.

8.10 Maintenance.

8.10.1 Repairs shall be made, and defects that could interfere with operation shall be corrected without delay.

8.10.2 Any breaks in the face covering of curtains shall be repaired in accordance with manufacturer's requirements without delay.

8.10.3 Where a smoke protective curtain assembly or any part of its appurtenances is damaged to the extent that it could impair the assembly's proper emergency function, the following actions shall be performed:

(1) The smoke protective curtain assembly or any part of its appurtenances shall be repaired with labeled parts or parts obtained from the original manufacturer.
(2) The smoke protective curtain assembly shall be tested to ensure emergency operation and closing upon completion of the repairs.

8.10.4 If repairs cannot be made with labeled components or parts obtained from the original manufacturer, the smoke protective curtain assembly or appurtenances shall be replaced.

Annex A Explanatory Material

Annex A is not a part of the requirements of this NFPA document but is included for informational purposes only. This annex contains explanatory material, numbered to correspond with the applicable text paragraphs.

A.1.2 For the purposes of this standard, smoke can be considered to be airborne particulates and gases resulting from combustion. Therefore, to understand smoke movement it is only necessary to understand air movement. Hot smoke, however, will be buoyant and will be located above the neutral plane in the fire compartment. As it moves away from the fire source, it will cool, lose its buoyancy, and become less stratified. Beyond the immediate influence of the fire, smoke will behave just as warm or cool air would behave. It will be driven by pressure differentials within the building, or it will follow air currents created by the heating, ventilating, and air-conditioning (HVAC) system or smoke management system in the building. Pressure differentials can be the result of the following:

(1) Fire pressure buildup, which would drive only the smoke out of the compartment or area of origin
(2) Stack effect due to temperature differentials between the interior and exterior of the building
(3) Wind
(4) Pressures created mechanically using HVAC systems, exhaust fans, supply or pressurization fans, vents, and smoke management systems

This standard has its beginnings in measurements from test results reported in *Operation School Burning* and from NFPA Technical Paper No. 341, "Factors in Controlling Smoke in High Buildings," where tenable or tolerable smoke concentration lists were established. Since the publication of *Operation School Burning* in 1959, considerable effort in the field of fire protection has been focused upon smoke movement in the built environment. NFPA *101* and NFPA 90A recognize that smoke control can be either active or passive. The passive approach recognizes the long-standing compartmentation concept, which requires that fans shut down and fire/smoke dampers in ductwork close under fire conditions. The active approach utilizes the building's HVAC systems to create differential pressures to prevent smoke migration from the fire area and to exhaust the products of combustion to the outside. Active smoke control systems use passive barrier components that include smoke door assemblies to create zones or areas for effective smoke movement as an essential component.

Smoke management utilizing active and passive methods in combination to modify smoke movement must be engineered into a system and focused on protection of property or people. While passive methods of smoke management do exist *(see* NFPA 204*)*, dynamic smoke control systems using mechanical equipment to meet design goals dominate. NFPA 92 is used for the design, installation, testing, operation, and maintenance of systems for smoke control and provides methodologies for determining smoke development in large spaces.

Smoke door assemblies are intended to maintain egress, allow for the rescue of the occupants, or allow occupants to remain in an area of refuge. The required duration of smoke protection can be equated with the path of egress. Evacuation typically starts in a room, progresses through a corridor, perhaps passes through a smoke barrier or horizontal exit, and proceeds through an entrance to the exit, which can be a stair enclosure, exit passageway, or the exit discharge. As with fire door assemblies, the longest time of protection is generally required at the entrance to an exit enclosure or horizontal exit, with shorter durations appropriate for preceding doors.

This path-of-egress arrangement is compatible with the protect-in-place concept as occupants are expected to be moved from one compartment to another for protection or, in some cases, protected in rooms other than the room of fire origin.

Occupancies not typical of this scenario include atria, malls, and open office plans. Areas of this sort can be adequately protected by reasonably tight-fitting doors without specific smoke door ratings because of the large volume of space involved.

A.1.3 While the use of smoke door assemblies will be helpful in reducing the flow of airborne gases, it is not assumed that using this standard obviates the concern over toxic combustion products.

NFPA *101* and building codes include specific requirements for smoke door assemblies and should be consulted in every instance. NFPA should be followed where fire door assemblies are used as smoke door assemblies.

The leakage characteristics of adjacent wall, ceiling, and floor assemblies should be considered. It is generally viewed to be of marginal benefit to install smoke door assemblies in locations where adjacent walls, ceilings, or floors do not effectively resist the passage of smoke. (For additional information, see ASHRAE/ICC/SFPE/NFPA *Handbook of Smoke Control Engineering.*)

For protection against smoke migration into spaces of large volume, a reasonably tight-fitting door can be considered adequate because of the relatively long time it would take for such a space to become untenable due to smoke. Conversely, the average 8 ft (2.4 m) high by 4 ft to 6 ft (1.2 m to 1.8 m) wide corridor can become untenable in less than 2 minutes, as shown in a test conducted in California and documented in *Operation School Burning*, where the fire room door was open.

Tests indicate that listed gaskets, if properly installed and maintained in accordance with manufacturer's instructions, do a good job of reducing smoke infiltration to a sufficient level to provide protection against smoke infiltration through the door assembly. In a fire condition, there would normally be a room of fire origin, and temperatures would be high in this area. Immediately outside the room of origin there might be warm smoke.

A.1.3.1 Smoke door assemblies used in locations likely to be in proximity to a fire can be exposed to elevated temperatures, including door assemblies separating rooms and corridors. Such door assemblies, whether rated as fire doors or not, should restrict the passage of smoke that can be heated to a temperature of 400°F (204°C). In a fully sprinklered building, protection against elevated-temperature smoke might not be necessary, and the criteria for protection against ambient-temperature smoke might be appropriate.

Mention should be made of the effects of automatic sprinkler protection on smoke. The activation of an automatic sprinkler occurs early in a flaming fire condition, usually within approximately 5 minutes after visible flaming is observed. Temperatures immediately drop to almost ambient, and smoke is driven to the floor and diffused throughout the available space. Smoke production rate is reduced as the fire size decreases and the temperature of the flame plume is reduced. The temperature of the smoke is also reduced to near ambient. Thus, in a sprinklered building it can be appropriate to treat smoke as if it were at or near ambient temperature. Fewer mitigating measures might be needed to control smoke movement since the production rate of smoke will be reduced. However, under a smoldering fire condition, sprinkler activation can be delayed and this, too, should be considered.

Fire door assemblies protecting stair enclosures and vestibules adjacent to stair enclosures, for example, are more likely to be exposed to ambient temperature smoke, provided there are no combustible materials in the enclosure. These doors can form part of a control system involving pressurized stairwells or vestibules. The air leakage characteristics of such door assemblies are an essential part of smoke control design.

A.1.3.2 See NFPA 92 for additional information on protection of elevator openings.

A.3.2.1 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

A.3.2.2 Authority Having Jurisdiction (AHJ). The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A.3.2.4 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A.3.3.6.2 Elevated Temperature. Depending on the function of the door, its location in relation to the fire, and the movement of hot gases and air, door assemblies might be exposed to elevated smoke temperatures. Warm smoke has an assumed temperature at the exposed face of the door at or near 400°F (204°C); hot smoke has an assumed temperature at the exposed face of the door in excess of 400°F (204°C). A nationally recognized standard test for measuring hot smoke temperature leakage does not exist.

It has been determined from many full-scale fire tests of compartments that the maximum instantaneous pressure differential created by an uncontrolled fire can approach 0.15 in. of water (37.5 Pa). More typically, a pressure differential of 0.06 in. of water to 0.10 in. of water (15 Pa to 25 Pa) is achieved over the period of most intense burning in light fire loading occupancies such as residential, health care, and business (offices).

In sprinklered buildings where the fire will be controlled, it is anticipated that the maximum pressure differential generated should not exceed 0.05 in. of water (12.5 Pa).

Typical stair pressurization systems can often result in pressure differentials as high as 0.25 in. of water to 0.50 in. of water (62.5 Pa to 125 Pa) across the door assembly.

Stack effect can also play a major role in determining pressure that must be overcome in order to pressurize shafts, such as elevators and stairs, to prevent smoke infiltration. Pressure differentials between the exterior and unvented shafts can range from virtually nothing to as much as 0.5 in. of water to 1.0 in. of water (125 Pa to 250 Pa) or more, depending on the location of the building neutral pressure plane, the height of the building, and the outside temperature. The ASHRAE/SFPE handbook, *Principles of Smoke Management,* addresses smoke management applications including pressurized stairwells, pressurized elevators, and pressure differentials that designers are likely to encounter.

The quantity of air movement through a door gap can be determined by the following general formula:

[A.3.3.4.2]

$$Q = KAP^{\frac{1}{N}}$$

where:
Q = volume flow rate of air
K = orifice coefficient for the gap around the door perimeter
A = area of the gap
P = pressure differential across the door
N = number between 1 and 2 that can be determined empirically

(For more information, see NFPA's *Fire Protection Handbook.*)

A.3.3.7 Tenable Environment. It is not expected that a tenable environment will be completely free of smoke. [**92**, 2015]

A.4.2.3 Hardware requiring extensive door mortising that could provide considerable air leakage through the door panel should be tested if required by the testing laboratory.

A.4.3.1 Smoke management systems both affect and are affected by smoke door assemblies. Pressurized stair enclosures, for example, are more easily engineered when leakage through the stair doors is reduced. In other areas, pressurization can inhibit smoke flow so that reasonably tight-fitting doors unrated for smoke protection can be entirely appropriate.

Complete sealing of doors is not always desirable. A disadvantage of complete sealing is the difficulty of opening or closing doors because of the pressure differential. Some smoke management designs call for some areas to be pressurized. A small pressure acting across the full area of a door can exert sufficient force to make opening a door difficult. A seal must be first broken to equalize the pressure on both sides of the door before the door can be opened easily.

Smoke doors should take the entire smoke management system into account. The amount of leakage tolerated will vary according to the degree of compartmentation, whether smoke management systems are used, and whether the building is protected by sprinklers.

An engineering evaluation should be performed when the volume of the space to be protected is known so that the values can be modified to restrict smoke leakage in terms of a specified smoke tenability level. In assessing tenability, the evaluation should include, but not be limited to, fuel load, pressurization, stack effect, presence of smoke control systems, and construction, as well as smoke leakage.

A.4.3.2 The artificial door bottom is used during the air-leakage tests of ANSI/UL 1784, *Air Leakage Tests of Door Assemblies*, to better ascertain the amount of air leakage along the vertical edges and across the top edge(s) of the doors. An example of an artificial door bottom is duct tape used to seal the gap between the bottom of the door and the sill during the air-leakage test. The application of gasketing at the door bottom on installed smoke door assemblies is sometimes required in areas that are pressurized for smoke control. In the majority of cases, it is not necessary to seal the gap under the door.

A.4.3.3 Test data exists for certain door types demonstrating that air leakage at ambient temperature is greater than warm air temperature leakage. In such instances, the air leakage rate for ambient temperature could also apply for warm temperatures when additional data tests are not conducted at elevated temperature.

A.4.3.4 Pressure differentials of at least 0.04 in. of water (10 Pa) are developed in the upper parts of rooms that are involved in fire. Considerably higher pressure differentials can exist in rooms, corridors, and stair enclosures due to the action of air-handling systems, stack effect, and wind.

In sprinklered buildings where the fire will be controlled, it is anticipated that the maximum pressure differential generated should not exceed 0.05 in. of water (12.5 Pa). See pressure differences discussed in NFPA 92 and ASHRAE/ICC/SFPE/NFPA *Handbook of Smoke Control Engineering*.

A.4.4 Non-fire-rated smoke doors might not be marked with an "S" label or any other markings that indicate the maximum air leakage rate. Gasketing manufacturers might be able to provide anecdotal information based on the testing of their products. Due to the size, shape, material, and configuration of gasketing products, the label frequently is marked on the packaging of the gasketing material rather than on the product. Verifying the maximum air leakage rate of a smoke door without a fire protection rating might require additional research if the door does not carry an "S" label.

A.5.1.3.1 Smoke door assemblies, both fire-rated and non-fire-rated, should be operable under normal conditions. Operability includes closing easily and completely and, where required, positively latching in the closed position. Operability, in the case of smoke door assemblies, also includes the sealing of the door against the passage of smoke. Fire-rated doors are not required to be operable after exposure to a fire. Similarly, non-fire-rated doors should not be expected to be operable after exposure to a fire.

A.5.1.5.2 Generally, the replacement of hardware components on swinging doors (hinges, pivots, door closers, etc.) is not considered to be a field modification, provided the replacement hardware does not require additional cutting, mortising, or boring into the doors and frames and the hardware meets the criteria specified elsewhere in the standard. Likewise, the installation of surface-mounted items like protection plates is not considered to be a field modification. Cutting doors for vision panels, enlarging existing cutouts for vision panels, and trimming doors in height or width are examples of field modifications, as is installing hardware components that require additional cutting and mortising of the doors or frames.

A.5.2.2 Newer technology includes the use of bar codes and other electronic devices. This section recognizes that completed and filed bar code reports should be considered signed by the inspector.

A.5.2.2.2 In many cases, AHJs are not able to inspect every building in their jurisdiction each year. Inspection and testing records need to be retained during the intervening periods between the AHJ's formal visits to provide evidence that the inspections and testing were performed as required by this standard. Additionally, maintenance records documenting that the necessary corrective actions have been made in accordance with this standard should be stored with the inspection and testing records for the same period of time. Retaining the records for 7 years allows the AHJ to look back over an extended period of time to verify that the smoke door assemblies are being properly maintained.

A.5.2.2.3 Installation of new smoke door assemblies should be documented in the same manner and level of detail as the periodic inspections and testing of smoke door assemblies required by 5.2.4 and 5.2.5. Records of new smoke door assemblies should be retained with the periodic inspections and testing records for the facility.

A.5.2.2.4(8) Each smoke door assembly in a facility should be assigned a unique identifier code (e.g., door number) that can be used to track the assembly's compliance and maintenance records throughout the lifetime of its installation. Identifier codes could be a door assembly number, bar code, or other code that is unique to each smoke door assembly in the facility.

A.5.2.2.4(9) To aid the AHJ during the review of the inspections and testing reports, the records should include a description of the smoke door assembly. The following door types are listed in NFPA 80 and could have application under this section:

(1) Swinging doors with builders hardware
(2) Swinging doors with fire door hardware
(3) Horizontally sliding doors
(4) Special purpose horizontally sliding accordion or folding doors
(5) Vertically sliding fire doors
(6) Rolling steel doors
(7) Fire shutters
(8) Service counter fire doors
(9) Hoistway doors for elevators and dumbwaiters
(10) Chute doors
(11) Access doors
(12) Fabric fire safety curtain

A.5.2.2.4(10) Functional operation of smoke door assemblies should include testing of the closing device, complete closure of the door from the full-open position, and full engagement of latch(es) where required by door type. Functional testing of automatic-closing or power-operated smoke door assemblies and electrically controlled latching hardware might need to be coordinated with the facility during other electrically controlled system tests. Where required by other standards, the force to open a door should be recorded using a door pressure gauge.

A.5.2.4 Visual inspection and functional testing of smoke door assemblies require the persons performing the inspections and testing to be thoroughly knowledgeable of the various components and systems that are used to create the assemblies. Inspectors of swinging doors should be able to recognize which components can or cannot be used on specific assemblies, which requires training and experience on the part of the persons performing the inspections. Additionally, AHJs should be able to rely on the competency, expertise, experience, and knowledge of the smoke door inspectors in their jurisdiction.

A.5.2.4.1 Any smoke door assembly or component that has a history of recurring failures should be evaluated for possible replacement or other corrective measures.

A.5.2.4.5.2(13) Fusible links should not be coated with any materials such as fireproofing, drywall compound, or spray texturing.

A.5.3 See Annex B for information regarding performance-based inspection, testing, and maintenance options for smoke door assemblies.

A.5.4.1 The determination of the time required for corrective action should be based on a risk analysis and the availability of replacement materials.

A.6.1 Swinging smoke door assemblies fall into two categories, fire rated and non–fire rated. Fire-rated smoke door assemblies are also required to comply with NFPA 80. Where there are conflicting requirements for fire-rated doors, NFPA 80's requirements take precedence over all other requirements. Additionally, building, fire, and life safety codes contain specific requirements that affect the design and installation of swinging smoke door assemblies. Some of the requirements of Chapter 6 have been adapted from the requirements found in Chapter 8 of NFPA 101.

Generally, swinging smoke door assemblies without fire protection rating are composed of many of the same components that are used on swinging fire door assemblies. In many cases, the internal construction of the door leaves is the main difference between the two categories of smoke door assemblies. Each type of swinging smoke door assembly utilizes the same types of frames, doors, and builders hardware (hinges, latching hardware, closing devices, etc.) and are virtually identical except for the labels that indicate the door is fire rated. For that reason, many of the requirements of Chapter 6 refer directly to NFPA 80 or otherwise adapt applicable NFPA 80 requirements for use on non-fire-rated swinging smoke door assemblies.

Many of the components used in non-fire-rated smoke door assemblies are not specifically tested or listed by nationally recognized testing laboratories for use on smoke door assemblies, with the exception of gasketing materials and products that have been subjected to testing in accordance with ANSI/UL1784, *Air Leakage Tests of Door Assemblies.*

Users of this standard are encouraged to review related codes and standards to determine the applicable requirements for a specific smoke door assembly. When competing requirements are found in the related codes and standards, the AHJ should be consulted to determine which requirements take precedence.

A.6.3 Non-fire-rated doors used as smoke doors in door openings that are not required to be protected by fire doors might be constructed of aluminum, fiberglass, hollow metal, steel, wood, or other suitable materials. Generally, non-fire-rated smoke door assemblies are required to be self-closing or automatic closing and swing easily and freely, which requires ball bearing or anti-friction bearing hinges or pivots. Smoke door assemblies are required to have positive latching hardware, unless otherwise specifically exempted by the applicable building, fire, or life safety code.

A.6.3.1 Door leaves used in smoke door assemblies without fire protection rating should be constructed of a design that resists the passage of smoke. Such doors might be 1 ¾ in. (44 mm) thick solid-bonded wood core doors, which include, but are not limited to, particleboard, agrifiber, structural composite lumber (SCL), and stave core doors. ANSI/WDMA I.S. 1A, *Industry Standard for Interior Architectural Wood Flush Doors*, and ANSI/WDMA I.S. 6A, *Industry Standard for Architectural Stile and Rail Doors*, give specifications governing the construction of solid-bonded wood core doors. Door leaves constructed of aluminum, fiberglass reinforced polyester (FRP), glass, hollow metal, and steel might also be acceptable for use in smoke door assemblies without fire protection ratings; manufacturers' technical data should be consulted to confirm the use of such door leaves in smoke door assemblies.

A.6.3.1.1 Beveling the vertical edges of composite and wood door leaves permits the door leaves to be undersized in width, from the nominal width of the door opening. This is less than doors that have squared vertical edges, thus reducing the clearance dimension between the vertical edges of the doors and the rabbets of the door frames. Industry practice is to bevel the vertical edges of doors ⅛ in.:2 in. (3 mm:51 mm), which results in a bevel of 3 degrees.

A.6.3.2.2 Door stops in the door frames are necessary elements that provide support for the installation of gasketing materials. Door frames with terminated stops are sometimes used in rooms and spaces where the floors are subject to frequent cleaning. Terminated stops convert the lowest portion of the door frames to a flat profile, eliminating corners where dirt and debris might be trapped. In these cases, smoke and draft control gasketing should extend the full height of the shortened frame soffit or door stop. See Figure A.6.3.2.2.

A.6.3.3 Additional information regarding clearances for doors can be found in ANSI/WDMA I.S. 1A, *Industry Standard for Interior Architectural Wood Flush Doors.* Clearances for stile and rail wood doors should be in accordance with ANSI/WDMA I.S. 6A, *Industry Standard for Architectural Stile and Rail Doors.* Clearances for standard hollow metal doors should be in accordance with ANSI/SDI A250.8, *Recommended Specifications for Standard Steel Doors and Frames*(SDI-100). Clearances for custom hollow metal doors should be in accordance with HMMA 840-07, *Guide Specification for Installation and Storage of Hollow Metal Doors and Frames.*

A.6.3.3.1 In some occupancies, the clearance between the bottom horizontal edge of the door and the floor covering is permitted to be a maximum of 1 in. (25 mm) on doors without fire protection ratings.

A.6.3.4 In most cases, doors are required to be equipped with positive-latching hardware. In some occupancy groups, building, fire, and life safety codes permit positive-latching hardware to be omitted on doors in smoke partitions to rooms such as toilet rooms, bathrooms, shower rooms, sink closets, and similar auxiliary spaces that do not contain flammable or combustible materials.

A.6.3.5.1 Typically, non-fire-rated interior side-hinged and pivoted doors with door closers, including smoke doors without fire protection rating, are required to have a reduced opening force of a maximum of 5 lbf (22 N) once the door leaves are set in motion, to meet accessibility standards such as ANSI A117, *Standard for Accessible and Usable Buildings and Facilities,* or the *Americans with Disabilities Act Accessibility Guidelines (ADAAG).* In some cases, a door closer with a reduced opening force might not be able to completely close a fully gasketed smoke door reliably, due to the additional pressure applied to the door when the face of the door contacts the perimeter gasketing during closing. Additionally, when positive-latching hardware is required, the door closer needs to overcome the friction of the latching hardware at the end of the closing cycle to completely close the door and cause it to latch.

Fire-rated doors are exempt from the 5 lbf (22 N) reduced opening force due to the recognized need for fire doors to reliably close and latch every time. Similarly, smoke doors without fire protection rating should be exempt from the reduced opening force requirement since their ability to resist the passage of smoke is compromised when the doors fail to close. The AHJ should be consulted for guidance when smoke doors without fire protection rating are not able to close reliably because they are equipped with reduced opening force door closers.

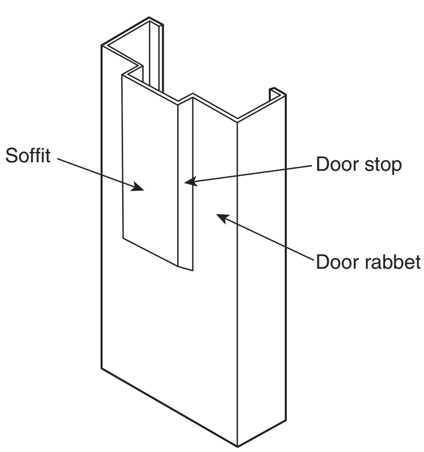

FIGURE A.6.3.2.2 Hollow Metal Door Frame with Terminated Stops.

A.6.3.6 Generally, builders hardware products include door hardware components such as conventional hinges, continuous hinges, pivots, floor concealed door closers, flush and automatic door bolts, bored and mortise locks and latches, fire exit hardware and panic hardware, surface-mounted door closers, low energy door operators, protection plates, door stops, and other hardware items. Smoke gasketing and intumescent gasketing products are considered to be builders hardware components. Builders hardware components are sold separately from the door frames and door leaves and are designed to fit into standardized preparations in the doors and frames in accordance with the ANSI/BHMA A156 series of product standards.

A.6.3.6.4 In general, NFPA 80's requirements for locks and latches are commensurate with industry practices for the installation of positive-latching hardware in smoke doors without fire protection rating and should be applied uniformly, where applicable, to smoke door assemblies.

Latching hardware devices include, but are not limited, to the following:

(1) Bored, mortise, and interconnected locks and latches
(2) Panic hardware
(3) Fire exit hardware
(4) Automatic flush bolts

A.6.3.6.6.2 In some occupancy groups, door-closing devices are not required to be installed on smoke door assemblies without fire protection ratings. In the absence of a means of holding doors open, occupants might block doors open with chocks, furniture, tie-downs, drop-down/plunger-type devices or other means. Examples of permitted door holder devices include friction catches (e.g., wall mounted, floor mounted, or overhead mounted) and magnetic catches.

Door holder/release devices for swinging doors should, wherever possible, be installed at the top of the door as close as possible to the lock edge and should be located to avoid interference with any other hardware. If necessary, the holder/release device can be located at the bottom of the door as close as possible to the lock edge, with the device installed on the wall or floor.

A.6.3.6.7 Armor, kick, mop, stretcher, and edge guards are types of protection plates. Protection plates should not be permitted to be used to conceal damage that compromises the structural integrity of the doors (i.e., split or delaminating vertical edges) or to conceal cutouts resulting from the removal of hardware items.

A.6.3.6.8 In most cases, the means of fastening for builders hardware products installed on non-fire-rated door assemblies is the same as the means of fastening for builders hardware products installed on fire-rated door assemblies. Installation practices such as drilling pilot holes or tapping holes in steel doors and frames are the same for fire-rated and non-fire-rated doors.

Some fasteners for builders hardware products have specially designed or undercut heads that are necessary to allow the fasteners to seat properly when installed. Use of fasteners from sources other than the respective hardware manufacturers should not be permitted to be used, since their use might affect door operation and might void the warranties of the affected hardware items.

A.6.5.2 The space between the glazing material and its frame or glazing bead should be completely filled with a material that is rated up to 400°F (204°C), forming a continuous seal around the perimeter of the vision panel, that resists the passage of smoke. Similarly, the space between the vision panel frame and the face of the door should be tightfitting or filled with the same material to resist the passage of smoke.

A.6.7 Gasketing for smoke door assemblies is available in a wide variety of sizes, shapes, materials, colors, and configurations. Some gasketing products are designed to be installed between the rabbet and door stops of the door frames and the doors with adhesive. Other gasketing products include aluminum or stainless steel channels of various profiles that are surface-mounted to the soffit of the door frame by means of mechanical fasteners such as sheet metal screws or self-drilling/self-tapping screws. Gasketing materials in soffit-mounted products include materials such as silicone and neoprene bulbs and sponges and nylon brushes.

A.6.7.1.1 Regardless of the design of gasketing applied to smoke door assemblies, the gasketing is of little value if it is not installed properly. The gasketing material should form an unbroken seal along the full height of the side jambs and across the head jambs and the full height of meeting edges of pairs of doors. Gasketing materials should not be permitted to be cut or notched to fit around other soffit-mounted hardware items such as door closer brackets (e.g., parallel arm brackets) or strikes for panic hardware and fire exit hardware devices. Similarly, astragals applied to the face of doors should not be permitted to be cut out or notched around protruding strike plate lips. Gasketing products should be installed in accordance with the gasketing manufacturer's installation instructions.

When properly installed, gasketing should contact the surface of the door, whether the gasketing is applied to the rabbets and stops or to the soffit area of the frame. A bright concentrated beam of light can be used to verify that the gasketing material blocks the light from passing through to the ungasketed side of the door, which should be indicative of the gasketing's ability to block the passage of smoke and gases.

A.6.7.1.2 Voids created in the door leaves, such as mortising the top rail of doors for overhead stops or concealed overhead door closers, require soffit-mounted gasketing to seal the top edge of the door. See Figure A.6.7.1.2.

A.6.7.1.3 Complete sealing of doors is not always desirable. A disadvantage of complete sealing is the difficulty of opening or closing doors because of the pressure differential. Some smoke management designs call for some areas to be pressurized. A small pressure acting across the full area of the door can exert sufficient force to make opening the door difficult. A seal must be first broken to equalize the pressure on both sides of the door before the door can be opened easily.

A.7.1 Smoke dampers are installed in ducts passing through, or air outlet openings terminating at, smoke barriers, shaft walls, horizontal exit walls, corridor walls, corridor ceilings, and other fire partitions designed to resist the spread of smoke as required by the model building code and other applicable NFPA codes and standards.

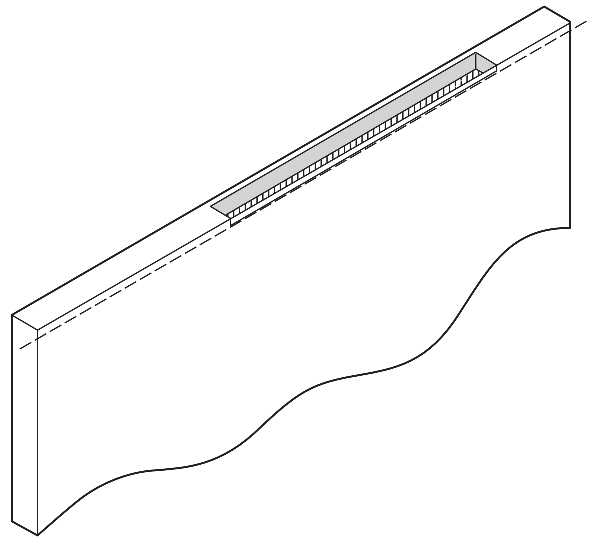

FIGURE A.6.7.1.2 Mortise Cutout in Top of Door Leaf for Overhead Door Stop. The dotted line represents the height of the door stop on the door frame. Gasketing should be installed on the soffit of the door frame so that it contacts the surface of the door below the cutout.

A.7.5.3 If the damper is equipped with a fusible link, it is not required to activate the link by heat to test the damper. Visual inspection should be made after the fusible link has been reinstalled to ensure it will not impede closing of the damper.

A.7.6.2 If the damper is arranged to be activated automatically, such as by a smoke detector or other device or system, the periodic test required by 7.6.2need not involve initiation of the detector or other device or system. The damper can be actuated and cycled as part of the associated smoke detector testing in accordance with *NFPA 72*. However, such testing does not meet all the testing and inspection requirements of NFPA 105. The *NFPA 72* testing could be combined with the inspection and testing requirements of NFPA 105, provided that all testing requirements of NFPA 105 are met. If operational issues are discovered during *NFPA 72* testing, they should be reported to the building owner for corrective measures as required by NFPA 105. For additional information, refer to NFPA 4.

A.7.6.2.2 See A.7.6.2.

A.7.7.2 Each damper should be examined to ensure that it is not rusted or blocked, with particular attention given to hinges and other moving parts.

A.8.1.1 Smoke protective curtain assemblies are not to be confused with fabric fire safety curtain assemblies, which are intended for use specifically on proscenium openings.

A.8.3.2 Sections of a smoke protective curtain may be sewn together when such joints are included in the assembly that was tested in accordance with UL 1784, *Air Leakage Tests of Door Assemblies.*

Annex B Performance-Based Option for the Inspection, Testing, and Maintenance of Smoke Door Assemblies

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

B.1 This annex provides the option to adopt a performance-based method as an alternative means of compliance with Section 5.2. Equivalent levels of performance can be demonstrated through quantitative performance-based analyses. This annex provides a basis for implementing a performance-based program acceptable under this option, provided that approval is obtained from the AHJ.

B.2 The concept of a performance-based program is to establish the type and frequency of inspection to demonstrate that the assembly is operational. The goal is to balance the inspection frequency with the proven reliability of the assembly. The goal of a performance-based inspection program is also to adjust test and inspection frequencies commensurate with documented historical equipment performance and desired reliability. Frequencies of tests and inspections under a performance-based program can be extended or reduced from the once-per-year test requirement in 5.2.5 when continued testing of door assemblies in 5.2.4, 5.2.4.4, or 5.2.4.5, as applicable, has been documented indicating a higher or lower degree of reliability compared with the AHJ's and the owner's expectations of performance. Additional program attributes that should be considered in the adjustment of test and inspection frequencies include the following:

(1) Door maintenance programs
(2) Door usage frequencies
(3) History of door repairs
(4) Building condition
(5) Consequence of failure

B.3 Fundamental to implementing a performance-based program is that adjusted test and inspection frequencies should be technically defensible to the AHJ and supported by evidence of higher or lower reliability. Data collection and retention should be established so that the data utilized to alter frequencies are representative, statistically valid, and evaluated against firm criteria. Frequencies cannot be arbitrarily extended or reduced without suitable rationale.

B.4 It must be noted that transitioning to a performance-based program requires an expenditure of resources in order to collect and analyze failure data, coordinate review efforts, change program documents, and seek approval from the AHJ. The following factors should be considered in determining whether a transition to a performance-based test program as permitted in Section 5.3 is warranted:

(1) *Past door reliability.* Have problems routinely been identified during the prescriptive test requirements of Section 5.2, or have doors consistently performed with minimal discrepancies noted?
(2) *Resource expenditures.* Do the recurring resource expenditures necessary to implement the prescriptive test requirements in Section 5.2 justify the consideration of conducting the detailed analyses needed to support a performance-based testing program?
(3) *Administrative burden.* Is there an increase to the administrative burden for implementing, documenting, and monitoring a performance-based program?

B.5 A performance-based program requires that a maximum allowable failure rate be established and approved by the AHJ in advance of implementation. The use of historic documented smoke door inspection records can be utilized to determine failure rates. One method of calculating the failure rate of smoke door assemblies is based on the following equation:

[B.5]

$$SDFR(t) = \frac{NF}{NC * t}$$

where:
$SDFR(t)$ = smoke door failure rate (failures per year)
NF = number of failures
NC = total number of smoke door assemblies inspected or tested
t = time interval of review (years)

B.6 Example. Data are collected for 50 smoke doors over a 5-year period. The testing is conducted annually as described in 5.2.5. A review of the data identifies five failures: total components, 50; data collection period, 5 years; total failures, 5.

[B.6]

$$SDFR = \frac{5}{50 \times 5} = 0.020 \text{ per year}$$

B.7 A fundamental requirement of a performance-based program is the continual monitoring of the door component failure rates and determining if they exceed the maximum allowable failure rates as agreed on with the AHJ. The process used to complete this review should be documented and repeatable.

B.8 Coupled with the ongoing review is a requirement for a formalized method of increasing or decreasing the frequency of testing and inspection when the door assemblies exhibit either a higher than expected failure rate or an increase in reliability as a result of a decrease in failures.

B.9 A formal process for reviewing the failure rates and increasing or decreasing the frequency of testing should be well documented. The frequency required for future tests can be reduced to the next inspection frequency and maintained there for a period equaling the initial data review or until the ongoing review indicates that the failure rate is no longer being exceeded.

B.10 Increases and decreases in inspection frequency should be initiated on a step approach such that increments do not exceed 50 percent of the required frequency in 5.2.4, that is, 6 months for any given period under consideration. An example would be going from annual to semi-annual testing when the failure rate exceeds the AHJ's expectations or from annual testing to testing every 18 months when the failure trend indicates an increase in reliability. The maximum time period between inspections regardless of performance should not exceed 36 months. Changes in occupancy, facility management, or ownership that could result in changes in performance should be reassessed by the AHJ to determine if continued acceptability of a performance-based inspection program is warranted.

NFPA®110

Standard for

Emergency and Standby Power Systems

2016 Edition

This edition of NFPA 110, *Standard for Emergency and Standby Power Systems,* was prepared by the Technical Committee on Emergency Power Supplies and released by the Correlating Committee on National Electrical Code®. It was issued by the Standards Council on May 26, 2015, with an effective date of June 15, 2015, and supersedes all previous editions.

This edition of NFPA 110 was approved as an American National Standard on June 15, 2015.

Origin and Development of NFPA 110

The Technical Committee on Emergency Power Supplies was organized in 1976 by NFPA in recognition of the demand for viable guidelines for the assembly, installation, and performance of electrical power systems used to supply critical and essential needs during outages of the primary power source. The intent was to establish the equipment requirements necessary to achieve an on-site auxiliary electrical power source suitable to the needs of the applicable requirements and user criteria.

In 1979, the Committee's report proposing adoption of NFPA 110 was published but withdrawn because of issues involving the scope of the committee. In 1981, a revised report was returned to the Committee to resolve differences with other NFPA documents. At the 1982 NFPA Fall Meeting, the Committee's report was adopted as a tentative standard (NFPA 110T-1983) in order to expose the document to public review.

NFPA 110 was formally adopted as a standard at the 1984 NFPA Fall Meeting and designated as the 1985 edition, which clarified scope statements, prototype testing, battery and bypass-isolation switch requirements, and revised maintenance requirements.

The 1988 edition included several new definitions and further clarified transfer switch and installation testing requirements.

The 1993 edition reflected the adoption of NFPA 111, *Standard on Stored Electrical Energy Emergency and Standby Power Systems,* a basic requirement for one-step loading for all prime movers, an update on battery technology, restrictions on unnecessary transferring of loads, and the need for battery maintenance.

The 1996 edition added revised monthly load testing requirements for generator sets, consideration for potential wet stacking, various types of fuel tanks and spillage considerations, restrictions on the types of permitted batteries, and working space requirements. It also clarified the minimum number of cranks that an engine must be capable of completing, cooling system requirements, and timing devices in health care facilities for testing a generator.

The 1999 edition deleted the testing of generator sets at 50 percent of the emergency power supply system load because the relevant measure is the nameplate rating. The exception for wet stacking was also deleted. Exhaust temperature monitoring was added because it is an acceptable performance measure of proper emergency power supply loading.

The 2002 edition was restructured to comply with the *Manual of Style for NFPA Technical Committee Documents.* Introductory material in Chapter 1 was formatted for consistency among all NFPA documents. Referenced publications were relocated from the last chapter to Chapter 2, resulting in the renumbering of chapters. Definitions in Chapter 3 were made consistent with definitions in other NFPA documents, systematically aligned, and individually numbered. Paragraphs were revised to provide one mandatory requirement per section, subsection, or paragraph. Information that accompanied many of the requirements was moved to Annex A, Explanatory Material. Many exceptions were deleted or rephrased into mandatory text.

NFPA and National Fire Protection Association are registered trademarks of the National Fire Protection Association, Quincy, Massachusetts 02169.

Changes in the 2002 edition included definitive and broad-based requirements regarding electrical installations in accordance with *NFPA 70®, National Electrical Code®*; additional EPS controls and safeguards, such as alerting staff of impending failure of the EPS to start; access and working space around the generator set; ventilation; energy converters; and EPSS testing requirements.

The 2005 edition revised clearance distances between transfer switches and service equipment, revised the definitions for both lead-acid (flooded) and valve-regulated lead-acid (VRLA) batteries, and changed the testing and maintenance section to include testing for spark-ignited engines that parallels those for diesel. Changes also included new annex material for diesel fuel testing and maintenance procedures, as well as transfer switches.

Significant revisions to the 2010 edition included the following:

(1) Clarified that the requirements to systems classed as optional standby is not mandatory
(2) Clarified that the operation testing and routine maintenance requirements of Chapter 8 cover both new and existing EPSSs
(3) Aligned the definitions of transfer switch types with NFPA 111 and relevant product standards
(4) Revised the Chapter 7 requirements for acceptance testing and differentiated what is required for new and unoccupied buildings and facilities from what is required for existing occupied buildings and facilities
(5) Revised the Chapter 8 requirements for operational test durations, loading conditions, and method of test initiation for the emergency power supply

A noteworthy change for the 2013 edition was the deletion of the mandatory 96-hour fuel supply requirement (5.1.2) for seismic categories. The need for continued operation and the minimum operational time without refueling is a design consideration or is directed by another standard. Several references to ASTM standards and additional annex material were added to address fuel quality and storage issues. The prime mover cooling and ventilation system construction and installation requirements were reorganized.

The 2016 edition prohibits the installation of an automatically actuated valve into the fuel lines, in order to prevent the inadvertent cutoff of fuel at critical times. The proper operation of systems connected in parallel has been addressed by adding acceptance testing and maintenance items for paralleling gear. In order to test all transfer switches, a requirement to rotate the transfer switch initiating the monthly test has been added where multiple transfer switches are installed. A new section consolidates record management and defines record retention requirements.

This list represents the membership at the time the Committee was balloted on the final text of this edition. Since that time, changes in the membership may have occurred. A key to classifications is found at the back of the document.

NOTE: Membership on a committee shall not in and of itself constitute an endorsement of the Association or any document developed by the committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on performance criteria for the selection and assembly of the components for emergency and standby power systems in buildings and facilities, including categories of power supplies, transfer equipment, controls, supervisory equipment, and all related electrical and mechanical auxiliary or accessory equipment needed to supply emergency or standby power to the utilization equipment. The Committee also shall be responsible for criteria on the maintenance and testing of the system. This Committee does not cover requirements for the application of emergency power systems, self-contained emergency lighting units, and electrical wiring, except that wiring that is an integral part of the system up to the load side of the transfer switch(es). This Committee shall report to Technical Correlating Committee of the National Electrical Code.

NFPA 110

Standard for

Emergency and Standby Power Systems

2016 Edition

IMPORTANT NOTE: This NFPA document is made available for use subject to important notices and legal disclaimers. These notices and disclaimers appear in all publications containing this document and may be found under the heading "Important Notices and Disclaimers Concerning NFPA Documents." They can also be obtained on request from NFPA or viewed at www.nfpa.org/disclaimers.

UPDATES, ALERTS, AND FUTURE EDITIONS: New editions of NFPA codes, standards, recommended practices, and guides (i.e., NFPA Standards) are released on scheduled revision cycles. This edition may be superseded by a later one, or it may be amended outside of its scheduled revision cycle through the issuance of Tentative Interim Amendments (TIAs). An official NFPA Standard at any point in time consists of the current edition of the document, together with any TIAs and Errata in effect. To verify that this document is the current edition or to determine if it has been amended by any TIAs or Errata, please consult the National Fire Codes® Subscription Service or visit the Document Information (DocInfo) pages on the NFPA website at www.nfpa.org/docinfo. In addition to TIAs and Errata, the DocInfo pages also include the option to sign up for Alerts for each document and to be involved in the development of the next edition.

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates that explanatory material on the paragraph can be found in Annex A.

Information on referenced publications can be found in Chapter 2 and Annex C.

Chapter 1 Administration

1.1 Scope. This standard contains requirements covering the performance of emergency and standby power systems providing an alternate source of electrical power to loads in buildings and facilities in the event that the primary power source fails.

1.1.1 Power systems covered in this standard include power sources, transfer equipment, controls, supervisory equipment, and all related electrical and mechanical auxiliary and accessory equipment needed to supply electrical power to the load terminals of the transfer equipment.

1.1.2 This standard covers installation, maintenance, operation, and testing requirements as they pertain to the performance of the emergency power supply system (EPSS).

1.1.3 This standard does not cover the following:

(1) Application of the EPSS
(2) Emergency lighting unit equipment
(3) Distribution wiring
(4) Utility service when such service is permitted as the EPSS
(5) Parameters for stored energy devices
(6) The equipment of systems that are not classed as Level 1 or Level 2 systems in accordance with Chapter 4 of this standard

1.1.4* This standard does not establish criteria for stored energy systems.

1.1.5 The selection of any of the following is not within the scope of this standard:

(1) Specific buildings or facilities, or both, requiring an EPSS
(2) Specific loads to be served by the EPSS
(3)* Assignment of type, class, or level to any specific load

1.2 Purpose. This standard contains performance requirements for an EPSS.

1.2.1 It is the role of other NFPA standards to specify which occupancies require an EPSS and the applicable level, type, and class. This standard does not specify where an EPSS is required.

1.2.2 This standard also is intended to provide guidance for inspectors, designers, installers, manufacturers, and users of EPSSs and to serve as a vehicle for communication between the parties involved. It is not intended as a design manual.

1.2.3 Compliance with this standard is not intended to exempt the parties involved from their respective responsibilities for the design, installation, maintenance, performance, or compliance with other applicable standards and codes.

1.3 Application. This document applies to new installations of EPSSs, except that the requirements of Chapter 8 shall apply to new and existing systems. Existing systems shall not be required to be modified to conform, except where the authority having jurisdiction determines that nonconformity presents a distinct hazard to life.

1.4 Equivalency. Nothing in this standard is intended to prevent the use of systems, methods, or devices of equivalent or superior quality, strength, fire resistance, effectiveness, durability, and safety to those prescribed by this standard.

1.4.1* Technical documentation shall be submitted to the authority having jurisdiction to demonstrate equivalency.

1.4.2 The system, method, or device shall be approved for the intended purpose by the authority having jurisdiction.

Chapter 2 Referenced Publications

2.1 General. The documents or portions thereof listed in this chapter are referenced within this standard and shall be considered part of the requirements of this document.

2.2 NFPA Publications. National Fire Protection Association, 1 Batterymarch Park, Quincy, MA 02169-7471.

NFPA 30, *Flammable and Combustible Liquids Code,* 2015 edition.
NFPA 37, *Standard for the Installation and Use of Stationary Combustion Engines and Gas Turbines,* 2014 edition.
NFPA 54, *National Fuel Gas Code,* 2015 edition.
NFPA 58, *Liquefied Petroleum Gas Code,* 2014 edition.
NFPA 70®, National Electrical Code®, 2014 edition.
NFPA 72®, National Fire Alarm and Signaling Code, 2013 edition.
NFPA 99, *Health Care Facilities Code,* 2015 edition.
NFPA 780, *Standard for the Installation of Lightning Protection Systems,* 2014 edition.

2.3 Other Publications.

2.3.1 ASCE Publications. American Society of Civil Engineers, 1801 Alexander Bell Drive, Reston, VA 20191.

ASCE/SEI 7, *Minimum Design Loads for Buildings and Other Structures,* 2010.

2.3.2 Other Publications.

Merriam-Webster's Collegiate Dictionary, 11th edition, Merriam-Webster, Inc., Springfield, MA, 2003.

2.4 References for Extracts in Mandatory Sections.

NFPA 1, *Fire Code,*2015 edition.

Chapter 3 Definitions

3.1 General. The definitions contained in this chapter shall apply to the terms used in this standard. Where terms are not defined in this chapter or within another chapter, they shall be defined using their ordinarily accepted meanings within the context in which they are used. *Merriam-Webster's Collegiate Dictionary*, 11th edition, shall be the source for the ordinarily accepted meaning.

3.2 NFPA Official Definitions.

3.2.1* Approved. Acceptable to the authority having jurisdiction.

3.2.2* Authority Having Jurisdiction (AHJ). An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

3.2.3 Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

3.2.4* Listed. Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

3.2.5 Shall. Indicates a mandatory requirement.

3.2.6 Should. Indicates a recommendation or that which is advised but not required.

3.2.7 Standard. A document, the main text of which contains only mandatory provisions using the word "shall" to indicate requirements and which is in a form generally suitable for mandatory reference by another standard or code or for adoption into law. Nonmandatory provisions are not to be considered a part of the requirements of a standard and shall be located in an appendix, annex, footnote, informational note, or other means as permitted in the *Manual of Style for NFPA Technical Committee Documents*.

3.3 General Definitions.

3.3.1* Battery Certification. The certification by a battery manufacturer that a battery is built to industry standards.

3.3.2 Black Start. Where the stored energy system has the capability to start the prime mover without using energy from another source.

3.3.3* Emergency Power Supply (EPS). The source of electric power of the required capacity and quality for an emergency power supply system (EPSS).

3.3.4* Emergency Power Supply System (EPSS). A complete functioning EPS system coupled to a system of conductors, disconnecting means and overcurrent protective devices, transfer switches, and all control, supervisory, and support devices up to and including the load terminals of the transfer equipment needed for the system to operate as a safe and reliable source of electric power.

3.3.5 Fuel Tank.

3.3.5.1 ***Day Fuel Tank.*** A fuel tank, located inside a structure, that provides fuel to the engine.

3.3.5.2 ***Enclosed Fuel Tank.*** A fuel tank located within a separate room, separated from other equipment.

3.3.5.3 ***Integral Fuel Tank in EPS Systems.*** A fuel tank furnished by the EPS supplier and mounted on the engine or under as a subbase.

3.3.5.4 ***Main Fuel Tank.*** A separate, main fuel tank for supplying fuel to the engine or a day tank.

3.3.6 Lamp. An illuminating indicator.

3.3.7 Lead-Acid Battery.

3.3.7.1* ***Valve-Regulated (VRLA).*** A lead-acid battery consisting of sealed cells furnished with a valve that opens to vent the battery whenever the internal pressure of the battery exceeds the ambient pressure by a set amount. [**1:**2015]

3.3.7.2* ***Vented (Flooded).*** A lead-acid battery consisting of cells that have electrodes immersed in liquid electrolyte.

3.3.8 Occupancy Category. See ASCE/SEI 7, *Minimum Design Loads for Buildings and Other Structures.*

3.3.9 Qualified Person. One who has skills and knowledge related to the operation, maintenance, repair, and testing of the EPSS equipment and installations and has received safety training to recognize and avoid the hazards involved.

3.3.10 Switch.

3.3.10.1 ***Automatic Transfer Switch (ATS).*** Self-acting equipment for transferring the connected load from one power source to another power source.

3.3.10.2 ***Bypass-Isolation Switch.*** A manually operated device used in conjunction with an automatic transfer switch to provide a means of directly connecting load conductors to a power source and disconnecting the automatic transfer switch.

3.3.10.3 ***Nonautomatic Transfer Switch.*** A device, operated manually by a physical action or electrically by either a local or remote control, for transferring a common load between a normal and alternate supply.

Chapter 4 Classification of Emergency Power Supply Systems (EPSSs)

4.1* General. The EPSS shall provide a source of electrical power of required capacity, reliability, and quality to loads for a length of time as specified in Table 4.1(a) and within a specified time following loss or failure of the normal power supply as specified in Table 4.1(b).

4.2* Class. The class defines the minimum time, in hours, for which the EPSS is designed to operate at its rated load without being refueled or recharged. *[See Table 4.1(a).]*

4.3 Type. The type defines the maximum time, in seconds, that the EPSS will permit the load terminals of the transfer switch to be without acceptable electrical power. Table 4.1(b) provides the types defined by this standard.

4.4* Level. This standard recognizes two levels of equipment installation, performance, and maintenance.

4.4.1* Level 1 systems shall be installed where failure of the equipment to perform could result in loss of human life or serious injuries.

4.4.2* Level 2 systems shall be installed where failure of the EPSS to perform is less critical to human life and safety.

4.4.3* All equipment shall be permanently installed.

4.4.4* Level 1 and Level 2 systems shall ensure that all loads served by the EPSS are supplied with alternate power that meets all the following criteria:

(1) Of a quality within the operating limits of the load
(2) For a duration specified for the class as defined in Table 4.1(a)
(3) Within the time specified for the type as defined in Table 4.1(b)

Table 4.1(a) Classification of EPSSs

Class	Minimum Time
Class 0.083	0.083 hr (5 min)
Class 0.25	0.25 hr (15 min)
Class 2	2 hr
Class 6	6 hr
Class 48	48 hr
Class X	Other time, in hours, as required by the application, code, or user

Table 4.1(b) Types of EPSSs

Designation	Power Restoration
Type U	Basically uninterruptible (UPS systems)
Type 10	10 sec
Type 60	60 sec
Type 120	120 sec
Type M	Manual stationary or nonautomatic — no time limit

Chapter 5 Emergency Power Supply (EPS): Energy Sources, Converters, and Accessories

5.1 Energy Sources.

5.1.1* The following energy sources shall be permitted to be used for the emergency power supply (EPS):

(1)* Liquid petroleum products at atmospheric pressure as specified in the appropriate ASTM standards and as recommended by the engine manufacturer
(2)* Liquefied petroleum gas (liquid or vapor withdrawal) as specified in the appropriate ASTM standards and as recommended by the engine manufacturer
(3)* Natural or synthetic gas

Exception: For Level 1 installations in locations where the probability of interruption of off-site fuel supplies is high, on-site storage of an alternate energy source sufficient to allow full output of the EPSS to be delivered for the class specified shall be required, with the provision for automatic transfer from the primary energy source to the alternate energy source.

5.1.2 The energy sources listed in 5.1.1 shall be permitted to be used for the EPS where the primary source of power is by means of on-site energy conversion, provided that there is separately dedicated energy conversion equipment on-site with a capacity equal to the power needs of the EPSS.

5.1.3* A public electric utility that has a demonstrated reliability shall be permitted to be used as the EPS where the primary source is by means of on-site energy conversion.

5.2 Energy Converters — General.

5.2.1 Energy converters shall consist only of rotating equipment as indicated in 5.2.4.

5.2.1.1 Level 1 energy converters shall be representative products built from components that have proven compatibility and reliability and are coordinated to operate as a unit.

5.2.1.2 The capability of the energy converter, with its controls and accessories, to survive without damage from common and abnormal disturbances in actual load circuits shall be demonstrable by tests on separate prototype models, or by acceptable tests on the system components as performed by the component suppliers, or by tests performed in the listing process for the assembly.

5.2.1.3 A separate prototype unit shall be permitted to be utilized in a Level 1 or Level 2 installation, provided that all prototype tests produce no deleterious effects on the unit, and the authority having jurisdiction, the owner, and the user are informed that the unit is the prototype test unit.

5.2.2* The rotating equipment prototype unit shall be tested with all typical prime mover accessories that affect its power output in place and operating, including, but not limited to, the following:

(1) Battery-charging alternator
(2) Water pump
(3) Radiator fan for unit-mounted radiators or oil coolers (or comparable load)
(4) Fuel pump and fuel filter(s)
(5) Air filter(s)
(6) Exhaust mufflers or restriction simulating the maximum backpressure recommended by the prime mover manufacturer

5.2.3 The energy converter for Level 1 systems shall be specifically designed, assembled, and tested to ensure system operation under the following conditions:

(1) Short circuits
(2) Load surges due to motor starting
(3) Elevator operations
(4) Silicon controlled rectifier (SCR) controllers
(5) X-ray equipment
(6) Overspeed, overtemperature, or overload
(7) Adverse environmental conditions

5.2.4 Rotating equipment shall consist of a generator driven by one of the following prime mover types:

(1) Otto cycle (spark ignited)
(2) Diesel cycle
(3) Gas turbine cycle

5.2.4.1 Other types of prime movers and their associated equipment meeting the applicable performance requirements of this standard shall be permitted, if acceptable to the authority having jurisdiction.

5.2.4.2 Where used for Level 1 applications, the prime mover shall not mechanically drive any equipment other than its operating accessories and its generator.

5.2.5 The EPS shall be installed in accordance with *NFPA 70, National Electrical Code*.

5.3 Energy Converters — Temperature Maintenance.

5.3.1 The EPS shall be heated as necessary to maintain the water jacket and battery temperature determined by the EPS manufacturer for cold start and load acceptance for the type of EPSS.

5.3.2 All prime mover heaters shall be automatically deactivated while the prime mover is running. *(For combustion turbines, see 5.3.5.)*

5.3.2.1 Air-cooled prime movers shall be permitted to employ a heater to maintain lubricating oil temperature as recommended by the prime mover manufacturer.

5.3.3 Antifreeze protection shall be provided according to the manufacturer's recommendations.

5.3.4 Ether-type starting aids shall not be permitted.

5.3.5 The ambient air temperature in the EPS equipment room or outdoor housing containing Level I rotating equipment shall be not less than 4.5°C (40°F).

5.4* Energy Converters — Capacity. The energy converters shall have the required capacity and response to pick up and carry the load within the time specified in Table 4.1(b) after loss of primary power.

5.5 Energy Converters — Fuel Supply.

5.5.1 The fuel supplies specified in 5.1.1(1) and 5.1.1(2) for energy converters intended for Level 1 use shall not be used for any other purpose. *(For fuel system requirements, see Section 7.9.)*

5.5.1.1 Enclosed fuel tanks shall be permitted to be used for supplying fuel for other equipment, provided that the drawdown level or other passive features are designed into the fuel system to guarantee that the required quantity of fuel is available for the EPSS.

5.5.1.2 Vapor-withdrawal LP-Gas systems shall have a dedicated fuel supply.

5.5.2* A low-fuel sensing switch shall be provided for the main fuel supply tank(s) using the energy sources listed in 5.1.1(1) and 5.1.1(2) to indicate when less than the minimum fuel necessary for full load running, as required by the specified class in Table 4.1(a), remains in the main fuel tank.

5.5.3* The main fuel tank shall have a minimum capacity of at least 133 percent of either the low-fuel sensor quantity specified in 5.5.2 or the quantity required to support the duration of run specified in Table 4.1(a).

5.6 Rotating Equipment.

5.6.1 General. Prime movers and accessories shall comply with NFPA 37, *Standard for the Installation and Use of Stationary Combustion Engines and Gas Turbines*, except as modified in this standard.

5.6.2 Prime Mover Ratings. Proper derating factors, such as altitudes, ambient temperature, fuel energy content, accessory losses, and site conditions as recommended by the manufacturer of the generator set shall be used in determining whether or not brake power meets the connected load requirements.

5.6.3 Prime Mover Accessories.

5.6.3.1 Governors shall maintain a bandwidth of rated frequency for any constant load (steady-state condition) that is compatible with the load.

5.6.3.1.1 The frequency droop between no load and full load shall be within the range for the load.

5.6.3.1.2 The frequency dip upon one-step application of the full load shall not be outside the range for the load, with a return to steady-state conditions occurring within the requirements of the load.

5.6.3.2 Solenoid valves, where used, both in the fuel line from the supply or day tank closest to the generator set and in the water-cooling lines, shall operate from battery voltage.

5.6.3.2.1 Solenoid valves shall have a manual (nonelectric) operation, or a manual bypass valve shall be provided.

5.6.3.2.1.1 The manual bypass valve shall be visible and accessible and its purpose identified.

5.6.3.2.1.2 The fuel bypass valve shall not be the valve used for malfunction or emergency shutdown.

5.6.3.3 The prime mover shall be provided with the following instruments:

(1) Oil pressure gauge to indicate lubricating oil pressure when a pressurized lubricating system is provided
(2) Temperature gauge to indicate cooling medium temperature when a liquid medium cooling system is used
(3) Hour meter to indicate actual total running time
(4) Battery-charging meter indicating performance of prime mover–driven battery charging means
(5) Other instruments as recommended or provided by the prime mover manufacturer where required for maintenance

5.6.3.4 The instruments required in 5.6.3.3(1) through 5.6.3.3(4) shall be placed on an enclosed panel, located in proximity to or on the energy converter, in a location that allows maintenance personnel to observe them readily. The enclosed panel shall be mounted by means of antishock vibration mountings if mounted on the energy converter.

5.6.3.5 All wiring for connection to the control panel shall be harnessed or flexibly enclosed, shall be securely mounted on the prime mover to prevent chafing and vibration damage, and shall terminate at the control panel in an enclosed box or panel. *(For control panel requirements, see 5.6.5.)*

5.6.3.6 The generator set shall be fitted with an integral accessory battery charger, driven by the prime mover and automatic voltage regulator, and capable of charging and maintaining the starting battery unit (and control battery, where used) in a fully charged condition during a running condition.

5.6.3.6.1 A battery charger driven by the prime mover shall not be required, provided the automatic battery charger has a high-low rate capable of fully charging the starting battery during running conditions as specified in 5.6.3.6.

5.6.4 Prime Mover Starting Equipment.

5.6.4.1 Starting Systems. Starting shall be accomplished using either an electric starter or a stored energy starting system.

5.6.4.1.1 Electric starter systems shall start using a positive shift solenoid to engage the starter motor and to crank the prime mover for the period specified in 5.6.4.2 without overheating, at a speed at least equal to that recommended by the manufacturer of the prime mover and at the lowest ambient temperature anticipated at the installation site.

5.6.4.1.2 Other types of stored energy starting systems (except pyrotechnic) shall be permitted to be used where recommended by the manufacturer of the prime mover and subject to approval of the authority having jurisdiction, under the following conditions:

(1) Where two complete periods of cranking cycles are completed without replacement of the stored energy
(2) Where a means for automatic restoration from the emergency source of the stored energy is provided
(3) Where the stored energy system has the cranking capacity specified in 5.6.4.2.1
(4) Where the stored energy system has a "black start" capability in addition to normal discharge capability

5.6.4.2* Otto or Diesel Cycle Prime Movers. For otto or diesel cycle prime movers, the type and duration of the cranking cycle shall be as specified in Table 5.6.4.2.

5.6.4.2.1 A complete cranking cycle shall consist of an automatic crank period of approximately 15 seconds followed by a rest period of approximately 15 seconds. Upon starting and running the prime mover, further cranking shall cease.

5.6.4.2.2 Two means of cranking termination shall be utilized so that one serves as backup to prevent inadvertent starter engagement.

5.6.4.2.3 Otto cycle prime movers of 15 kW and lower and all diesel prime movers shall be permitted to use continuous cranking methods.

5.6.4.3* Number of Batteries. Each prime mover shall be provided with both of the following:

(1) Storage battery units as specified in Table 5.6.4.2
(2) A storage rack for each battery or battery unit

Table 5.6.4.2 Starting Equipment Requirements

	Starting Equipment Requirements	Level 1	Level 2
(a)	Battery unit	X	X
(b)	Battery certification	X	NA
(c)	Cycle cranking	X or O	O
(d)	Cranking limiter time-outs		
	Cycle crank (3 cycles)	75 sec	75 sec
	Continuous crank	45 sec	45 sec
(e)	Float-type battery charger	X	X
	dc ammeter	X	X
	dc voltmeter	X	X
(f)	Recharge time	24 hr	36 hr
(g)	Low battery voltage alarm contacts	X	X

X: Required. O: Optional. NA: Not applicable.

5.6.4.4* Size of Batteries. The battery unit shall have the capacity to maintain the cranking speed recommended by the prime mover manufacturer through two complete periods of cranking limiter time-outs as specified in Table 5.6.4.2, item (d).

5.6.4.5 Type of Battery. The battery shall be of the nickel-cadmium or lead-acid type.

5.6.4.5.1* Lead-acid batteries shall be furnished as charged when wet. Drain-dry batteries or dry-charged lead-acid batteries shall be permitted.

5.6.4.5.2 When furnished, vented nickel-cadmium batteries shall be filled and charged and shall have listed flip-top, flame arrester vent caps.

5.6.4.5.3 The manufacturer shall provide installation, operation, and maintenance instructions and, for batteries shipped dry, electrolyte mixing instructions.

5.6.4.5.4 Batteries shall not be installed until the battery charger is in service.

5.6.4.5.5 All batteries used in this service shall have been designed for this duty and shall have demonstrable characteristics of performance and reliability acceptable to the authority having jurisdiction.

5.6.4.5.6 Batteries shall be prepared for use according to the battery manufacturer's instructions.

5.6.4.6* Automatic Battery Charger. In addition to the prime mover– (engine-) driven charger required in 5.6.3.6.1, a battery charger(s), as required in Table 5.6.4.2, shall be supplied for maintaining a charge on both the starting and control battery unit.

5.6.4.7 All chargers shall include the following characteristics, which are to be accomplished without manual intervention (i.e., manual switch or manual tap changing):

(1) At its rated voltage, the charger shall be capable of delivering energy into a fully discharged battery unit without damaging the battery.
(2) The charger shall be capable of returning the fully discharged battery to 100 percent of its ampere-hour rating within the time specified in Table 5.6.4.2, item (f).
(3) As specified in Table 5.6.4.2, item (e), meters with an accuracy within 5 percent of range shall be furnished.

(4) The charger shall be permanently marked with the following:
   (a) Allowable range of battery unit capacity
   (b) Nominal output current and voltage
   (c) Sufficient battery-type data to allow replacement batteries to be obtained
(5) The battery charger output and performance shall be compatible with the batteries furnished.

5.6.5 Control Functions.

5.6.5.1 A control panel shall be provided and shall contain the following:

(1) Automatic remote start capability
(2) "Run-off-automatic" switch
(3) Shutdowns as required by 5.6.5.2(3)
(4) Alarms as required by 5.6.5.2(4)
(5) Controls as required by 5.6.5.2(5)

5.6.5.2 Where a control panel is mounted on the energy converter, it shall be mounted by means of antivibration shock mounts, if required, to maximize reliability. An automatic control and safety panel shall be a part of the EPS containing the following equipment or possess the following characteristics, or both:

(1) Cranking control equipment to provide the complete cranking cycle described in 5.6.4.2 and required by Table 5.6.4.2
(2) Panel-mounted control switch(es) marked "run–off–automatic" to perform the following functions:
   (a) Run: Manually initiate, start, and run prime mover
   (b) Off: Stop prime mover or reset safeties, or both
   (c) Automatic: Allow prime mover to start by closing a remote contact and stop by opening the remote contact
(3) Controls to shut down and lock out the prime mover under any of the following conditions:
   (a) Failing to start after specified cranking time
   (b) Overspeed
   (c) Low lubricating-oil pressure
   (d) High engine temperature (An automatic engine shutdown device for high lubricating-oil temperature shall not be required.)
   (e) Operation of remote manual stop station
(4) Individual alarm indication to annunciate any of the conditions listed in Table 5.6.5.2 and with the following characteristics:
   (a) Battery powered
   (b) Visually indicated
   (c) Have additional contacts or circuits for a common audible alarm that signals locally and remotely when any of the itemized conditions occurs
   (d) Have a lamp test switch(es) to test the operation of all alarm lamps
(5) Controls to shut down the prime mover upon removal of the initiating signal or manual emergency shutdown
(6) The ac instruments listed in 5.6.9.9

5.6.5.3 Engines equipped with a maintaining shutdown device (air shutdown damper) shall have a set of contacts that monitor the position of this device, with local alarm indication and remote annunciation in accordance with Table 5.6.5.2.

5.6.5.4 The control panel in 5.6.5.2(4) shall be specifically approved for either a Level 1 or a Level 2 EPS consistent with the installation.

5.6.5.5 The cranking cycle shall be capable of being initiated by any of the following:

(1) Manual start initiation as specified in 5.6.5.2(2)(a).
(2) Loss of normal power at any automatic transfer switch (ATS) considered a part of the EPSS. Prime mover shall start upon closing of a remote switch or contacts and shall stop, after appropriate time delays, when switch or contacts are opened.
(3) Clock exerciser located in an ATS or in the control panel.
(4) Manually operated (test) switch located in each ATS that simulates a loss of power and causes automatic starting and operation until this switch is reset, to cause the engine circuit to duplicate its functions in the same manner commercial power is restored after a true commercial power failure.

5.6.5.6* All installations shall have a remote manual stop station of a type to prevent inadvertent or unintentional operation located outside the room housing the prime mover, where so installed, or elsewhere on the premises where the prime mover is located outside the building.

5.6.5.6.1 The remote manual stop station shall be labeled.

5.6.6* Remote Controls and Alarms. A remote, common audible alarm shall be provided as specified in 5.6.5.2(4).

5.6.6.1 Alarms and annunciation shall be powered by the prime mover starting battery unless operational constraints make this impracticable. In that circumstance an alternate source from the EPS, such as a storage battery, UPS, or branch circuit supplied by the EPSS, shall be permitted.

5.6.6.2 The following annunciation shall be provided at a minimum:

(1) For Level 1 EPS, local annunciation and facility remote annunciation, or local annunciation and network remote annunciation
(2) For Level 2 EPS, local annunciation

5.6.6.3 For the purposes of defining the types of annunciation in 5.6.6.2, the following shall apply:

(1) Local annunciation is located on the equipment itself or within the same equipment room.
(2) Facility remote annunciation is located on site but not within the room where the equipment is located.
(3) Network remote annunciation is located off site.

5.6.6.4 An alarm-silencing means shall be provided, and the panel shall include repetitive alarm circuitry so that, after the audible alarm has been silenced, it reactivates after the fault condition has been cleared and has to be restored to its normal position to be silenced again.

5.6.6.5 In lieu of the requirement in 5.6.6.4, a manual alarm-silencing means shall be permitted that silences the audible alarm after the occurrence of the alarm condition, provided such means do not inhibit any subsequent alarms from sounding the audible alarm again without further manual action.

5.6.7 Prime Mover Cooling Systems. Cooling systems for prime movers shall be either forced-air or natural convection, liquid-cooled, or a combination thereof.

Table 5.6.5.2 Safety Indications and Shutdowns

	Level 1			Level 2		
Indicator Function (at Battery Voltage)	**CV**	**S**	**RA**	**CV**	**S**	**RA**
(a) Overcrank	X	X	X	X	X	O
(b) Low water temperature	X	NA	X	X	NA	O
(c) High engine temperature pre-alarm	X	NA	X	O	NA	NA
(d) High engine temperature	X	X	X	X	X	O
(e) Low lube oil pressure	X	X	X	X	X	O
(f) Overspeed	X	X	X	X	X	O
(g) Low fuel main tank	X	NA	X	O	NA	O
(h) Low coolant level	X	O	X	X	O	X
(i) EPS supplying load	X	NA	NA	O	NA	NA
(j) Control switch not in automatic position	X	NA	X	X	NA	X
(k) High battery voltage	X	NA	NA	O	NA	NA
(l) Low cranking voltage	X	NA	X	O	NA	O
(m) Low voltage in battery	X	NA	NA	O	NA	NA
(n) Battery charger ac failure	X	NA	NA	O	NA	NA
(o) Lamp test	X	NA	NA	X	NA	NA
(p) Contacts for local and remote common alarm	X	NA	X	X	NA	X
(q) Audible alarm silencing switch	NA	NA	X	NA	NA	O
(r) Low starting air pressure	X	NA	NA	O	NA	NA
(s) Low starting hydraulic pressure	X	NA	NA	O	NA	NA
(t) Air shutdown damper when used	X	X	X	X	X	O
(u) Remote emergency stop	NA	X	NA	NA	X	NA

CV: Control panel–mounted visual. S: Shutdown of EPS indication. RA: Remote audible. X: Required. O: Optional. NA: Not applicable.
Notes:
(1) Item (p) shall be provided, but a separate remote audible signal shall not be required when the regular work site in 5.6.6 is staffed 24 hours a day.
(2) Item (b) is not required for combustion turbines.
(3) Item (r) or (s) shall apply only where used as a starting method.
(4) Item (i) EPS ac ammeter shall be permitted for this function.
(5) All required CV functions shall be visually annunciated by a remote, common visual indicator.
(6) All required functions indicated in the RA column shall be annunciated by a remote, common audible alarm as required in 5.6.5.2(4).
(7) Item (g) on gaseous systems shall require a low gas pressure alarm.
(8) Item (b) shall be set at 11°C (20°F) below the regulated temperature determined by the EPS manufacturer as required in 5.3.1.

5.6.7.1 Forced-air-cooled diesel or otto cycle engines shall have an integral fan selected to cool the prime mover under full load conditions.

5.6.7.2 Liquid-cooled prime movers for Level 1 applications shall be arranged for closed-loop cooling and consist of one of the following types:

(1) Unit-mounted radiator and fan
(2) Remote radiator
(3) Heat exchanger (liquid-to-liquid)

5.6.7.3 Cooling systems shall prevent overheating of prime movers under conditions of highest anticipated ambient temperature at the installed elevation (above sea level) when fully loaded.

5.6.7.4* Power for fans and pumps on remote radiators and heat exchangers shall be supplied from a tap at the EPS output terminals or ahead of the first load circuit overcurrent protective device.

5.6.7.5 The secondary side of heat exchangers shall be a closed-loop cycle, that is, one that recycles the cooling agent.

5.6.7.6 The installed EPS cooling system shall be designed to cool the prime mover at full-rated load while operating in the particular installation circumstances of each EPS.

5.6.7.7 A full-load on-site test shall not result in activation of high-temperature pre-alarm or high-temperature shutdown.

5.6.7.8 For EPSS cooling systems requiring intermittent or continuous waterflow or pressure, or both, a utility, city, or other water supply service shall not be used.

5.6.7.9 The EPSS cooling system shall be permitted to use utility or city water for filling or makeup water.

5.6.7.10 Design of the EPS cooling system shall consider the following factors:

(1) Remote radiator or heat exchanger sizing
(2) Pipe sizing
(3) Pump sizing
(4) Sufficient shutoffs to isolate equipment to facilitate maintenance
(5) The need for and sizing of de-aeration and surge tanks
(6) Drain valves for cleaning and flushing the cooling system
(7) Type of flexible hoses between the prime mover and the cooling system piping

5.6.8 Prime Mover Exhaust Piping. Where applicable, the exhaust system shall include a muffler or silencer sized for the unit and a flexible exhaust section.

5.6.9 Generators, Exciters, and Voltage Regulators. Generators shall comply with Article 445 of *NFPA 70*, *National Electrical Code*, and with the requirements of 5.6.9.1 through 5.6.9.9.

5.6.9.1* The generator shall be of dripproof construction and have amortisseur windings.

5.6.9.2 The generator shall be suitable for the environmental conditions at the installation location.

5.6.9.3 The generator systems shall be factory tested as a unit to ensure operational integrity of all of the following:

(1) Generator
(2) Exciter
(3) Voltage regulator

5.6.9.4 EPS voltage output, or the output of the transformer immediately down-line from the EPS, at full load shall match the nominal voltage of the normal source at the transfer switch(es).

5.6.9.5 Exciters, where furnished, shall be of either the rotating type or the static type.

5.6.9.6 Voltage regulators shall be capable of responding to load changes to meet the system stability requirements of 5.6.9.8.

5.6.9.7 If the system stability requirements of 5.6.9.8 cannot be accomplished, anti-hunt provisions shall be included.

5.6.9.8 Generator system performance (i.e., prime mover, generator, exciter, and voltage regulator, as applicable when prototype tested as specified in 5.2.1.2) shall be as follows:

(1) Stable voltage and frequency at all loads shall be provided to full-rated loads.
(2) Values consistent with the user's needs for frequency droop and voltage droop shall be maintained.
(3) Voltage dip at the generator terminals for the maximum anticipated load change shall not cause disruption or relay dropout in the load.
(4) Frequency dip and restoration to steady state for any sudden load change shall not exceed the user's specified need.

5.6.9.9 The generator instrument panel for Level 1 applications shall contain the following:

(1) An ac voltmeter(s) for each phase or a phase selector switch
(2) An ac ammeter(s) for each phase or a phase selector switch
(3) A frequency meter
(4) A voltage-adjusting feature to allow ± 5 percent voltage adjustment

5.6.10 Miscellaneous Requirements.

5.6.10.1 Where applicable, the prime mover and generator shall be factory mounted on a common base, rigid enough to maintain the dynamic alignment of the rotating element of the system prior to shipment to the installation site.

5.6.10.2 A certification shall be supplied with the unit that verifies the torsional vibration compatibility of the rotating element of the prime mover and generator for the intended use of the energy converter.

5.6.10.3* Vibration isolators shall be furnished where necessary to minimize vibration transmission to the permanent structure.

5.6.10.4 The manufacturer of the EPS shall submit complete schematic, wiring, and interconnection diagrams showing all terminal and destination markings for all EPS equipment, as well as the functional relationship between all electrical components.

5.6.10.5 The energy converter supplier shall stipulate compliance and performance with this standard for the entire unit when installed.

5.6.10.6 Where requested, the short circuit current capability at the generator output terminals shall be furnished.

Chapter 6 Transfer Switch Equipment

6.1 General.

6.1.1* Switches shall transfer electric loads from one power source to another.

6.1.2* The electrical rating shall be sized for the total load that is designed to be connected.

6.1.3 Each switch shall be in a separate enclosure or compartment.

6.1.4 The switch, including all load current-carrying components, shall be listed for all load types to be served.

6.1.5 The switch, including all load current-carrying components, shall be designed to withstand the effects of available fault currents.

6.1.6* Where available, each switch shall be listed for emergency service as a completely factory-assembled and factory-tested apparatus. Medium voltage transfer of central plant or mechanical equipment not including life safety, emergency, or critical branch loads shall be permitted to be transferred by electrically interlocked medium voltage circuit breakers.

6.2 ATS Features.

6.2.1* General. Automatic transfer switches shall be capable of all of the following:

(1) Electrical operation and mechanical holding
(2) Transfer and retransfer of the load automatically
(3) Visual annunciation when “not-in-automatic”

6.2.2 Source Monitoring.

6.2.2.1* Undervoltage-sensing devices shall be provided to monitor all ungrounded lines of the primary source of power as follows:

(1) When the voltage on any phase falls below the minimum operating voltage of any load to be served, the transfer switch shall automatically initiate engine start and the process of transfer to the EPS.
(2)* When the voltage on all phases of the primary source returns to within specified limits for a designated period of time, the process of transfer back to primary power shall be initiated.

6.2.2.2 Both voltage-sensing and frequency-sensing equipment shall be provided to monitor one ungrounded line of the EPS.

6.2.2.3 Transfer to the EPS shall be inhibited until the voltage and frequency are within a specified range to handle loads to be served.

6.2.2.3.1 Sensing equipment shall not be required in the transfer switch, provided it is included with the engine control panel.

6.2.2.3.2 Frequency-sensing equipment shall not be required for monitoring the public utility source where used as an EPS, as permitted by 5.1.3.

6.2.3* Interlocking. Mechanical interlocking or an approved alternate method shall prevent the inadvertent interconnection of the primary power supply and the EPS, or any two separate sources of power.

6.2.4* Manual Operation. Instruction and equipment shall be provided for safe manual nonelectric transfer in the event the transfer switch malfunctions.

6.2.5* Time Delay on Starting of EPS. A time-delay device shall be provided to delay starting of the EPS. The timer shall prevent nuisance starting of the EPS and possible subsequent load transfer in the event of harmless momentary power dips and interruptions of the primary source.

6.2.6 Time Delay at Engine Control Panel. Time delays shall be permitted to be located at the engine control panel in lieu of in the transfer switches.

6.2.7 Time Delay on Transfer to EPS. An adjustable time-delay device shall be provided to delay transfer and sequence load transfer to the EPS to avoid excessive voltage drop when the transfer switch is installed for Level 1 use.

6.2.7.1 Time Delay Commencement. The time delay shall commence when proper EPS voltage and frequency are achieved.

6.2.7.2 Time Delay at Engine Control Panel. Time delays shall be permitted to be located at the engine control panel in lieu of in the transfer switches.

6.2.8* Time Delay on Retransfer to Primary Source. An adjustable time-delay device with automatic bypass shall be provided to delay retransfer from the EPS to the primary source of power and to allow the primary source to stabilize before retransfer of the load.

6.2.9 Time Delay Bypass If EPS Fails. The time delay shall be automatically bypassed if the EPS fails.

6.2.9.1 The transfer switch shall be permitted to be programmed for a manually initiated retransfer to the primary source to provide for a planned momentary interruption of the load.

6.2.9.2 If used, the arrangement in 6.2.9.1 shall be provided with a bypass feature to allow automatic retransfer in the event that the EPS fails and the primary source is available.

6.2.10 Time Delay on Engine Shutdown. A minimum time delay of 5 minutes shall be provided for unloaded running of the EPS prior to shutdown to allow for engine cooldown.

6.2.10.1 The minimum 5-minute delay shall not be required on small (15 kW or less) air-cooled prime movers.

6.2.10.2 A time-delay device shall not be required, provided it is included with the engine control panel, or if a utility feeder is used as an EPS.

6.2.11 Engine Generator Exercising Timer. A program timing device shall be provided to exercise the EPS as described in Chapter 8.

6.2.11.1 Transfer switches shall transfer the connected load to the EPS and immediately return to primary power automatically in case of an EPS failure.

6.2.11.2 Exercising timers shall be permitted to be located at the engine control panel in lieu of in the transfer switches.

6.2.11.3 A program timing device shall not be required in health care facilities that provide scheduled testing in accordance with NFPA 99, *Health Care Facilities Code*.

6.2.12 Test Switch. A test means shall be provided on each ATS that simulates failure of the primary power source and then transfers the load to the EPS.

6.2.13* Indication of Transfer Switch Position. Two pilot lights with identification nameplates or other approved position indicators shall be provided to indicate the transfer switch position.

6.2.14 Motor Load Transfer. Provisions shall be included to reduce currents resulting from motor load transfer if such currents could damage EPSS equipment or cause nuisance tripping of EPSS overcurrent protective devices.

6.2.15* Isolation of Neutral Conductors. Provisions shall be included for ensuring continuity, transfer, and isolation of the primary and the EPS neutral conductors wherever they are separately grounded to achieve ground-fault sensing.

6.2.16* Nonautomatic Transfer Switch Features. Switching devices shall be mechanically held and shall be operated by direct manual or electrical remote manual control.

6.2.16.1 Interlocking. Reliable mechanical interlocking or an approved alternate method shall prevent the inadvertent interconnection of the primary power source and the EPS.

6.2.16.2 Indication of Transfer Switch Position. Two pilot lights with identification nameplates or other approved position indicators shall be provided to indicate the switch position.

6.3 Load Switching (Load Shedding). When two or more engine generator sets are paralleled for emergency power, the paralleled system shall be arranged to inhibit connection of EPS-damaging loads.

6.3.1 Each transfer switch shall have a continuous current rating and interrupting rating for all classes of loads to be served.

6.3.2 The transfer switch shall be capable of withstanding the available fault current at the point of installation.

6.3.3 The transfer of loads to the EPS shall be sequenced as follows:

(1) First-priority loads shall be switched to the emergency bus upon sensing the availability of emergency power on the bus.
(2) Each time an additional engine generator set is connected to the bus, a remaining load shall be connected in

order of priority until all emergency loads are connected to the bus.

(3) The system shall be designed so that, upon failure of one or more engine generator sets, the load is automatically reduced, starting with the load of least priority and proceeding in ascending priority, so that the last load affected is the highest-priority load.

6.4 Bypass-Isolation Switches.

6.4.1 Bypassing and Isolating Transfer Switches. Bypass-isolation switches shall be permitted for bypassing and isolating the transfer switch and shall be installed in accordance with 6.4.2, 6.4.3, and 6.4.4.

6.4.2 Bypass-Isolation Switch Rating. The bypass-isolation switch shall have a continuous current rating and a current rating compatible with that of the associated transfer switch.

6.4.3* Bypass-Isolation Switch Classification. Each bypass-isolation switch shall be listed for emergency electrical service as a completely factory-assembled and factory-tested apparatus.

6.4.4* Operation. With the transfer switch isolated or disconnected, the bypass-isolation switch shall be designed so it can function as an independent nonautomatic transfer switch and allow the load to be connected to either power source.

6.4.5 Reconnection of Transfer Switch. Reconnection of the transfer switch shall be possible without a load interruption greater than the maximum time, in seconds, specified by the type of system.

6.5 Protection.

6.5.1* General. The overcurrent protective devices in the EPSS shall be coordinated to optimize selective tripping of the circuit overcurrent protective devices when a short circuit occurs.

6.5.2 Short Circuit Current. The maximum available short circuit current from both the utility source and the emergency energy source shall be evaluated for the ability to satisfy this coordination capability.

6.5.3* Overcurrent Protective Device Rating. The overcurrent protective device shall have an interrupting rating equal to or greater than the maximum available short circuit current at its location.

6.5.4 Accessibility. Overcurrent devices in EPSS circuits shall be accessible to authorized persons only.

Chapter 7 Installation and Environmental Considerations

7.1 General.

7.1.1* This chapter shall establish minimum requirements and considerations relative to the installation and environmental conditions that have an effect on the performance of the EPSS equipment such as the following:

(1) Geographic location
(2) Building type
(3) Classification of occupancy
(4) Hazard of contents

7.1.2* Minimizing the probability of equipment or cable failure within the EPSS shall be a design consideration to reduce the disruption of loads served by the EPSS.

7.1.3 The EPSS equipment shall be installed as required to meet the user's needs and to be in accordance with all of the following:

(1) This standard
(2) The manufacturer's specifications
(3) The authority having jurisdiction

7.1.4 EPSS equipment installed for the various levels of service defined in this standard shall be designed and assembled for such service.

7.1.5 When the normal power source is not available, the EPS shall be permitted to serve optional loads other than system loads, provided that the EPS has adequate capacity or automatic selective load pickup and load shedding are provided as needed to ensure adequate power to (1) the Level 1 loads, (2) the Level 2 loads, and (3) the optional loads, in that order of priority. When normal power is available, the EPS shall be permitted to be used for other purposes such as peak load shaving, internal voltage control, load relief for the utility providing normal power, or cogeneration.

7.2 Location.

7.2.1 Indoor EPS Installations. The EPS shall be installed in a separate room for Level 1 installations.

7.2.1.1 The EPS room shall be separated from the rest of the building by construction with a 2-hour fire resistance rating.

7.2.1.2 EPSS equipment shall be permitted to be installed in the EPS room.

7.2.1.3 No other equipment, including architectural appurtenances, except those that serve this space, shall be permitted in the EPS room.

7.2.2 Outdoor EPS Installations.

7.2.2.1 The EPS shall be installed in a suitable enclosure located outside the building and capable of resisting the entrance of snow or rain at a maximum wind velocity as required by local building codes.

7.2.2.2 EPSS equipment shall be permitted to be installed in the EPS enclosure.

7.2.2.3 No other equipment, including architectural appurtenances, except those that serve this space, shall be permitted in the EPS enclosure.

7.2.3* Level 1 EPSS equipment shall not be installed in the same room with the normal service equipment, where the service equipment is rated over 150 volts to ground and equal to or greater than 1000 amperes.

7.2.4* The rooms, enclosures, or separate buildings housing Level 1 or Level 2 EPSS equipment shall be designed and located to minimize damage from flooding, including that caused by the following:

(1) Flooding resulting from fire fighting
(2) Sewer water backup
(3) Other disasters or occurrences

7.2.5* Minimizing the possibility of damage resulting from interruptions of the emergency source shall be a design consideration for EPSS equipment.

7.2.6 The EPS equipment shall be installed in a location that permits ready accessibility and a minimum of 0.9 m (36 in.)

from the skid rails' outermost point in the direction of access for inspection, repair, maintenance, cleaning, or replacement. This requirement shall not apply to units in outdoor housings.

7.2.7 Design considerations shall minimize the effect of the failure of one energy converter on the continued operation of other units.

7.3 Lighting.

7.3.1 The Level 1 or Level 2 EPS equipment location(s) shall be provided with battery-powered emergency lighting. This requirement shall not apply to units located outdoors in enclosures that do not include walk-in access.

7.3.2 The emergency lighting charging system and the normal service room lighting shall be supplied from the load side of the transfer switch.

7.3.3* The minimum average horizontal illumination provided by normal lighting sources in the separate building or room housing the EPS equipment for Level 1 shall be 32.3 lux (3.0 ft-candles) measured at the floor level, unless otherwise specified by a requirement recognized by the authority having jurisdiction.

7.4 Mounting.

7.4.1 Rotating energy converters shall be installed on solid foundations to prohibit sagging of fuel, exhaust, or lubricating-oil piping and damage to parts resulting in leakage at joints.

7.4.1.1 Such foundations or structural bases shall raise the engine at least 150 mm (6 in.) above the floor or grade level and be of sufficient elevation to facilitate lubricating-oil drainage and ease of maintenance.

7.4.2 Foundations shall be of the size (mass) and type recommended by the energy converter manufacturer.

7.4.3 Where required to prevent transmission of vibration during operation, the foundation shall be isolated from the surrounding floor or other foundations, or both, in accordance with the manufacturer's recommendations and accepted structural engineering practices.

7.4.4 The EPS shall be mounted on a fabricated metal skid base of the type that shall resist damage during shipping and handling. After installation, the base shall maintain alignment of the unit during operation.

7.5* Vibration. Vibration isolators, as recommended by the manufacturer of the EPS, shall be installed either between the rotating equipment and its skid base or between the skid base and the foundation or inertia base.

7.6* Noise. Design shall include consideration of noise control regulations.

7.7 Heating, Cooling, and Ventilating.

7.7.1* With the EPS running at rated load, ventilation airflow shall be provided to limit the maximum air temperature in the EPS room or the enclosure housing the unit to the maximum ambient air temperature required by the EPS manufacturer.

7.7.1.1 Consideration shall be given to all the heat emitted to the EPS equipment room by the energy converter, uninsulated or insulated exhaust pipes, and other heat-producing equipment.

7.7.2 Air shall be supplied to the EPS equipment for combustion.

7.7.2.1* For EPS supplying Level 1 EPSS, ventilation air shall be supplied directly from a source outside the building by an exterior wall opening or from a source outside the building by a 2-hour fire-rated air transfer system.

7.7.2.2 For EPS supplying Level 1 EPSS, discharge air shall be directed outside the building by an exterior wall opening or to an exterior opening by a 2-hour fire-rated air transfer system.

7.7.2.3 Fire dampers, shutters, or other self-closing devices shall not be permitted in ventilation openings or ductwork for supply or return/discharge air to EPS equipment for Level 1 EPSS.

7.7.3 Ventilation air supply shall be from outdoors or from a source outside the building by an exterior wall opening or from a source outside the building by a 2-hour fire-rated air transfer system.

7.7.4 Ventilation air shall be provided to supply and discharge cooling air for radiator cooling of the EPS when running at rated load.

7.7.4.1 Ventilation air supply and discharge for radiator-cooled EPS shall have a maximum static restriction of 125 Pa (0.5 in. of water column) in the discharge duct at the radiator outlet.

7.7.4.2 Radiator air discharge shall be ducted outdoors or to an exterior opening by a 2-hour rated air transfer system.

7.7.5 Motor-operated dampers, when used, shall be spring operated to open and motor closed. Fire dampers, shutters, or other self-closing devices shall not be permitted in ventilation openings or ductwork for supply or return/discharge air to EPS equipment for Level 1 EPSS.

7.7.6 Units housed outdoors shall be heated as specified in 5.3.5.

7.7.7 Design of the heating, cooling, and ventilation system for the EPS equipment room shall include provision for factors including, but not limited to, the following:

(1) Heat
(2) Cold
(3) Dust
(4) Humidity
(5) Snow and ice accumulations around housings
(6) Louvers
(7) Remote radiator fans
(8) Prevailing winds blowing against radiator fan discharge air

7.8 Installed EPS Cooling System.

7.8.1 Makeup water hose bibs and floor drains, where required by other codes and standards, shall be installed in EPS equipment rooms.

7.8.2 Where duct connections are used between the prime mover radiator and air-out louvers, the ducts shall be connected to the prime movers by means of flexible sections.

7.9 Fuel System.

7.9.1 Fuel tanks shall be sized to accommodate the specific EPS class.

7.9.1.1* All fuel tanks and systems shall be installed and maintained in accordance with NFPA 30, *Flammable and Combustible Liquids Code*; NFPA 37, *Standard for the Installation and Use of Stationary Combustion Engines and Gas Turbines*; NFPA 54, *National Fuel Gas Code*; and NFPA 58, *Liquefied Petroleum Gas Code*.

7.9.1.2* Fuel system design shall provide for a supply of clean fuel to the prime mover.

7.9.1.3 Tanks shall be sized so that the fuel is consumed within the storage life, or provisions shall be made to remediate fuel that is stale or contaminated or to replace stale or contaminated fuel with clean fuel.

7.9.2 Fuel tanks shall be close enough to the prime mover for the fuel lift (suction head) of the prime mover fuel pump to meet the fuel system requirements, or a fuel transfer pump and day tank shall be provided.

7.9.2.1 If the engine manufacturer's fuel pump static head pressure limits are exceeded when the level of fuel in the tank is at a maximum, a day tank shall be utilized.

7.9.3 Fuel piping shall be of compatible metal to minimize electrolysis and shall be properly sized, with vent and fill pipes located to prevent entry of groundwater or rain into the tank.

7.9.3.1* Galvanized fuel lines shall not be used.

7.9.3.2 Approved flexible fuel lines shall be used between the prime mover and the fuel piping.

7.9.4 Day tanks on diesel systems shall be installed below the engine fuel return elevation.

7.9.4.1 The return line to the day tank shall be below the fuel return elevation.

7.9.4.2 Gravity fuel oil return lines between the day tank and the main supply tank shall be sized to handle the potential fuel flow and shall be free of traps so that fuel can flow freely to the main tank.

7.9.5 Integral tanks of the following capacities shall be permitted inside or on roofs of structures, or as approved by the authority having jurisdiction:

(1) Maximum of 2498 L (660 gal) diesel fuel
(2) Maximum of 95 L (25 gal) gasoline fuel

7.9.6* The fuel supply for gas-fueled and liquid-fueled prime movers shall be installed in accordance with applicable standards.

7.9.7* Where the gas supply is connected to the building gas supply system, it shall be connected on the supply side of the main gas shutoff valve and marked as supplying an emergency generator.

7.9.8 The building's main gas shutoff valve shall be marked or tagged to indicate the existence of the separate EPS shutoff valve.

7.9.9 The fuel supply for gas-fueled and liquid-fueled prime movers shall be designed to meet the demands of the prime mover for all of the following factors:

(1) Sizing of fuel lines
(2) Valves, including manual shutoff
(3) Battery-powered fuel solenoids
(4) Gas regulators
(5) Regulator vent piping
(6) Flexible fuel line section
(7) Fuel line filters
(8) Fuel vaporizers (LP-Gas)
(9) Ambient temperature effect of fuel tank vaporization rates of LP-Gas where applicable

7.9.10 The fuel storage and supply lines for an EPSS shall be in accordance with this standard or with the specific authority having jurisdiction, or both.

7.9.11 All manual fuel system valves shall be of the indicating type.

7.9.12 Listed generator subbase secondary containment fuel tanks of 2498 L (660 gal) capacity and below shall be permitted to be installed outdoors or indoors without diking or remote impounding.

7.9.12.1 A minimum clearance of 0.9 m (36 in.) shall be maintained on all sides.

7.9.13 Automatically actuated valves shall not be permitted in the fuel oil supply or fuel oil return lines.

7.10 Exhaust System.

7.10.1 The exhaust system equipment and installation, including piping, muffler, and related accessories, shall be in accordance with NFPA 37, *Standard for the Installation and Use of Stationary Combustion Engines and Gas Turbines*, and other applicable standards.

7.10.2 Exhaust system installation shall be gastight to prevent exhaust gas fumes from entering inhabited rooms or buildings and terminate in such a manner that toxic fumes cannot reenter a building or structure, particularly through windows, air ventilation inlets, or the engine air-intake system.

7.10.3* Exhaust piping shall be connected to the prime mover by means of a flexible connector and shall be independently supported thereafter so that no damaging weight or stress is applied to the engine exhaust manifold or turbocharger.

7.10.3.1 A condensate trap and drain valve shall be provided at the low point(s) of the piping unless the piping is self-draining.

7.10.3.2 Design consideration shall be given to thermal expansion and the resultant movement of the piping.

7.10.3.3 For reciprocating engines, mufflers shall be placed as close as practicable to the engine, in a horizontal position if possible.

7.10.3.4 An approved thimble(s) shall be used where exhaust piping passes through combustible walls or partitions.

7.10.3.5 For reciprocating engines, the piping shall terminate in any of the following:

(1) Rain cap
(2) Tee
(3) Ell, pointing downwind from the prevailing wind
(4) Vertically upward-oriented stack with suitable provisions for trapping and draining rain and snow water

7.10.3.6 Design consideration shall be given to the potential heat effect due to proximity to all of the following:

(1) Conduit runs
(2) Fuel piping
(3) Lighting fixtures

7.10.3.7 Design consideration shall be given to insulating the engine exhaust systems in buildings after the flexible section.

7.10.4 For maximum efficiency, operation economy, and prevention of engine damage, the exhaust system shall be designed to eliminate excessive backpressure on the engine by properly selecting, routing, and installing the piping size, connections, and muffler.

7.10.4.1 Exhaust systems shall be installed to ensure satisfactory EPS operation and meet the requirements of the manufacturer.

7.11 Protection.

7.11.1 The room in which the EPS equipment is located shall not be used for other purposes that are not directly related to the EPS. Parts, tools, and manuals for routine maintenance and repair shall be permitted to be stored in the EPS room.

7.11.2* Where fire suppression systems are installed in EPS equipment rooms or separate buildings, the following systems shall not be used:

(1) Carbon dioxide or halon systems, unless prime mover combustion air is taken from outside the structure
(2) An automatic dry chemical system, unless the manufacturers of the EPS certify that the dry chemical system cannot damage the EPS system, hinder its operation, or reduce its output

7.11.3 Where the EPS rooms or separate buildings are equipped with fire detection systems, the installation shall be in accordance with *NFPA 72, National Fire Alarm and Signaling Code*.

7.11.4 Where outdoor and/or rooftop Level 1 EPS installations are required to be protected from lightning, the lightning protection system(s) shall be installed in accordance with NFPA 780, *Standard for the Installation of Lightning Protection Systems*.

7.11.5* In recognized seismic risk areas, EPS and EPSS components, such as electrical distribution lines, water distribution lines, fuel distribution lines, and other components that serve the EPS, shall be designed to minimize damage from earthquakes and to facilitate repairs if an earthquake occurs.

7.11.6* For systems in seismic risk areas, the EPS, transfer switches, distribution panels, circuit breakers, and associated controls shall be capable of performing their intended function during and after being subjected to the anticipated seismic shock.

7.12 Distribution.

7.12.1 The distribution and wiring systems within EPSS shall be installed in accordance with *NFPA 70, National Electrical Code*.

7.12.2 When EPSSs are installed in health care facilities, the installation of the EPSS shall also be in compliance with NFPA 99, *Health Care Facilities Code*.

7.12.3 The wiring between the EPS output terminals and the first distribution overcurrent protective device terminals within the EPSS shall be located at a minimal distance to ensure system reliability and safety.

7.12.4 If the conduit's point of attachment to the EPS is on the forcing function side of the EPS vibration isolation system, a flexible conduit section(s) shall be installed between the EPS unit(s) and any of the following, so attached:

(1) The transfer switch
(2) The control and annunciator wiring
(3) Any accessory supply wiring such as jacket water heaters

7.12.4.1 Stranded wire of adequate size shall be used to minimize breakage due to vibration.

7.12.4.2 Bushings shall be installed to protect wiring from abrasion with conduit terminations.

7.12.5 All ac-powered support and accessory equipment necessary to the operation of the EPS shall be supplied from the load side of the ATSs, or the output terminals of the EPS, ahead of the main EPS overcurrent protection to ensure continuity of the EPSS operation and performance.

7.12.6 The starting battery units shall be located next to the prime mover starter to minimize voltage drop.

7.12.6.1 Battery cables shall be sized to minimize voltage drop in accordance with the manufacturer's recommendations and accepted engineering practices.

7.12.6.2 Battery charger output wiring shall be permanently connected to the primary side of the starter solenoid (positive) and the EPS frame (negative), or other grounding location.

7.13 Installation Acceptance.

7.13.1 Upon completion of the installation of the EPSS, the EPS shall be tested to ensure conformity to the requirements of the standard with respect to both power output and function.

7.13.2 An on-site acceptance test shall be conducted as a final approval test for all EPSSs.

7.13.2.1 For new Level 1 installations, the EPSS shall not be considered as meeting this standard until the acceptance tests have been conducted and test requirements met.

7.13.2.2 The test shall be conducted after completion of the installation with all EPSS accessory and support equipment in place and operating.

7.13.3 The authority having jurisdiction shall be given advance notification of the time at which the acceptance test is to be performed so that the authority can witness the test.

7.13.4 The EPSS shall perform within the limits specified in this standard.

7.13.4.1 The on-site installation acceptance test shall be conducted in accordance with 7.13.4.1.1 through 7.13.4.1.4.

7.13.4.1.1* In a new and unoccupied building or facility, with the prime mover in a cold start condition and the emergency load at operating level, a normal power failure shall be initiated by opening all switches or circuit breakers supplying the normal power to the building or facility.

7.13.4.1.2* In an existing occupied building or facility, with the prime mover in a cold start condition and the emergency load at operating level, a normal power failure shall be simulated by operating at least one transfer switch test function or initiated by opening all switches or breakers supplying normal power to all ATSs that are part of the EPSS being commissioned by this initial acceptance test.

7.13.4.1.3 When the EPSS consists of paralleled EPSs, the system control function for paralleling and load shedding shall be verified in accordance with system design documentation.

7.13.4.1.4 The tests conducted in accordance with 7.13.4.1.1 and 7.13.4.1.2 shall be performed in accordance with (1) through (12).

(1) When the EPSS consists of paralleled EPSs, the quantity of EPSs intended to be operated simultaneously shall be tested simultaneously with building load for the test period identified in 7.13.4.1.4(10).
(2) The test load shall be all loads that are served by the EPSS. There is no minimum loading requirement for this portion of the test.
(3) The time delay on start shall be observed and recorded.
(4) The cranking time until the prime mover starts and runs shall be observed and recorded.
(5) The time taken to reach operating speed shall be observed and recorded.
(6)* The engine start function shall be confirmed by verifying operation of the initiating circuit of all transfer switches supplying EPSS loads.
(7) The time taken to achieve a steady-state condition with all switches transferred to the emergency position shall be observed and recorded.
(8) The voltage, frequency, and amperes shall be recorded.
(9) Where applicable, the prime mover oil pressure and water temperature shall be recorded.
(10) The load test with building load, or other loads that simulate the intended load as specified in Section 5.4, shall be continued for not less than 1.5 hours, and the run time shall be recorded.
(11) When normal power is restored to the building or facility, the time delay on retransfer to normal power for each switch with a minimum setting of 5 minutes shall be recorded.
(12) The time delay on the prime mover cooldown period and shutdown shall be recorded.

7.13.4.2 After completion of the test performed in 7.13.4.1, the prime mover shall be allowed to cool for not less than 5 minutes.

7.13.4.3* A load shall be applied for a 2-hour, full-load test. The building load shall be permitted to serve as part or all of the load, supplemented by a load bank of sufficient size to provide a load equal to 100 percent of the nameplate kW rating of the EPS, less applicable derating factors for site conditions.

7.13.4.3.1* This full-load test shall be initiated after the test specified in 7.13.4.1.4 by any method that starts the prime mover and, upon reaching rated rpm, picks up not less than 30 percent of the nameplate kW rating for the first 30 minutes, not less than 50 percent of the nameplate kW rating for the next 30 minutes, and 100 percent of the nameplate kW rating for the next 60 minutes, less applicable derating factors for site conditions.

7.13.4.3.2 A unity power factor shall be permitted for on-site testing, provided that rated load tests at the rated power factor have been performed by the manufacturer of the EPS prior to shipment.

7.13.4.3.3 Where the EPS is a paralleled multi-unit EPS, each unit shall be permitted to be tested individually at its rating.

7.13.4.3.4 The data specified in 7.13.4.1.4(4), 7.13.4.1.4(5), and 7.13.4.1.4(7) shall be recorded at first load acceptance of the test period identified in 7.13.4.1.4(10).

7.13.4.3.5 The data specified in 7.13.4.1.4(8) and 7.13.4.1.4(9) shall be recorded at first load acceptance and every 15 minutes thereafter until the completion of the test period identified in 7.13.4.1.4(10).

7.13.4.4 Any method recommended by the manufacturer for the cycle crank test shall be utilized to prevent the prime mover from running.

7.13.4.4.1 The control switch shall be set at “run” to cause the prime mover to crank.

7.13.4.4.2 The complete crank/rest cycle specified in 5.6.4.2 and Table 5.6.4.2 shall be observed.

7.13.4.4.3 The battery charge rate shall be recorded at 5-minute intervals for the first 15 minutes or until charge rate stabilization.

7.13.4.5 All safeties specified in 5.6.5 and 5.6.6 shall be tested on site as recommended by the manufacturer.

Exception: It shall be permitted for the manufacturer to test and document overcrank, high engine temperature, low lube oil pressure and overspeed safeties prior to shipment.

7.13.4.6 Items (1) through (4) shall be made available to the authority having jurisdiction at the time of the acceptance test:

(1) Evidence of the prototype test as specified in 5.2.1.2 (for Level 1 systems)
(2) A certified analysis as specified in 5.6.10.2
(3) A letter of compliance as specified in 5.6.10.5
(4) A manufacturer’s certification of a rated load test at rated power factor with the ambient temperature, altitude, and fuel grade recorded

Chapter 8 Routine Maintenance and Operational Testing

8.1* General.

8.1.1 The routine maintenance and operational testing program shall be based on all of the following:

(1) Manufacturer's recommendations
(2) Instruction manuals
(3) Minimum requirements of this chapter
(4) The authority having jurisdiction

8.1.2 Consideration shall be given to temporarily providing a portable or alternate source whenever the emergency generator is out of service and the criteria set forth in Section 4.3 cannot be met.

8.2* Manuals, Special Tools, and Spare Parts.

8.2.1 At least two sets of instruction manuals for all major components of the EPSS shall be supplied by the manufacturer(s) of the EPSS and shall contain the following:

(1) A detailed explanation of the operation of the system
(2) Instructions for routine maintenance
(3) Detailed instructions for repair of the EPS and other major components of the EPSS
(4) An illustrated parts list and part numbers

(5) Illustrated and schematic drawings of electrical wiring systems, including operating and safety devices, control panels, instrumentation, and annunciators

8.2.2 For Level 1 systems, instruction manuals shall be kept in a secure, convenient location, one set near the equipment, and the other set in a separate location.

8.2.3 Special tools and testing devices necessary for routine maintenance shall be available for use when needed.

8.2.4 Replacement for parts identified by experience as high mortality items shall be maintained in a secure location(s) on the premises.

8.2.4.1 Consideration shall be given to stocking spare parts as recommended by the manufacturer.

8.3 Maintenance and Operational Testing.

8.3.1* The EPSS shall be maintained to ensure to a reasonable degree that the system is capable of supplying service within the time specified for the type and for the time duration specified for the class.

8.3.2 A routine maintenance and operational testing program shall be initiated immediately after the EPSS has passed acceptance tests or after completion of repairs that impact the operational reliability of the system.

8.3.2.1 The operational test shall be initiated at an ATS and shall include testing of each EPSS component on which maintenance or repair has been performed, including the transfer of each automatic and manual transfer switch to the alternate power source, for a period of not less than 30 minutes under operating temperature.

8.3.3 A written schedule for routine maintenance and operational testing of the EPSS shall be established.

8.3.4* Transfer switches shall be subjected to a maintenance and testing program that includes all of the following operations:

(1) Checking of connections
(2) Inspection or testing for evidence of overheating and excessive contact erosion
(3) Removal of dust and dirt
(4) Replacement of contacts when required

8.3.5* Paralleling gear shall be subject to an inspection, testing, and maintenance program that includes all of the following operations:

(1) Checking connections
(2) Inspecting or testing for evidence of overheating and excessive contact erosion
(3) Removing dust and dirt
(4) Replacing contacts when required
(5) Verifying that the system controls will operate as intended

8.3.6* Storage batteries, including electrolyte levels or battery voltage, used in connection with systems shall be inspected weekly and maintained in full compliance with manufacturer's specifications.

8.3.6.1 Maintenance of lead-acid batteries shall include the monthly testing and recording of electrolyte specific gravity. Battery conductance testing shall be permitted in lieu of the testing of specific gravity when applicable or warranted.

8.3.6.2 Defective batteries shall be replaced immediately upon discovery of defects.

8.3.7* A fuel quality test shall be performed at least annually using appropriate ASTM standards.

8.4 Operational Inspection and Testing.

8.4.1* EPSSs, including all appurtenant components, shall be inspected weekly and exercised under load at least monthly.

8.4.1.1 If the generator set is used for standby power or for peak load shaving, such use shall be recorded and shall be permitted to be substituted for scheduled operations and testing of the generator set, providing the same record as required by 8.3.4.

8.4.2* Diesel generator sets in service shall be exercised at least once monthly, for a minimum of 30 minutes, using one of the following methods:

(1) Loading that maintains the minimum exhaust gas temperatures as recommended by the manufacturer
(2) Under operating temperature conditions and at not less than 30 percent of the EPS standby nameplate kW rating

8.4.2.1 The date and time of day for required testing shall be decided by the owner, based on facility operations.

8.4.2.2 Equivalent loads used for testing shall be automatically replaced with the emergency loads in case of failure of the primary source.

8.4.2.3* Diesel-powered EPS installations that do not meet the requirements of 8.4.2 shall be exercised monthly with the available EPSS load and shall be exercised annually with supplemental loads at not less than 50 percent of the EPS nameplate kW rating for 30 continuous minutes and at not less than 75 percent of the EPS nameplate kW rating for 1 continuous hour for a total test duration of not less than 1.5 continuous hours.

8.4.2.4 Spark-ignited generator sets shall be exercised at least once a month with the available EPSS load for 30 minutes or until the water temperature and the oil pressure have stabilized.

8.4.2.4.1 The date and time of day for required testing shall be decided by the owner, based on facility operations.

8.4.2.4.2 Equivalent loads used for testing shall be automatically replaced with the emergency loads in case of failure of the primary source.

8.4.3 The EPS test shall be initiated by simulating a power outage using the test switch(es) on the ATSs or by opening a normal breaker. Opening a normal breaker shall not be required.

8.4.3.1* Where multiple ATSs are used as part of an EPSS, the monthly test initiating ATSs shall be rotated to verify the starting function on each ATS.

8.4.4 Load tests of generator sets shall include complete cold starts.

8.4.5 Time delays shall be set as follows:

(1) Time delay on start:
    (a) 1 second minimum
    (b) 0.5 second minimum for gas turbine units

(2) Time delay on transfer to emergency: no minimum required
(3) Time delay on restoration to normal: 5 minutes minimum
(4) Time delay on shutdown: 5 minutes minimum

8.4.6 Transfer switches shall be operated monthly.

8.4.6.1* The monthly test of a transfer switch shall consist of electrically operating the transfer switch from the primary position to the alternate position and then a return to the primary position.

8.4.6.2 The criteria set forth in Section 4.3 and in Table 4.1(b) shall not be required during the monthly testing of the EPSS. If the criteria are not met during the monthly test, a process shall be provided to annually confirm the capability of the system to comply with Section 4.3.

8.4.7* EPSS circuit breakers for Level 1 system usage, including main and feed breakers between the EPS and the transfer switch load terminals, shall be exercised annually with the EPS in the "off" position.

8.4.7.1 Circuit breakers rated in excess of 600 volts for Level 1 system usage shall be exercised every 6 months and shall be tested under simulated overload conditions every 2 years.

8.4.8 EPSS components shall be maintained and tested by qualified person(s).

8.4.9* Level 1 EPSS shall be tested at least once within every 36 months.

8.4.9.1 Level 1 EPSS shall be tested continuously for the duration of its assigned class *(see Section 4.2)*.

8.4.9.2 Where the assigned class is greater than 4 hours, it shall be permitted to terminate the test after 4 continuous hours.

8.4.9.3 The test shall be initiated by operating at least one transfer switch test function and then by operating the test function of all remaining ATSs, or initiated by opening all switches or breakers supplying normal power to all ATSs that are part of the EPSS being tested.

8.4.9.4 A power interruption to non-EPSS loads shall not be required.

8.4.9.5 The minimum load for this test shall be as specified in 8.4.9.5.1, 8.4.9.5.2, or 8.4.9.5.3.

8.4.9.5.1* For a diesel-powered EPS, loading shall be not less than 30 percent of the nameplate kW rating of the EPS. A supplemental load bank shall be permitted to be used to meet or exceed the 30 percent requirement.

8.4.9.5.2 For a diesel-powered EPS, loading shall be that which maintains the minimum exhaust gas temperatures as recommended by the manufacturer.

8.4.9.5.3 For spark-ignited EPSs, loading shall be the available EPSS load.

8.4.9.6 The test required in 8.4.9 shall be permitted to be combined with one of the monthly tests required by 8.4.2 and one of the annual tests required by 8.4.2.3 as a single test.

8.4.9.7* Where the test required in 8.4.9 is combined with the annual load bank test, the first 3 hours shall be at not less than the minimum loading required by 8.4.9.5 and the remaining hour shall be at not less than 75 percent of the nameplate kW rating of the EPS.

8.5 Records.

8.5.1 Records shall be created and maintained for all EPSS inspections, operational tests, exercising, repairs, and modifications.

8.5.2 Records required in 8.5.1 shall be made available to the authority having jurisdiction on request.

8.5.3 The record shall include the following:

(1) The date of the maintenance report
(2) Identification of the servicing personnel
(3) Notation of any unsatisfactory condition and the corrective action taken, including parts replaced
(4) Testing of any repair in the time recommended by the manufacturer

8.5.4 Records shall be retained for a period of time defined by the facility management or by the authority having jurisdiction.

Annex A Explanatory Material

Annex A is not a part of the requirements of this NFPA document but is included for informational purposes only. This annex contains explanatory material, numbered to correspond with the applicable text paragraphs.

A.1.1.4 See NFPA 111, *Standard on Stored Electrical Energy Emergency and Standby Power Systems.*

A.1.1.5(3) See Chapter 4.

A.1.4.1 Assignment of degree of reliability of the recognized EPSS, or equivalency of other methods, depends on the careful evaluation of the variables at each particular installation. One source of information on quantitative methods for assessing power system reliability is ANSI/IEEE 493, *Recommended Practice for the Design of Reliable Industrial and Commercial Power Systems.*

A.3.2.1 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

A.3.2.2 Authority Having Jurisdiction (AHJ). The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A.3.2.4 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A.3.3.1 Battery Certification. One such certifier of batteries is the American Association of Battery Manufacturers.

A.3.3.3 Emergency Power Supply (EPS). For rotary energy converters, components of an EPS include the following:

(1) Prime mover
(2) Cooling system
(3) Generator
(4) Excitation system
(5) Starting system
(6) Control system
(7) Fuel system
(8) Lube system, if required

The EPS includes all the related electrical and mechanical components of the proper size and/or capacity required for the generation of the required electrical power at the EPS output terminals.

A.3.3.4 Emergency Power Supply System (EPSS). See Annex B for diagrams of typical systems.

A.3.3.7.1 Valve-Regulated (VRLA). In VRLA batteries, the liquid electrolyte in the cells is immobilized in an absorptive glass mat (AGM cells or batteries) or by the addition of a gelling agent (gel cells or gelled batteries).

A.3.3.7.2 Vented (Flooded). Flooded lead-acid batteries might have a provision for the user to add water to the cell and are equipped with a flame-arresting vent that permits the escape of hydrogen and oxygen gas from the cell in a diffused manner such that a spark, or other ignition source, outside the cell will not ignite the gases inside the cell.

A.4.1 This standard specifies requirements for the EPSS as a complete functioning system in terms of types, classes, and levels. It is not the intent of this standard to recommend the EPSS most suitable for any given application. The terms *emergency power supply systems* and *standby power supply systems* as used in this standard include, but are not limited to, such terms as the following:

(1) Alternate power systems
(2) Standby power systems
(3) Legally required standby systems
(4) Alternate power sources

Since this standard specifies the installation, performance, maintenance, and test requirements in terms of types, classes, and levels, any of these terms might be appropriate for describing the application or use, depending on the need and the preference of the parties involved.

A.4.2 Selection of the class of the EPSS should take into account past outage records and fuel delivery problems due to weather, shortages, and other geographic and environmental conditions. Class "X" is a calculated value that usually represents between 48 and 96 hours of fuel for a Level 1 facility. Where the seismic design category is C, D, E, or F, as determined in accordance with ASCE/SEI 7, *Minimum Design Loads for Buildings and Other Structures,* the EPS supplying a Level 1 EPSS should be capable of a minimum 96 hours of operation without refueling if it is determined that EPS operation is necessary for this period.

A.4.4 It is recognized that EPSSs are utilized in many different locations and for many different purposes. The requirement for one application might not be appropriate for other applications.

A.4.4.1 Typically, Level 1 systems are intended to automatically supply illumination or power, or both, to critical areas and equipment in the event of failure of the primary supply or in the event of danger to elements of a system intended to supply, distribute, and control power and illumination essential for safety to human life. Other NFPA codes and standards, such as NFPA 20, *Standard for the Installation of Stationary Pumps for Fire Protection*, NFPA 99, *Health Care Facilities Code*, and NFPA *101*, *Life Safety Code*, provide specific requirements on where Level 1 systems are required.

Essential electrical systems can provide power for the following essential functions:

(1) Life safety illumination
(2) Fire detection and alarm systems
(3) Elevators
(4) Fire pumps
(5) Public safety communications systems
(6) Industrial processes where current interruption would produce serious life safety or health hazards
(7) Essential ventilating and smoke removal systems

A.4.4.2 Typically, Level 2 systems are intended to supply power automatically to selected loads (other than those classed as emergency systems) in the event of failure of the primary source.

Level 2 systems typically are installed to serve loads, such as the following, that, when stopped due to any interruption of the primary electrical supply, could create hazards or hamper rescue or fire-fighting operations:

(1) Heating and refrigeration systems
(2) Communications systems
(3) Ventilation and smoke removal systems
(4) Sewage disposal
(5) Lighting
(6) Industrial processes

A.4.4.3 The intent is not to prohibit the use of portable or alternate equipment whenever the permanent EPSS is out of service. *(See8.1.2.)*

A.4.4.4 It is important to recognize that an EPSS might react substantially differently from commercial power during transient and short circuit conditions due to the relatively small capacities of the EPSS compared to the primary commercial power source. *[See ANSI C 84.1, Standard for Electric Power Systems and Equipment — Voltage Ratings (60 hertz).]*

A.5.1.1 Examples of probability of interruption could include the following: earthquake, flood damage, or a demonstrated utility unreliability.

A.5.1.1(1) The grade of diesel fuel selected for use in a prime mover should be based on recommendations from the diesel engine manufacturer and ASTM D 975, *Standard Specification for Diesel Fuel Oils*. Where possible, the purchaser of fuel for the prime mover should specify a diesel fuel that does not contain biodiesel, which can accelerate the degradation of the diesel fuel if stored longer than 6 months. If diesel fuel is stored outside for long-term storage, it can be necessary to use a winter or arctic grade of diesel fuel or to take precautions such as insulating and heat-tracing fuel tanks and lines to ensure that fuel will flow to the prime mover under the coldest possible conditions.

A.5.1.1(2) ASTM D 1835, *Standard Specification for Liquified Petroleum (LP) Gases*, is a recognized standard covering LP-Gas.

A.5.1.1(3) ASTM does not have a standard specification for natural or synthetic gas. Industry generally uses pipeline specifications for natural gas quality.

A.5.1.3 On-site energy conversion is not restricted to rotating-type generating systems. Other types of continuous energy conversion systems can be used, including fuel-cell systems.

A.5.2.2 The following devices are typical of energy converters and energy sources that should be reviewed carefully as part of Level 1 EPSs:

(1) Motor-generator/engine
(2) Motor-generator/flywheel
(3) Steam turbine

Connection to the primary power source ahead of the primary source main service disconnect and a separate service should be excluded as a sole source of EPS.

A.5.4 It is recognized that in some installations, part or all of the output of the EPS might be used for peak shaving or part of the output might be used for driving nonessential loads during loss of the primary power source. Load shedding of these loads when the output of the energy converter is needed is one way of meeting the requirements of Section 5.4. The load should be reviewed to ascertain that load growth has not exceeded EPS capability.

A.5.5.2 The low-fuel alarm point for liquid-fueled engines is defined as the point when the main fuel tank contains insufficient fuel to meet the required full load operating hours and is the point at which this condition is signaled.

A.5.5.3 Consideration should be given to sizing tanks in order to meet minimum fuel supplier delivery requirements, particularly for small tanks. Consideration also should be given to oversizing tanks. More important, biodiesel blends up to B5 (ASTM D 975, *Standard Specification for Diesel Fuel Oils)* have much shorter shelf lives than conventional diesel fuel [ultra-low sulfur diesel (ULSD)] and can accelerate degradation processes, endangering the entire diesel fuel supply. Where fuel is stored for extended periods of time (e.g., more than 12 months), it is recommended that fuels be periodically pumped out and used in other services and replaced with fresh fuel. Prudent disaster management could require much larger on-site temporary or permanent fuel storage, and several moderate-sized tanks can be preferable to a single very large tank.

A.5.6.4.2 See Figure A.5.6.4.2 for a diagram of cranking cycles.

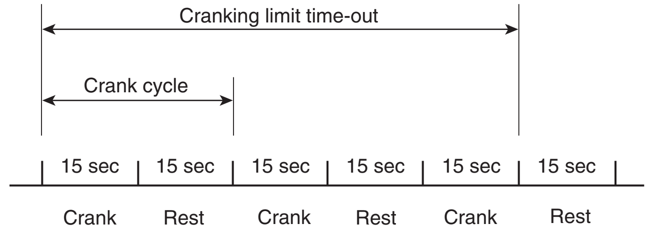

FIGURE A.5.6.4.2 Diagram of Cranking Cycles.

A.5.6.4.3 A battery unit is one or more batteries or a group of cells, a series, or a parallel series connected to provide the required battery unit voltage and capacity.

A.5.6.4.4 Cold-cranking amperes, or cranking performance, are the number of amperes a fully charged battery at -17.8°C (0°F) can continuously deliver for 30 seconds while maintaining 1.2 V per cell.

A.5.6.4.5.1 It is recommended that lead-acid starting batteries be replaced every 24 to 30 months.

A.5.6.4.6 It is intended that the battery charger be factory-built, adjusted, and approved for the specific type, construction, and capacity of the battery. For lead-acid batteries, the battery charger should be tested for the specific gravity, type, and concentration of grid alloys, such as high or low gravity, high or low antimony, calcium, or none.

A.5.6.5.6 For systems located outdoors, the manual shutdown should be located external to the weatherproof enclosure and should be appropriately identified.

A.5.6.6 The minimum "remote alarm annunciation" is to alert personnel at a constantly attended station somewhere on the site when the facility is in use as a Level 1 system. If the site is not continuously occupied, "network remote" should allow people at another site to know the operating status of the equipment.

The preferred method of remote annunciation is to notify personnel both somewhere on the site and at other locations via a network such as LAN, WAN, or Internet, including the ability to initiate auto-dial and send predefined text messages.

A.5.6.7.4 Adding remote parasitic equipment loads into the overall load to be supplied by the EPS is a factor that should be included in the overall EPSS design.

A.5.6.9.1 See ANSI/NEMA MG1, *Standard for Motors and Generators*, and ANSI/NEMA MG2, *Safety Standard and Guide for Selection, Installation and Use of Electric Motors and Generators.*

A.5.6.10.3 Where unusual vibration conditions are anticipated, adequate isolation treatment should be supplied.

A.6.1.1 Electrical switching is electrical equipment or devices used to do any or all of the following:

(1) Transfer connected electrical loads from one power source to another
(2) Perform load-switching functions
(3) Bypass, isolate, and test the transfer switch

A.6.1.2 Electrical protection equipment is sensing and overcurrent protective devices used to protect against damage due to fault or overload to conductors and equipment connected to the output of the emergency energy source, up to and including the load terminals of the transfer switch(es).

A.6.1.6 See Section 695.10 of *NFPA 70, National Electrical Code*, and Section 10.8 of NFPA 20, *Standard for the Installation of Stationary Pumps for Fire Protection*, for listing and installation requirements for transfer switches used with fire pumps.

A.6.2.1 For most applications in this standard, the automatic transfer switch (ATS) is used to transfer a load from a primary source of supply to an engine generator set.

An ATS might include circuit breakers, contactors, switches, or vacuum and solid-state power devices operating in conjunction with automatic-sensing and logic devices to perform the defined function.

A.6.2.2.1 Where special loads require more rapid detection of power loss, underfrequency monitoring also might be provided. Upon frequency decay below the lower limit necessary for proper operation of the loads, the transfer switch should automatically initiate transfer to the alternate source. *(See A.6.2.15.)*

A.6.2.2.1(2) See 6.2.5 and 6.2.7.

A.6.2.3 Certain installations might use automatic transfer switch equipment with momentary closed transition or soft-loading capabilities. This equipment should be applied with the approval of the local utility and authority having jurisdiction.

A.6.2.4 Authorized personnel should be available and familiar with manual operation of the transfer switch and should be capable of determining the adequacy of the alternate source of power prior to manual transfer.

A.6.2.5 For most applications, a nominal delay of 1 second is adequate. The time delay should be short enough so that the generator can start and be on line within the time specified for the type classification.

A.6.2.8 It is recommended that the timer for delay on retransfer to the primary source be set for 30 minutes. The 30-minute recommendation is to establish a "normalized" engine temperature when it is beneficial for the engine. *NFPA 70, National Electrical Code*, establishes a minimum time requirement of 15 minutes.

A.6.2.13 For maintenance purposes, consideration should be given to a transfer switch counter.

A.6.2.15 ATSs can be provided with accessory controls that provide a signal to operate remote motor controls that disconnect motors prior to transfer and to reconnect them after transfer when the residual voltage has been substantially reduced. Another method is to provide in-phase monitors within the ATS in order to prevent retransfer to the primary source until both sources are nearly synchronized. A third method is to use a programmed neutral position transfer switch. See Section 230.95 of *NFPA 70, National Electrical Code*.

A.6.2.16 Standards for nonautomatic transfer switches are similar to those for ATSs, as defined in 3.3.10.1 and 3.3.10.3, with the omission of automatic controls.

A.6.4.3 See Section 700.6 of *NFPA 70, National Electrical Code*.

A.6.4.4 Consideration should be given to the effect that load interruption could have on the load during maintenance and service of the transfer switch.

A.6.5.1 It is important that the various overcurrent devices be coordinated, as far as practicable, to isolate faulted circuits and to protect against cascading operation on short circuit faults. In many systems, however, full coordination is not practicable without using equipment that could be prohibitively costly or undesirable for other reasons. Primary consideration also should be given to prevent overloading of equipment by limiting the possibilities of large current inrushes due to instantaneous reestablishment of connections to heavy loads.

A.6.5.3 See 9.6.5 of NFPA 20, *Standard for the Installation of Stationary Pumps for Fire Protection.*

A.7.1.1 The performance of the EPS and the EPSS is dependent on many factors, one of which is correct initial installation, primarily as the installation relates to the location and environmental conditions. Although this standard is not intended to serve as a design standard for EPSS installation and environmental considerations, certain minimum standards are recognized as essential for successful startup and performance, safe operation, and utilization of the EPSS where required.

A.7.1.2 The environmental conditions to be considered in the EPSS design should include, but not be limited to, heating, ventilating, and air-conditioning systems; protection from floods, fire, vandalism, wind, earthquakes, lightning, and other similar or applicable environmental conditions common to geographic locations; and other factors affecting the location of the EPSS equipment.

The probability and frequency of power failures that do or can occur as a result of lightning, wind, and rain produced by thunderstorms, hurricanes, tornadoes, and similar weather conditions associated with the user's geographic location should be considered.

A.7.2.3 The intent of this requirement is to provide maximum fire protection to the most critical, high energy systems. Consideration should be given to the potential fire hazard when locating Level 2 EPSS equipment in the normal electrical service room, or to Level 1 systems below 1000 amperes and 150 volts to ground.

A.7.2.4 EPSS equipment should be located above known previous flooding elevations where possible.

A.7.2.5 When installing the EPSS equipment and related auxiliaries, environmental considerations should be given, particularly with regard to the installation of the fuel tanks *(see A.7.9.1.2)* and exhaust lines, or the EPS building, or both.

To protect against disruption of power in the facility, it is recommended that the transfer switch be located as close to the load as possible. The following are examples of external influences:

(1) Natural conditions such as the following:
    (a) Storms
    (b) Floods
    (c) Earthquakes
    (d) Tornadoes
    (e) Hurricanes
    (f) Lightning
    (g) Ice storms
    (h) Wind
    (i) Fire

(2) Human-caused conditions such as the following:
  (a) Vandalism
  (b) Sabotage
  (c) Other similar occurrences
(3) Material and equipment failures

For natural conditions, EPSS design should consider the "100-year storm" flooding level or the flooding level predicted by the Sea, Lake, and Overland Surges from Hurricanes (SLOSH) models for a Category 4 hurricane. For further information refer to FEMA 543 and FEMA 577, both dated August 11, 2013.

A.7.3.3 Where units housed outdoors are used, it is recommended that a flashlight or battery-powered light with a flexible cord be maintained in the housing.

A.7.5 Generally, integral rubber vibration isolators are used on the rotating energy converters, and spring-type or pad-type isolators are used on the larger energy converter units. In some cases, high deflection spring-type isolators should be used where a high degree of vibration attenuation is required. The EPS manufacturer should be consulted during consideration of the specific type of vibration control. Inertia bases should be considered where unusual vibration conditions are anticipated.

A.7.6 Generally, exhaust noises can be attenuated by using the proper mufflers. The mufflers used should be in accordance with the EPS manufacturer's recommendations. Depending on the degree of silencing required, the muffler should be rated accordingly for "commercial," "semicritical," and "critical" (high degree of silencing) service. To attenuate other noises, line-of-sight barriers having acoustical treatment or total acoustical enclosures can be used. The EPS should be installed away from critical areas.

A.7.7.1 During operation, EPS and related equipment reject considerable heat that needs to be removed by proper ventilation or air-cooling. In some cases, outdoor installations rely on natural air circulation, but enclosed installations need properly sized, properly positioned ventilation facilities, to prevent recirculation of cooling air. The optimum position of air-supply louvers and radiator air discharge is on opposite walls, both to the outdoors.

A.7.7.2.1 The ventilation calculation for an EPS should consider the following:

(1) Radiator airflow (when installed in the EPS room)
(2) Combustion airflow consumed by the engine
(3) Maximum potential ambient temperature of air entering the EPS room for ventilation
(4) Radiated heat load from the EPS
(5) Radiated heat load from EPS exhaust system whether it is insulated or not insulated
(6) Other heat loads in the room
(7) Maximum allowed airflow pressure drop through the ventilation supply into the room and through the ventilation discharged from the radiator

A.7.9.1.1 Cleaning and purging of flammable gas piping systems should be in accordance with NFPA 56, *Standard for Fire and Explosion Prevention During Cleaning and Purging of Flammable Gas Piping Systems*.

A.7.9.1.2 To optimize the long-term storage of fuels for prime movers, the fuel tanks should be kept cool and dry, and the tank as full as possible. Tanks that are subject to temperature variations can experience accelerated fuel degradation, especially if the tanks are outside and above ground or close to an extreme heat source if stored inside a structure. The more constant and cooler the tank temperatures, the less likely temperature-related fuel degradation will occur. Tank ullage (air space) should be kept to a minimum. Excess air space allows for warm, humid air to enter the tank and condense moisture during the cool evening. Also, prolonged exposure to ambient air, which is 20 percent oxygen, can facilitate oxidative degradation of the fuel. Fuel storage tanks should be kept as dry as possible and have provisions for water drainage on a regular basis. The presence of water can lead to microbiological contamination and growth, which in turn can lead to general or pitting corrosion of steel tanks and components, possibly resulting in filter plugging, operational issues, or a hydrocarbon release to the environment. Regularly scheduled surveillance of the fuel allows the operator(s) to evaluate the condition of the fuel and make important decisions regarding the quality of the fuel dedicated to reliable operation of the prime mover. Fuel maintenance and testing should begin the day of installation and first fill in order to establish a benchmark guideline for future comparison. Laboratory testing services should always be sought from a qualified or certified petroleum laboratory.

A.7.9.3.1 Fuel lines containing copper, copper-containing alloys, and zinc (including galvanized piping or containers) should be avoided. Copper can promote fuel degradation and can produce mercaptide gels. Zinc coatings can react with water or organic acids in the fuel to form gels that rapidly plug filters.

A.7.9.6 See NFPA 37, *Standard for the Installation and Use of Stationary Combustion Engines and Gas Turbines*; NFPA 54, *National Fuel Gas Code*; and NFPA 58, *Liquefied Petroleum Gas Code*.

A.7.9.7 Valving for natural gas–fueled prime movers should be configured so that the gas supply to the prime mover cannot be inadvertently or intentionally shut off by anyone other than qualified personnel such as the gas supplier. If valves are placed in an isolated area, a secure area or locking the valve(s) open is recommended.

A.7.10.3 Consideration should also be given to utilizing dampening supports where it is necessary to reduce exhaust noise vibration transmission.

A.7.11.2 If a fire suppression system is used in EPS rooms or separate buildings housing EPS equipment, consideration should be given to preaction-type suppression systems.

A.7.11.5 Consideration should be given to the location of the EPS equipment, both as it relates to the building structure and to the effects of an earthquake.

All emergency power equipment support or subsupport systems should be designed and constructed so that they can withstand static or anticipated seismic forces, or both, in any direction, with the minimum force value used being equal to the equipment weight.

Bolts, anchors, hangers, braces, and other restraining devices should be provided to limit earthquake-generated differential movements between the EPS nonstructural equipment and the building structure. However, the degree of isolation required for vibration and acoustical control of the EPS equipment and other equipment should be maintained.

Suspended items such as piping, conduit, ducts, and other auxiliary equipment related to the EPSS should be braced in two directions to resist swaying and excessive movement in earthquake risk areas.

Battery racks for EPS equipment and electrical items or related auxiliaries, or both, should be designed to resist internal damage and damage at the equipment supports resulting from earthquake-generated motion. Battery racks should be capable of withstanding seismic forces equal to the supported weight in any direction. Batteries should be restrained to their support to prevent vibration damage, and electrical interconnections should be provided with adequate slack to accommodate all relative deflections.

Transfer switch enclosures should be mounted so that their anchors and support structures can withstand static forces equal to the anticipated seismic shock in any direction.

Transfer switch components should be of the type that resists malfunction during dynamic excitation and should be designed to resist the anticipated seismic shock.

Where possible, EPS equipment and associated cooling systems and controls should be mounted on a single frame. The frame, in turn, should be rigidly attached to its foundation so that its anchorage can withstand static forces equal to the equipment weight in any direction. Where engine generator sets and associated cooling systems' controls cannot be mounted as an integral unit, each should be secured to meet the floating requirements previously described. Equipment not using the preferred rigid mounting should have vibration isolators with restraints capable of withstanding static forces equal to twice the weight of the supported equipment in any direction. In addition, interconnecting power, fuel, and cooling lines should be provided with adequate flexibility to allow maximum anticipated excursions without damage.

Appendages to the EPS equipment, such as day tanks, should be mounted to withstand static forces equal to the anticipated seismic shock in any direction.

A.7.11.6 Seismic shock should be simulated at the factory or in a testing laboratory on a prototype unit. Simulation should consist of a test(s) approximating actual time-history records of known seismic shocks applied to the equipment under test. Subassemblies of the total equipment could be tested separately where it is neither practical nor feasible to test the complete unit.

A.7.13.4.1.1 Cold start is typical standby condition under normal ambient conditions with coolant heaters functioning normally.

A.7.13.4.1.2 Cold start is typical standby condition under normal ambient conditions with coolant heaters functioning normally.

A.7.13.4.1.4(6) Verification of the engine start function can be accomplished by actual starting of the engine or by testing of the ATS start circuit.

A.7.13.4.3 Connection of the load bank (or a portable generator) is facilitated by providing permanently installed equipment or connection points such as spare circuit breakers or switches.

The generator set manufacturer should be consulted where the nameplate data do not indicate rating type. There is a difference between prime and standby ratings. For example, there are usually two kW nameplate ratings found on most engine-driven generators: "standby" and "prime." There can be a significant difference between the resulting kW figures when calculating 30 percent of nameplate — for example, a 100 kW standby generator is normally considered an 80 kW set for prime power: 100 kW × 30% = 30 kW, but 80 kW × 30% = 24 kW. A permanent record of the rating should be maintained and readily available.

A.7.13.4.3.1 The generator set manufacturer should be consulted where the nameplate data do not indicate rating type. There is a difference between prime and standby ratings. For example, there are usually two kW nameplate ratings found on most engine-driven generators: "standby" and "prime." There can be a significant difference between the resulting kW figures when calculating 30 percent of nameplate — for example, a 100 kW standby generator is normally considered an 80 kW set for prime power: 100 kW × 30% = 30 kW, but 80 kW × 30% = 24 kW. A permanent record of the rating should be maintained and readily available.

A.8.1 The continuing reliability and integrity of the EPSS are dependent on an established program of routine maintenance and operational testing. For more detailed information on electrical equipment maintenance, refer to NFPA 70B, *Recommended Practice for Electrical Equipment Maintenance*.

A.8.2 Where adequately secured from public access, it is desirable to locate an instruction manual, special tools and testing devices, and spare parts in the room in which the EPS is located. The articles should be mounted at a convenient location on a wall and should be enclosed in a metal or other suitable cabinet. The cabinet should accommodate the instruction manual on the inside of the door.

A.8.3.1 The suggested maintenance procedure and frequency should follow those recommended by the manufacturer. In the absence of such recommendations, Figure A.8.3.1(a) and Figure A.8.3.1(b) indicate alternate suggested procedures.

A.8.3.4 Where sealed devices are used, replacement of the complete device might be necessary. Maintenance should be performed according to manufacturer's recommendations. In the absence of such recommendations, the list given in 8.3.4 suggests minimal procedures.

Transfer switches should be subjected to an annual maintenance program including (one) major maintenance and (three) quarterly inspections. Programs should include all of the following operations. Note: Due to the critical nature of these devices, permission should be gained to perform these tasks since some of the following recommendations could cause disruption of power to the load. The following tasks should be carefully reviewed with facility management personnel to ensure agreement and plan for contingencies.

Major Maintenance

(1) Check connections.
   (a) A thermographic or temperature scan should be done prior to this visit, while the ATS is under normal (peak) load. This thermographic scan should be repeated during the EPSS load test. Results should be available to the maintenance provider so that suspect conditions can be addressed during this activity.

EPSS Maintenance Schedule

Component (as applicable)	Procedure X — Action R — Replace, if needed					Frequency W — Weekly, M — Monthly, Q — Quarterly S — Semiannually, A — Annually, Nos. indicate hours

FIGURE A.8.3.1(a) ***Continued***

(b) With power connected to the normal source, measure and record millivolt drop levels across each pole. Note: Any reading that is greater than 25 percent of the average of all poles should be carefully inspected when the ATS is de-energized.

(c) With power connected to the emergency source, measure and record millivolt drop levels across each pole. Note: Any reading that is greater than 25 percent of the average of all poles should be carefully inspected when the ATS is de-energized.

(d) If the ATS is equipped with a bypass isolation feature, operate the bypass to the connected source (emergency or normal) and repeat the steps in (a), (b), and (c). Levels should drop to approximately 50 percent of initial levels and be uniform relative to initial readings. This step verifies that the bypass feature is properly connected and that the connected load will not be affected when the automatic portion is isolated for maintenance.

(e) With power secured and both the emergency and normal sources properly locked out and tagged out, measure the micro-ohm resistance levels across the following connection points:

i. Emergency source cabling lug to bus
ii. Normal source cabling lug to bus
iii. Load cabling lug to bus
iv. Neutral cabling lug to bus
v. Load connected to normal across each pole
vi. Load connected to emergency across each pole

Note: If the ATS is equipped with an isolation bypass and the bypass remains energized, perform these tests on the isolated transfer switch unit only. DO NOT APPLY DIGITAL LOW RESISTANCE OHMMETER (DLRO) TO ENERGIZED CIRCUITS. Any value greater than 20 percent of the average value of all similar type connections requires further investigation.

(2) Inspect or test for evidence of overheating or excessive contact corrosion.

(a) With power from both sources secured and properly locked out and tagged out, remove all protective pole covers and arc chutes.

(b) Carefully inspect main contacts and other current-carrying parts for signs of corrosion or overheating. Note: Observation should correlate with previous results (i.e., thermographic or temperature evidence of higher than normal temperatures or heat migration, abnormal millivolt drop readings as previously noted, or abnormal micro-ohm (DLRO) readings as previously noted).

(c) Carefully inspect insulating materials or standoff insulators for signs of contamination (dirt, grime, oil, etc.). The combination of contaminants and possible introduction of high humidity or moisture could lead to insulation breakdown and subsequent destructive faults. Clean contaminated surfaces with a solvent approved for this purpose.

(d) Inspect control connection, plugs, and harnesses for signs of corrosion, heat, contamination, and so forth.

(e) Using a vacuum, remove all dust and debris from the ATS cabinet, transfer switch mechanism, bus, and so forth. Note: Never use compressed air to blow out dust. Doing so can blow dust and debris into controls and the transfer switch mechanism.

(f) Inspect cabinets for proper sealing. Open conduit knockouts or other penetrations should be properly sealed to prevent the introduction of dust, moisture, or other alien matter. Enclosures installed outside should be inspected for proper seal and appropriate gasketing. Ensure that enclosure door securing devices are intact and properly secured.

(g) Replace and secure all protective pole covers and chutes. Remove lockout devices and resupply normal power. If the ATS is of the bypass isolation type, reconnect the transfer switch mechanism. Observe proper manufacturer's procedures.

(3) Verify control and feature setpoints and operation.

(a) Measure and record the following data and setpoints:

i. Normal source voltage phase to phase, phase to ground, and phase to neutral
ii. Engine start time (from crank start to source available light or relay pickup)
iii. Emergency source voltage phase to phase, phase to ground, and phase to neutral
iv. Load current each phase
v. Momentary override normal deviation where provided
vi. Transfer time delay where provided
vii. Return to normal source time delay where provided
viii. Engine cooldown where provided

(b) If the connection is to a multiple-source EPS, verify the load priority of the ATS being tested and confirm this is correct given the criticality of the connected load.
(c) Verify proper operation of all indicator lights and meters and controls.
(d) Return ATS to normal service.

Quarterly Inspections

(1) Visually inspect the transfer switch control mechanism, control panel, harnesses, and cable connections for signs of moisture, corrosion, or heating.
(2) Measure and record the following data and setpoints:

(a) Normal source voltage phase to phase, phase to ground, and phase to neutral
(b) Engine start time (from crank start to source available light or relay pickup)
(c) Emergency source voltage phase to phase, phase to ground, and phase to neutral
(d) Load current each phase
(e) Momentary override normal deviation where provided
(f) Transfer time delay where provided
(g) Return to normal source time delay where provided
(h) Engine cooldown where provided

(3) If the connection is to a multiple-source EPS, verify the load priority of the ATS being tested and confirm this is correct given the criticality of the connected load.
(4) Verify proper operation of all indicator lights and meters and controls.
(5) Inspect cabinets for proper sealing. Open conduit knockouts or other penetrations should be properly sealed to prevent the introduction of dust, moisture, or other alien matter. Enclosures installed outside should be inspected for proper seal and appropriate gasketing. Ensure that enclosure door securing devices are intact and properly secured.
(6) Perform a load test using the test switch if permitted. Note: This will cause the emergency power source to start and the ATS to transfer. Be sure to gain permission from the facility management prior to performing this test.

A.8.3.5 Paralleling switchgear offers many advantages when testing and exercising. The system exercise period would be initiated by the automatic transfer switch (ATS) controls, and once operating, the system could be staged to establish appropriate loading of each EPS.

In addition, load-add, load-shed, load demand control, load optimization, and other operating and control features should be tested at appropriate intervals. Logic controls that contain load block information should be adjusted as necessary, and load priorities should be reviewed as ATS loads change.

A.8.3.6 A battery load test should be performed quarterly.

A.8.3.7 Limited fuel quality testing performed annually using appropriate ASTM standard test methods is recommended as a means to determine that existing fuel inventories are suitable for continued long-term storage. Special attention should be paid to sampling the bottom of the storage tank to verify that the stored fuel is as clean and dry as practicable and that water, sediment, or microbial growth on the tank bottom is minimized. ASTM D 975, *Standard Specification for Diesel Fuel Oils,* contains test methods for existing diesel fuel.

A.8.4.1 Weekly inspection does not require running of the EPS. Running unloaded generators as part of this weekly inspection can result in long-term problems such as wet stacking. See Figure A.8.4.1(a) and Figure A.8.4.1(b).

A.8.4.2 Light loading creates a condition termed *wet stacking,* indicating the presence of unburned fuel or carbon, or both, in the exhaust system. Its presence is readily indicated by the presence of continuous black smoke during engine-run operation. The testing requirements of 8.4.2 are intended to reduce the possibility of wet stacking. If equivalent loads are used for exercising, it is suggested that all essential loads be energized first, with the equivalent load used only to supplement the test. If the normal power were to fail during the exercise period, it would negate the urgency to automatically remove the equivalent load as described in 8.4.2.2.

The generator set manufacturer should be consulted where the nameplate data do not indicate rating type. There is a difference between prime and standby ratings. For example, there are usually two kW nameplate ratings found on most engine-driven generators: "standby" and "prime." There can be a significant difference between the resulting kW figures when calculating 30 percent of nameplate — for example, a 100 kW standby generator is normally considered an 80 kW set for prime power: 100 kW × 30% = 30 kW, but 80 kW × 30% = 24 kW. A permanent record of the rating should be maintained and readily available.

A.8.4.2.3 The generator set manufacturer should be consulted where the nameplate data do not indicate rating type. There is a difference between prime and standby ratings. For example, there are usually two kW nameplate ratings found on most engine-driven generators: "standby" and "prime." There can be a significant difference between the resulting kW figures when calculating 30 percent of nameplate — for example, a 100 kW standby generator is normally considered an 80 kW set for prime power: 100 kW × 30% = 30 kW, but 80 kW × 30% = 24 kW. A permanent record of the rating should be maintained and readily available.

FIGURE A.8.4.1(a) Sample Operation and Testing Log for Rotating Equipment.

Suggested Operation and Testing Procedures

Item*	Procedure
1.	Perform maintenance per Maintenance Schedule
2.	Record running time meter (RTM) reading at start and end of test.
3.	Simulate normal power failure from a "cold start" by use of the test switch in automatic transfer switch or by opening normal power supply to EPSS.
4.	Observe and record time delay (T/D) on start.
5.	Record cranking time (terminates when engine starts).
6.	Transfer load to EPS.
7.	Record ac voltage, frequency, amperage, kW.
8.	Record initial oil pressure and battery-charging rate.
9.	Record oil pressure, battery-charging rate, and water or air temperature after 15 minutes running time.
10.	Return test switch to normal or reestablish normal power supply at such time to cause a minimum running time of 30 minutes under load.
11.	Record prime mover and ac instruments just prior to transfer.
12.	Record time delay on retransfer.
13.	Record time delay on shutdown for units so equipped.
14.	Place unit in automatic operation mode.

*See Operation and Testing Log.

FIGURE A.8.4.1(b) Operation and Testing Procedures Suggested for Rotating Equipment.

A.8.4.3.1 The intent is to verify the starting function from each ATS to the EPS by rotating the ATS that initiates the cold engine start of the monthly test. For example, if the facility has 37 ATSs, it can take more than 3 years to verify the starting function of the ATSs. Consideration should be given to ATS criticality. Once the testing cycle is completed, in subsequent years the testing order can be modified to reflect changes to the EPSS.

A.8.4.6.1 This requirement is to simulate a power outage without turning off normal power. This requirement allows selected ATSs to be transferred back to normal before the entire 30-minute test is complete when required for operational or safety considerations.

Selected ATSs can be electrically operated at a different time than the monthly operational test when required for operational or safety considerations, provided the monthly requirement of 8.4.6 is met.

A.8.4.7 Circuit breakers should be tested under simulated overload conditions every 2 years.

A.8.4.9 The intent of this requirement is to provide reasonable assurance that the EPSS with all of its auxiliary subsystems is capable of running for the duration of its assigned class with its running load. A full facility power outage is not intended for this test but is recommended where a total facility power outage has not occurred within the last 36 months. Supplemental load banks are not required. After the test, the fuel supply should be replenished if necessary.

A.8.4.9.5.1 The generator set manufacturer should be consulted where the nameplate data do not indicate rating type. There is a difference between prime and standby ratings. For example, there are usually two kW nameplate ratings found on most engine-driven generators: "standby" and "prime." There can be a significant difference between the resulting kW figures when calculating 30 percent of nameplate — for example, a 100 kW standby generator is normally considered an 80 kW set for prime power: 100 kW × 30% = 30 kW, but 80 kW × 30% = 24 kW. A permanent record of the rating should be maintained and readily available.

A.8.4.9.7 The generator set manufacturer should be consulted where the nameplate data do not indicate rating type. There is a difference between prime and standby ratings. For example, there are usually two kW nameplate ratings found on most engine-driven generators: "standby" and "prime." There can be a significant difference between the resulting kW figures when calculating 30 percent of nameplate — for example, a 100 kW standby generator is normally considered an 80 kW set for prime power: 100 kW × 30% = 30 kW, but 80 kW × 30% = 24 kW. A permanent record of the rating should be maintained and readily available.

Annex B Diagrams of Typical Systems

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

NFPA® 111

Standard on

Stored Electrical Energy Emergency and Standby Power Systems

2016 Edition

This edition of NFPA 111, *Standard on Stored Electrical Energy Emergency and Standby Power Systems,* was prepared by the Technical Committee on Emergency Power Supplies and released by the Correlating Committee on National Electrical Code®. It was issued by the Standards Council on May 26, 2015, with an effective date of June 15, 2015, and supersedes all previous editions.

A Tentative Interim Amendment (TIA) to Table 4.2.2 was issued on August 18, 2015. For further information on tentative iterim amendments, see Section 5 of the Regulations Governing the Development of NFPA Standards, available at: http://www.nfpa.org/regs.

This edition of NFPA 111 was approved as an American National Standard on June 15, 2015.

Origin and Development of NFPA 111

The Technical Committee on Emergency Power Supplies was organized in 1976 by NFPA in recognition of the demand for guidelines on the assembly, installation, and performance of electrical power systems to supply critical and essential needs during outages of the normal power source. During the development of a base standard (NFPA 110, *Standard for Emergency and Standby Power Systems*), it was determined that several power sources were available for emergency and standby power systems. The committee determined that sufficient differences existed between these sources to justify separate documents providing clearly defined specifics. Each document would follow the basic format of NFPA 110 to provide a consistent basis for comparison and usage and would remain under the jurisdiction of the Technical Committee on Emergency Power Supplies.

Because of the unique knowledge necessary to provide an authoritative document, the technical committee authorized a subcommittee in 1982 to prepare a draft document on systems using stored energy sources. In 1986, a document tentatively titled NFPA 110A, *Stored Energy Emergency and Standby Power Systems,* was submitted for adoption at the 1989 NFPA Annual Meeting.

Formally designated as NFPA 111, this document addressed the performance of stored energy systems with appropriate equipment detail. The requirements of the standard were considered necessary to obtain the minimum level of reliability and performance and to achieve an on-site stored energy auxiliary electrical power source suitable to the needs of the applicable requirements. If followed, its use would result in a system suitable for various situations as required by other codes and standards.

The second edition in 1993 contained only minor changes.

For the 1996 edition, a section was added to cover the acceptability of systems, methods, and devices other than those listed in the document.

The 2001 edition contained two changes: informational text was moved to the appendix and the operational testing requirements were expanded.

The 2005 edition underwent a complete rewrite in accordance with the *Manual of Style* for NFPA Technical Committee Documents. Along with the rewrite, some of the definitions were revised and located in Chapter 3. Other data in the document were transferred to the table format for better usability.

NFPA and National Fire Protection Association are registered trademarks of the National Fire Protection Association, Quincy, Massachusetts 02169.

The 2010 edition revised the document scope to clarify that an uninterruptible power supply (UPS) supplied through an emergency power supply (EPS) is not a stored emergency power supply system (SEPSS). The definitions of automatic transfer switch and nonautomatic transfer switch were revised to correlate with NFPA 110. New definitions covered battery cell types, bridging systems, and electrochemical energy storage devices. Energy sources, convertors, inverters, and accessories were covered by Chapter 5 revisions that clarified existing requirements, recognized new battery types, and provided requirements covering stored energy sources other than batteries. Revisions to area ventilation requirements acknowledged that there might be flammable gases other than hydrogen associated with energy sources that are not batteries. Annex diagrams were added to illustrate flywheel and rotating EPS systems, different UPS systems, and basic switching points of an SEPSS.

A rectifier plant, which is often used in the telecommunications industry, was added in 2013 as a potential stored emergency power supply system (SEPSS). These rectifier plants were also included as a suitable bridging system. The location of SEPSS equipment serving Level 1 EPSS loads was revised to correlate with the requirements of NFPA 110.

Throughout the 2016 edition, references to a stored emergency power supply system have been revised to a stored-energy emergency power supply system to more appropriately describe the type of system. Requirements for baseline measurements have been revised to provide more accurate data. The load test has been revised to correlate with the IEEE 450 rate-adjusted and time-adjusted capacity tests.

This list represents the membership at the time the Committee was balloted on the final text of this edition. Since that time, changes in the membership may have occurred. A key to classifications is found at the back of the document.

NOTE: Membership on a committee shall not in and of itself constitute an endorsement of the Association or any document developed by the committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on performance criteria for the selection and assembly of the components for emergency and standby power systems in buildings and facilities, including categories of power supplies, transfer equipment, controls, supervisory equipment, and all related electrical and mechanical auxiliary or accessory equipment needed to supply emergency or standby power to the utilization equipment. The Committee also shall be responsible for criteria on the maintenance and testing of the system. This Committee does not cover requirements for the application of emergency power systems, self-contained emergency lighting units, and electrical wiring, except that wiring that is an integral part of the system up to the load side of the transfer switch(es). This Committee shall report to Technical Correlating Committee of the National Electrical Code.

NFPA 111

Standard on

Stored Electrical Energy Emergency and Standby Power Systems

2016 Edition

IMPORTANT NOTE: This NFPA document is made available for use subject to important notices and legal disclaimers. These notices and disclaimers appear in all publications containing this document and may be found under the heading "Important Notices and Disclaimers Concerning NFPA Standards." They can also be obtained on request from NFPA or viewed at www.nfpa.org/disclaimers.

UPDATES, ALERTS, AND FUTURE EDITIONS: New editions of NFPA codes, standards, recommended practices, and guides (i.e., NFPA Standards) are released on scheduled revision cycles. This edition may be superseded by a later one, or it may be amended outside of its scheduled revision cycle through the issuance of Tentative Interim Amendments (TIAs). An official NFPA Standard at any point in time consists of the current edition of the document, together with any TIAs and Errata in effect. To verify that this document is the current edition or to determine if it has been amended by any TIAs or Errata, please consult the National Fire Codes® Subscription Service or visit the Document Information (DocInfo) pages on the NFPA website at www.nfpa.org/docinfo. In addition to TIAs and Errata, the DocInfo pages also include the option to sign up for Alerts for each document and to be involved in the development of the next edition.

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates that explanatory material on the paragraph can be found in Annex A.

A reference in brackets [ ] following a section or paragraph indicates material that has been extracted from another NFPA document. As an aid to the user, the complete title and edition of the source documents for extracts in mandatory sections of the document are given in Chapter 2 and those for extracts in informational sections are given in Annex C. Extracted text may be edited for consistency and style and may include the revision of internal paragraph references and other references as appropriate. Requests for interpretations or revisions of extracted text shall be sent to the technical committee responsible for the source document.

Information on referenced publications can be found in Chapter 2 and Annex C.

Chapter 1 Administration

1.1 Scope.

1.1.1* This standard shall cover performance requirements for stored electrical energy systems providing an alternate source of electrical power in buildings and facilities in the event that the normal electrical power source fails.

1.1.2 Systems covered in this standard shall include power sources, transfer equipment, controls, supervisory equipment, and accessory equipment, including integral accessory equipment, needed to supply electrical power to the selected circuits.

1.1.3 This standard shall cover installation, maintenance, operation, and testing requirements as they pertain to the performance of the stored-energy emergency power supply system (SEPSS).

1.1.4 Exclusions.

1.1.4.1* This standard shall not cover the following:

(1) Application of the SEPSS
(2) Distribution wiring
(3) Systems having total outputs less than 500 VA or less than 24 V or systems less than Class 0.033
(4) Unit equipment
(5) Nuclear sources, solar systems, and wind stored-energy systems
(6) Uninterruptible power systems (UPS) supplied by an emergency power supply system (EPSS) or a UPS supplied by a SEPSS
(7) Optional standby systems

1.1.4.2 The following shall not be within the scope of this standard:

(1) Specific buildings or facilities, or both, requiring an SEPSS
(2) Specific loads to be served by the SEPSS
(3) Type, class, or level to be assigned to any specific load *(See Section 4.1.)*

1.2 Purpose.

1.2.1 This standard shall provide performance requirements for SEPSS and also shall be used in conjunction with other standards.

1.2.2 It shall be the role of other NFPA standards to specify which occupancies require an SEPSS and the applicable level, type, and class.

1.2.3 This standard shall not specify where an SEPSS is required. *(See 1.1.4.2.)*

1.2.4 This standard shall provide guidance for inspectors, designers, installers, manufacturers, and users of an SEPSS and shall serve as a basis for communication between the parties involved.

1.2.5 This standard shall not be considered a design manual.

1.2.6 Compliance with this standard shall not absolve the parties involved of their respective responsibilities for the design, installation, maintenance, performance, or compliance with other applicable standards and codes.

1.2.7 The installation of a stored-energy system(s) conforming to this standard shall ensure that alternate power is available to minimize life safety hazards resulting from power loss to certain continuous chemical or industrial processes, computer controlled systems, emergency lighting, and the like.

1.3 Application.

1.3.1 This document shall apply to new installations of SEPSS.

1.3.2 Existing systems shall not be required to be modified to conform except where the authority having jurisdiction determines that nonconformity presents a distinct hazard to life.

1.4 Equivalency. Nothing in this standard shall be intended to prevent the use of systems, methods, or devices of equivalent or superior quality, strength, fire resistance, effectiveness, durability, and safety to those prescribed by this document, provided the requirements of 1.4.1 and 1.4.2 are met.

1.4.1 Technical documentation shall be submitted to the authority having jurisdiction to demonstrate equivalency.

1.4.2 The system, method, or device shall be approved for the intended purpose by the authority having jurisdiction.

1.5 Function.

1.5.1 SEPSS shall provide a source of electrical power of required capacity, reliability, and quality to loads for a given length of time within a specified time after loss, failure, or disruption of the normal power supply.

1.5.2 An SEPSS shall include a means to recharge the stored-energy system.

Chapter 2 Referenced Publications

2.1 General. The documents or portions thereof listed in this chapter are referenced within this standard and shall be considered part of the requirements of this document.

2.2 NFPA Publications. National Fire Protection Association, 1 Batterymarch Park, Quincy, MA 02169-7471.

NFPA 1, *Fire Code,* 2015 edition.

NFPA 70®, National Electrical Code®, 2014 edition.

NFPA 72®, National Fire Alarm and Signaling Code, 2016 edition.

2.3 Other Publications.

2.3.1 ASCE Publications. American Society of Civil Engineers, 1801 Alexander Bell Drive, Reston, VA 20191-4400.

ASCE/SEI 7, *Minimum Design Loads for Buildings and Other Structures,* 2010.

2.3.2 Other Publications.

Merriam-Webster's Collegiate Dictionary, 11th edition, Merriam-Webster, Inc., Springfield, MA, 2003.

2.4 References for Extracts in Mandatory Sections.

NFPA 1, *Fire Code,* 2015 edition.

NFPA 110, *Standard for Emergency and Standby Power Systems,* 2016 edition.

Chapter 3 Definitions

3.1 General. The definitions contained in this chapter shall apply to the terms used in this standard. Where terms are not defined in this chapter or within another chapter, they shall be defined using their ordinarily accepted meanings within the context in which they are used. *Merriam-Webster's Collegiate Dictionary,* 11th edition, shall be the source for the ordinarily accepted meaning.

3.2 NFPA Official Definitions.

3.2.1* Approved. Acceptable to the authority having jurisdiction.

3.2.2* Authority Having Jurisdiction (AHJ). An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

3.2.3 Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

3.2.4* Listed. Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

3.2.5 Shall. Indicates a mandatory requirement.

3.2.6 Should. Indicates a recommendation or that which is advised but not required.

3.2.7 Standard. An NFPA Standard, the main text of which contains only mandatory provisions using the word "shall" to indicate requirements and that is in a form generally suitable for mandatory reference by another standard or code or for adoption into law. Nonmandatory provisions are not to be considered a part of the requirements of a standard and shall be located in an appendix, annex, footnote, informational note, or other means as permitted in the NFPA Manuals of Style. When used in a generic sense, such as in the phrase "standards development process" or "standards development activities," the term "standards" includes all NFPA Standards, including Codes, Standards, Recommended Practices, and Guides.

3.3 General Definitions.

3.3.1 Battery. Two or more cells connected together electrically in series or parallel, or both, to provide the required operating voltage and current levels.

3.3.1.1* ***Lead-Acid (LA) Cell.*** A secondary cell in which the active material of the positive electrode is lead dioxide, the active material of the negative electrode is lead, and the electrolyte is dilute sulfuric acid.

3.3.1.1.1* ***Valve-Regulated (VRLA).*** A lead-acid battery consisting of sealed cells furnished with a valve that opens to vent the battery whenever the internal pressure of the battery exceeds the ambient pressure by a set amount. [**1,** 2015]

3.3.1.1.2* ***Vented (Flooded).*** A lead-acid battery consisting of cells that have electrodes immersed in liquid electrolyte. [**1,** 2015]

3.3.1.2 ***Nickel-Cadmium (NiCd) Cell.*** A secondary cell in which the active material of the positive electrode is nickel oxyhydroxide, the active material of the negative electrode is cadmium, and the electrolyte is dilute potassium hydroxide.

3.3.1.3 ***Nickel-Metal Hydride (NiMH) Cell.*** A secondary cell in which the active material of the negative electrode is a hydrogen-absorbing alloy and the positive electrode is nickel.

3.3.2* Bridging System. A type of energy conversion equipment (ECE) intended to temporarily support the critical load with stored energy until an alternate energy source can assume the load.

3.3.3* Electrochemical Energy Storage Device. A device based on the interrelated transformations of chemical and electric energy, usually consisting of an anode, a cathode, and an electrolyte plus such connections (electrical and mechanical) as needed to allow the cell to deliver or receive electric energy.

3.3.4 Emergency Power Supply. See 3.3.8.1.

3.3.5 Emergency Power Supply System (EPSS). A complete functioning EPS system coupled to a system of conductors, disconnecting means and overcurrent protective devices, transfer switches, and all control, supervisory, and support devices up to and including the load terminals of the transfer equipment needed for the system to operate as a safe and reliable source of electric power. [**110,** 2016]

3.3.5.1 ***Stored-Energy Emergency Power Supply System (SEPSS).*** A system consisting of a UPS, a rectifier plant, or a motor generator powered by a stored electrical energy source; a transfer switch designed to monitor preferred and alternate load power source and provide desired switching of the load; and all necessary control equipment to make the system functional.

3.3.6 Energy Conversion Equipment (ECE). A system of either a UPS, a battery bank and battery charger (central battery system), or a rotating motor generator (with or without inertia flywheel), often supplied by a central battery system power source.

3.3.7 Internal Ohmic Measurement. A measurement of the electronic and ionic conduction path within a cell or unit, using techniques commonly known as impedance, conductance, or resistance tests.

3.3.8 Power Supply.

3.3.8.1* ***Emergency Power Supply (EPS).*** The source of electric power of the required capacity and quality for an emergency power supply system (EPSS). [**110,** 2016]

3.3.8.2* ***Uninterruptible Power Supply (UPS).*** A device or system that provides quality and continuity of ac power through the use of a stored-energy device as the backup power source during any period when the normal power supply is incapable of performing acceptably.

3.3.9 Transfer Switch.

3.3.9.1 ***Automatic Transfer Switch (ATS).*** Self-acting equipment for transferring the connected load from one power source to another power source. [**110,** 2016]

3.3.9.2 ***Nonautomatic Transfer Switch.*** A device, operated manually by a physical action or electrically by either a local or remote control, for transferring a common load between a normal and alternate supply. [**110,** 2016]

Chapter 4 Classification of Stored-Energy Emergency Power Supply Systems (SEPSS)

4.1* General. Stored-energy emergency power supply systems (SEPSS) shall be classified as detailed in Sections 4.2 through 4.5.

4.2 Type.

4.2.1 The type shall determine the maximum time, in seconds, that the SEPSS will permit the load terminals of the transfer switch to be without acceptable electrical power.

4.2.2* The interruption times of the SEPSS types covered by this standard shall be as provided in Table 4.2.2.

Table 4.2.2 was revised by a tentative interim amendment (TIA). See page 1.

Table 4.2.2 Types of SEPSS

Type	Interruption Time
Type O	No interruptions — UPS carrying load, 0.0 sec
Type U	UPS system with utility as preferred source
Type A	0.25 cycle: 0.0042 sec
Type B	1.0 cycle: 0.0167 sec
Type 10	10 sec
Type M	Manual stationary or nonautomatic — no time limit

4.3* Class. The class shall determine the minimum time, in hours, for which the SEPSS is designed to operate at its rated load without being refueled or recharged as shown in Table 4.3.

Table 4.3 Classes of SEPSS

Class	Reserve Time
Class 0.033	0.033 hr (2 min)
Class 0.083	0.083 hr (5 min)
Class 0.25	0.25 hr (15 min)
Class 1.5	1.5 hr (90 min)
Class X	Other time, in hours, as required by the application, code, or user

4.4 Category. This standard shall regulate stored-energy devices into the following two categories:

(1) Category A includes stored-energy devices receiving their energy solely from the normal supply under conditions of normal operation.
(2) Category B includes all devices not included in Category A and not specifically excluded elsewhere in this standard.

4.5* Level. The level of equipment installation, performance, and maintenance shall be as specified in 4.5.1 through 4.5.5.

4.5.1* Level 1 systems shall be installed where failure of the equipment to perform could result in loss of human life or serious injuries.

4.5.2* Level 2 systems shall be installed where failure of the EPSS to perform is less critical to human life and safety.

4.5.3 All equipment shall be permanently installed.

4.5.4* Level 1 and Level 2 SEPSS shall supply alternate power of a quality that ensures reliable operation of the load, within the time determined by the type and for a duration determined by the class.

4.5.5* Other equipment and applications, including optional standby systems, not defined in Levels 1 and 2 are beyond the scope of this document.

Chapter 5 Emergency Power Supply: Energy Sources, Convertors, Inverters, and Accessories

5.1 Energy Sources. The energy sources listed in this section shall be permitted for use for the emergency power supply (EPS).

5.1.1 Battery Systems.

5.1.1.1* Battery Types. Electrical storage batteries having a construction and chemical composition suitable for standby, float service operation shall consist of one of the following:

(1) Lead-acid batteries (LA)
(2) Nickel-cadmium batteries (NiCd)
(3) Nickel-metal hydride batteries (NiMH)
(4) Lithium ion (LI) batteries

5.1.1.2 Battery System Electrolyte. The following batteries shall be permitted with either free-flowing or immobilized electrolyte:

(1) LA
(2) NiCd
(3) NiMH

5.1.1.3 Battery Installation. Battery installations shall comply with the following:

(1) Vented batteries (LA, NiCd, NiMH) shall be installed in a room(s) dedicated to the batteries and associated equipment with approved ventilation.
(2) Vented batteries shall be mounted on open racks.
(3) Sealed and valve-regulated batteries (VRLA, NiMH, LI) shall be permitted in dedicated battery rooms. Batteries shall be mounted in either of the following ways:
    (a) On open racks
    (b) In listed battery cabinets
(4) Distributed sealed and valve-regulated batteries (VRLA, NiMH, LI) shall be permitted in occupied spaces and shall be mounted in one of the following ways:
    (a) In listed battery cabinets with restricted access (tool or key required)
    (b) In listed console or package style
    (c) In a combination of (a) and (b)

5.1.2* Mechanical Inertia Systems. Flywheel systems shall be installed in dedicated equipment rooms with restricted access or in enclosures with restricted access.

5.2 Energy Conversion Equipment (ECE) — General. ECE covered by this standard shall pertain to systems utilizing electrochemical devices, mechanical inertia devices, or both, with related control, conversion, and accessory items.

5.2.1* Bridging Systems. Bridging systems shall be capable of supporting the load for a finite period of time until the emergency or standby power source is able to assume the load.

5.2.1.1* The following electrochemical bridging systems shall be permitted:

(1) Solid state (static) UPS systems of the following types:
    (a) On-line UPS capable of assuming the load without interruption upon loss of the primary input source
    (b) Standby and off-line (UPS) capable of assuming the load within a specified time frame and without interruption of the load operation upon loss of the primary input source
(2) Ultracapacitor systems integrated into the following types of systems:
    (a) UPS systems capable of sustaining the load without interruption upon momentary loss or degradation of the primary input source with or without battery
    (b) Fuel cell systems capable of sustaining the load without interruption upon loss of input power until the fuel cell assumes the load
(3) Solid state (static) rectifier plants capable of providing continuous power to the dc load(s) without interruption or disturbance upon loss of the primary input source

5.2.2 Mechanical Inertia Systems. Flywheel systems shall sustain the load without interruption upon momentary loss or degradation of input power until power is restored or an emergency or standby power source assumes the load.

5.2.3 Level. The ECE for each level shall be of proven design and components whose performance and reliability have been documented.

5.2.4 Class. The ECE shall be identified by the manufacturer for the specified class.

5.2.5 Output. The output of an ECE shall be of the voltages, waveform, and frequency rated for the load.

5.2.6 Temperature. ECEs shall be designed to operate over the following expected environmental temperature ranges:

(1) Indoor: 10°C to 40°C (50°F to 104°F)
(2) Outdoor: −34°C to 50°C (−30°F to 122°F)

5.2.7* Humidity. The ECE shall be designed to function in an atmosphere having a relative humidity that can vary from 5 percent to 95 percent, noncondensing.

5.2.8 Capacity.

5.2.8.1 Class. The ECE shall have the capacity to supply power for the class for which it is rated.

5.2.8.2 Stored-Energy Recovery. Following a power outage for the full duration of the assigned class, the ECE shall be capable of automatically resupplying the full rated load and duration within the time appropriate for the technology as follows:

(1) Battery-based systems with a charger identified for the battery type and capable of recharging as follows:
    (a) 80 percent within 12 times the discharge period
    (b) 100 percent within 48 hours
(2) Ultracapacitor-based systems: 100 percent within 1 hour
(3) Mechanical inertia–based systems: 100 percent within 1 hour

5.3 Instrumentation.

5.3.1 Instruments. The SEPSS shall be provided with instruments or other approved display means, including remote annunciation capability, to indicate the requirements shown in Table 5.3.1, where applicable to the technology.

Table 5.3.1 Instrumentation Display Indicator

Device	Level 1	Level 2
Battery voltage	X	X
System output voltage, each leg	X	X
System output current, each leg	X	X
System output frequency (ac output systems only)	X	X

X = Required.

5.3.2 Indicators. Individual visual indicators and a common audible annunciator shall be provided for the requirements shown in Table 5.3.2.

Table 5.3.2 Visual Indicator Display Indicator

Device	Level 1	Level 2
Load on normal power	X	X
Load on emergency power	X	X
Output circuit breaker open	X	O
Output overload/overcurrent	X	X
High temperature	X	X
ECE in bypass mode	X	X
Low battery (if present)	X	X
Major alarm condition	X	X
Minor alarm condition	X	X

X = Required. O = Not Required.

5.3.3* Annunciation.

5.3.3.1 The following monitoring shall be provided at a minimum:

(1) For Level 1 SEPSS, local annunciation and facility remote annunciation, or local annunciation and network remote annunciation
(2) For Level 2 SEPSS, local annunciation

5.3.3.2 For the purposes of this section, the following shall be permitted:

(1) Local annunciation located on the equipment itself or within the same equipment room.
(2) Facility remote annunciation located on site but not within the room where the equipment is located.
(3) Network remote annunciation located off site.

Chapter 6 Transfer Switches and Protection

6.1 General.

6.1.1* Switching, as used in this chapter, shall refer to any electrical or electronic equipment that is used as follows:

(1) To transfer an electrical load from one power source to another
(2) To perform load-switching or load-shedding functions on any electrical load
(3) To bypass, isolate, and test any transfer or isolation switch in the static system
(4) To isolate any faulted component inside the static system so that it ceases to be connected to the output load terminals
(5) To bypass the energy conversion equipment (ECE)

6.1.2 Protection, as used in this chapter, shall reference electronic-sensing or inherent overload protective devices, such as fuses, automatic breakers, or both, that are used to protect the static system against damage caused by faults or overloads on either the output of the static system in its loads or conductors, or on internal faults in the static system.

6.1.3* Equipment used with batteries or other dc sources shall be identified and rated for the dc voltage and current.

6.2 Transfer Switches.

6.2.1 General. Transfer switches shall be rated for transferring the connected loads between the energy converter and the building electrical service.

6.2.1.1 Transfer switches shall be permitted to be electrical or electronic or a hybrid of both.

6.2.1.2 Any transfer switch shall be rated for transferring all connected electrical loads from one power source to another.

6.2.1.3 Transfer switch characteristics shall be sized for the connected electrical load.

6.2.1.4 Transfer switches shall provide rated isolation between the electrical load and the alternate source(s).

6.2.1.5 Transfer switches shall be permitted to be separate devices within their own enclosures or an integral part of the ECE.

6.2.1.6 The capacity and endurance rating of transfer switches shall be sized for all classes of loads to be served.

6.2.1.7 The method of operation of transfer switches shall ensure that the most likely causes of switch failure result in the loads being connected to the building service.

6.2.1.8 Means shall be provided to check the operation of the transfer switch.

6.2.2* Switch Capacity.

6.2.2.1 The capacity of the transfer switch, electronic or electromechanical, shall be rated for all classes of loads to be served.

6.2.2.2 The transfer switch, including all load current–carrying components, shall be rated to withstand the effects of available fault currents.

6.2.3 Transfer Switch Classification.

6.2.3.1 Each transfer switch shall be listed for emergency service as a completely factory-assembled and factory-tested apparatus unless under the conditions of 6.2.3.2.

6.2.3.2 Electronic or electromechanical switches that constitute an integral part of the ECE shall be permitted, provided they form part of a listed equipment.

6.2.4 Automatic Transfer Switch (ATS) Features.

6.2.4.1 General. Automatic transfer switches shall be electrically or electronically operated.

6.2.4.1.1 The transfer of the load from one source to another source shall be permitted to be automatic.

6.2.4.1.2 The retransfer shall be permitted to be automatically or manually initiated.

6.2.4.2 Source Monitoring. The preferred source shall be monitored for undervoltage and overvoltage on all its ungrounded input lines.

6.2.4.2.1 The ECE and the utility shall be monitored for unacceptable conditions.

6.2.4.2.2 If a condition that is out of tolerance is sensed, the transfer switch shall automatically switch to the alternate source(s) of power, provided that the alternate source(s) of power itself is within tolerance.

6.2.4.2.3 When the preferred source of power returns to levels of output within equipment tolerance in its sensed parameters as described in 6.2.4.2, the transfer switch shall be capable of initiating an automatic transfer to the preferred source.

6.2.4.2.4 An adjustable time delay shall be allowed to ensure that the preferred source is within its steady-state specification limits before such retransfer is performed.

6.2.4.2.5 Provision for retransfer to the preferred source also shall be available under manual command, provided the preferred source is within tolerance.

6.2.4.2.6 Retransfer shall be permitted to be sequenced if desired to pick up heavy loads without introducing further disturbances.

6.2.4.3 Interlocking.

6.2.4.3.1 Interlocking shall be provided to prevent inadvertent interconnection of the preferred and alternate power sources unless under the conditions of 6.2.4.3.2.

6.2.4.3.2 Where interconnection is inherent in the system design, the preferred and alternate sources of power shall not be connected together longer than is necessary to transfer the preferred sources of power, without disturbance to the electrical loads connected to it, provided that such interconnection can be sustained by the two connected sources of incoming power without causing internal current protection features to be initiated.

6.2.4.4* Manual Operation. Instruction and equipment shall be provided for the manual nonelectric transfer or bypass in the event the automatic transfer switch malfunctions.

6.2.4.5* Time Delay on Retransfer to Preferred Source.

6.2.4.5.1 An adjustable time delay device with automatic bypass shall be provided to delay retransfer from the alternate source to the preferred source of power.

6.2.4.5.2 The time delay shall be automatically bypassed if the ECE or EPS fails.

6.2.4.6 Test Switch.

6.2.4.6.1 A test switch shall be provided on each automatic transfer switch that simulates failure of the preferred power source.

6.2.4.6.2 The automatic transfer switch shall perform its intended function when the test switch is activated.

6.2.5 Nonautomatic Transfer Switch Features.

6.2.5.1 General. Manual control of switching devices shall be permitted to be either local or remote.

6.2.5.1.1 When initiated, a device shall switch to its alternate state and shall remain in that state.

6.2.5.1.2 Upon cessation of the initiating control action, the device shall return to its preferred state.

6.2.5.2 Interlocking. Reliable mechanical interlocking, or an approved alternate method, shall prevent the inadvertent interconnection of the preferred and alternate power sources or of any two separate sources of power.

6.2.5.3 Indication of Switch Position. Two pilot lights with identification nameplates, or other approved position indicators, shall be provided to indicate the switch position.

6.3 Load Switching (Load Shedding).

6.3.1 General. When the connected load exceeds the capacity of the ECE, system controls shall automatically do one of the following:

(1) Disconnect pre-identified noncritical loads
(2) Transfer the loads to bypass

6.3.2 Transfer Switch Rating.

6.3.2.1 Each transfer switch shall have a continuous current rating and interrupting rating for all classes of loads to be served.

6.3.2.2 The transfer switch shall be capable of withstanding the available fault current at the point of installation.

6.3.3 Operation. First priority loads shall be switched to the emergency bus (if not already on that bus) when the emergency source is made available to their switching devices.

6.3.3.1 The remaining lower priority loads shall be switched to the emergency bus thereafter, provided the emergency bus is not overloaded by such switching, until all such emergency loads of lower priority are on the emergency bus.

6.3.3.2 The total loading on the emergency bus also shall be reduced by switching off the loads in inverse priority order, in proportion to the lost power capacity of the isolated module, when both of the following conditions exist:

(1) Any static power module connected to the emergency bus is isolated from that bus due to internal failure.
(2) The remaining connected power modules cannot serve the total connected load because they are overloaded.

6.3.3.3 Disconnecting the lower priority loads (load shedding) shall cease when the load demand matches the connected capacity of the remaining modules.

6.4 Bypass Switches.

6.4.1* Isolation. Bypass switches, with or without isolation, shall be permitted for bypassing or for bypassing and isolating the transfer switch, and if installed, bypass switches shall be in accordance with 6.4.2 and 6.4.3.

6.4.2 Bypass Switch Rating. The bypass switch shall have a continuous current rating and shall withstand a current rating compatible with that of the associated transfer switch.

Exception: UPS static bypass transfer switches shall be permitted to have a current rating and interrupting rating for all classes of loads to be served sufficient to support all connected loads from either source.

6.4.3 Bypass Switch Classification. Each bypass switch shall be designed for emergency electrical service as a completely factory-assembled and factory-tested apparatus.

6.5 Protection.

6.5.1* General.

6.5.1.1 The overcurrent protective devices in the SEPSS shall be coordinated to ensure selective tripping of the circuit overcurrent protective devices when a short-circuit current occurs.

6.5.1.2 The maximum available short-circuit current from both the utility source and the emergency energy source shall be evaluated to verify compliance with this coordination.

6.5.2 Overcurrent Protective Device Rating.

6.5.2.1 The rating of integral devices (e.g., fuses or breakers) shall be coordinated with the rating of downstream protective devices, taking into account the prospective short-circuit current available from the connected upstream power sources, such that the downstream devices operate first to eliminate the least critical portion of the connected electrical load.

6.5.2.2 In those cases where electronic protection is incorporated via feedback to limit the current output of the ECE, the internal transfer switch(es) shall operate to switch the connected electrical load to the alternate source.

6.5.3 Accessibility. Overcurrent devices in EPSS circuits shall be accessible to authorized persons only.

Chapter 7 Installation and Environmental Considerations

7.1 General.

7.1.1 This chapter shall provide the minimum requirements and considerations for an SEPSS relative to the installation and environmental conditions that could adversely affect its performance.

7.1.2 When the location of the SEPSS is evaluated, consideration shall be given to the geographic location, building type, classification of occupancy, and hazardous nature of the area.

7.1.3 The SEPSS equipment shall be installed in a manner and location recommended by the manufacturer and acceptable to the authority having jurisdiction.

7.1.4 Where normal power is available, the EPS shall serve Level 1 and Level 2 system loads and shall be permitted to serve additional loads, provided that, on failure of the normal power, the additional loads are automatically dropped to ensure that the EPS has sufficient capacity to serve the Level 1 and Level 2 loads.

7.2 Location.

7.2.1* The SEPSS shall be located in a room(s) in accordance with the manufacturer's environmental specifications.

7.2.1.1 The location of SEPSS equipment serving Level 1 EPSS loads shall not be installed in the same room with the normal supply equipment, where the supply equipment is rated over 150 volts to ground and equal to or greater than 1000 amperes.

7.2.2 The rooms or buildings housing the SEPSS shall be located to minimize the possibility of damage from flooding, including flooding resulting from fire fighting, sewer water backup, and similar disasters or occurrences.

7.2.3 SEPSS Equipment.

7.2.3.1 The SEPSS equipment shall be installed in a location that allows for equipment accessibility and working space clearance for the inspection, repair, maintenance, cleaning, or replacement of the unit per Table 110.26(A)(1) of *NFPA 70 (NEC)*.

7.2.3.2 A separate unit emergency lighting system shall be provided at the SEPSS location if no other emergency lighting is present.

7.3 Heating, Cooling, Ventilating, and Humidity Control.

7.3.1 The SEPSS shall be located in an area provided with heating and cooling capable of ensuring, both during the time that normal power is available and during an emergency, that the equipment is operated within the manufacturer's ambient temperature specifications. *(See also 5.2.6.)*

7.3.2 Provisions shall be made for sufficient diffusion and ventilation of the flammable gases from the battery or other electrochemical energy storage devices to limit the concentration of flammable gas in accordance with NFPA 1 or other applicable codes.

7.3.3 Ventilation.

7.3.3.1* For SEPSS equipment using free-flowing liquid electrolyte (a.k.a. vented or flooded) batteries in which vents allow the continuous evolution and release of gases into the battery space, ventilation openings or airflow shall be situated to limit the possibility of the buildup of gas pockets in accordance with NFPA 1.

7.3.3.2 Where needed, fans used to circulate and exhaust air shall use motors designed for the application. *(See Article 480, NFPA 70.)*

7.4 Protection.

7.4.1 The room in which the EPS equipment is located shall not be used for storage purposes.

7.4.2 Where SEPSS equipment rooms or separate buildings are equipped with fire suppression, one of the following systems that is compatible with the battery or other electrochemical type shall be used:

(1) Clean agent gaseous systems
(2) Pre-action systems
(3) Other suppression systems approved by the AHJ

7.4.3 Where SEPSS equipment rooms are equipped with fire detection systems, the installation of the fire detection system shall be in accordance with applicable standards. *(See NFPA 72.)*

7.4.4 The SEPSS equipment shall be protected from voltage transients due to lightning.

7.4.5* Seismic Risk.

7.4.5.1 In seismic design categories C, D, E, and F, as determined in accordance with ASCE 7/SEI 7, *Minimum Design Loads for Buildings and Other Structures,* the equipment shall be designed to reduce the risk of failure caused by the anticipated seismic ground motion.

7.4.5.2 Components of an SEPSS shall be assigned a component importance factor of 1.5, per ASCE 7/SEI 7, *Minimum Design Loads for Buildings and Other Structures.*

7.4.5.3 The batteries shall be restrained in position, to limit the chance of spillage or breakage due to the anticipated seismic ground movement.

7.4.5.4 Outgoing bus bars and cables on battery systems shall be braced in such a manner as to limit the chance of post rupture where seismic ground movement is anticipated.

7.5 Distribution.

7.5.1 The grounding, distribution, and wiring systems within the EPS shall be installed in accordance with applicable standards. *(See NFPA 70.)*

7.5.2 The electrical distribution system within the SEPSS shall be complete with overcurrent and fault current protective equipment designed and sized for the system.

7.5.3 Overcurrent protective devices for batteries or other dc sources shall be located as close as practical to the stored-energy source to minimize possibility of fault.

7.5.4 Storage batteries used to power the SEPSS shall be located as close to the SEPSS as practicable and shall be connected using cable that is sized to limit the voltage drop to levels within the SEPSS manufacturer's specifications.

7.6 Installation Acceptance.

7.6.1 Upon completion of the installation of the SEPSS, the system shall be tested to ensure conformity with the requirements of this standard with respect to both power output and function.

7.6.2 An on-site acceptance test shall be conducted to determine final approval for all SEPSS.

7.6.2.1 For battery-based systems, the on-site test shall be conducted in the following manner:

(1) With the batteries fully charged and with a connected load bank at rated value, a normal power failure shall be initiated by opening all switches or breakers supplying the normal power to that load.
(2) All emergency loads, including those not normally energized, shall be included in the on-site test.
(3) The time delay between initiation of the power failure and the assumption of the load by the EPS shall be observed and recorded.
(4) The voltage and current supplied to the emergency load and, where applicable, the frequency, waveform, and transients shall be recorded.
(5) The load test shall be continued for 15 minutes or the rated time (class), whichever is shorter, and the following shall be observed and recorded:
    (a) Voltage and current to the load
    (b) Voltage and current of the battery bank
    (c) Where applicable, the frequency
(6) The normal power shall be restored to the monitored circuit.
(7) The transfer time shall be observed.

7.6.2.2 Immediately following the test specified in 7.6.2.1, the SEPSS shall be connected to the normal power for 24 hours. *(See 5.2.8.2.)*

7.6.2.3 System Load Test. A system load test shall be initiated following the recharge period required in 7.6.2.2.

7.6.2.3.1 The system load test shall be permitted to be performed on the site-connected load; however, a load bank shall be permitted to be used to augment the site-connected load, provided that it is sized to be equal to the ECE rating.

7.6.2.3.2 The unity power factor for an ac SEPSS shall be permitted, provided that rated load tests at the rated power factor are within the design parameters stated by the manufacturer of the SEPSS.

7.6.2.3.3 The duration of the load test shall be 100 percent of the class for which the SEPSS is rated.

7.6.2.3.4 The following procedure shall be utilized:

(1) A normal power failure shall be initiated by opening all switches or breakers supplying the normal power to that load.
(2) All emergency loads, including those not normally energized, shall be included in the on-site test.
(3) The time delay between initiation of the power failure and the assumption of the load by the EPS shall be observed and recorded.
(4) The voltage and current supplied to the emergency load and, where applicable, the frequency, waveform, and transients shall be recorded.
(5) The load test shall be continued for 15 minutes or the rated time (class), whichever is shorter, and the following shall be observed and recorded:
    (a) Voltage and current to the load
    (b) Voltage and current of the battery bank
    (c) Where applicable, the frequency
(6) The normal power shall be restored to the monitored circuit.
(7) The transfer time shall be observed.

7.6.3* Any battery cells or multicell units, transfer switches, or other system components that have failed shall be replaced and so noted on test reports or records, after which the system shall be retested.

7.6.4 The following shall be made available to the authority having jurisdiction at the time of the acceptance test:

(1) Factory test data on the completed system
(2) Battery specifications
(3) Vendor's certificate of compliance to the specification

7.6.5 Baseline Measurement. A permanently installed method of monitoring lead-acid batteries shall be permitted based on ohmic measurements.

7.6.5.1* Ohmic measurements shall be taken of every cell within the battery system after approximately 6 months of operation following the full load test described in 7.6.2.3, or 2 weeks following the most recent discharge thereafter.

7.6.5.1.1 Measurements shall be taken on a fully charged battery while float charging.

7.6.5.1.2 The data shall be recorded to establish a baseline against which all future measurements will be compared.

Chapter 8 Routine Maintenance and Operational Testing

8.1 General. The SEPSS shall have routine maintenance and operational testing based on the manufacturer's recommendations, instruction manuals, and the minimum requirements of this chapter and subject to the approval of the authority having jurisdiction.

8.2 Manuals, Special Tools, and Spare Parts.

8.2.1 At least two sets of instruction manuals for the SEPSS shall be supplied by the manufacturer of the SEPSS and shall contain the following:

(1) A detailed explanation of the operation of the system
(2) A schematic wiring diagram
(3) A function block diagram
(4) The energy storage device's specification, installation instructions, maintenance information, and wiring diagrams

(5) Instructions for routine maintenance
(6) Recommended spare parts list with part numbers and part sources
(7) Routine troubleshooting procedures

8.2.2 For Level 1, one set of the instructions shall be kept with the equipment, and the other set shall be kept in another secure location.

8.2.3 Special tools and testing devices required for routine maintenance shall be available for use when needed.

8.3 Maintenance and Operational Testing.

8.3.1 The SEPSS shall be maintained so that the system is capable of supplying the service quality within the time specified for the type and for the time duration specified for the class.

8.3.2* A routine maintenance and operational testing program shall be initiated immediately following the acceptance test or any repair or component replacement, including battery replacement. *(See Table A.8.3.2 and Figure A.8.4.2 for guidance.)*

8.3.3 Reproducible Records.

8.3.3.1 A reproducible record of inspection, tests, and repairs shall be maintained on the premises. *(See Table A.8.3.2.)*

8.3.3.2 The record shall include the following:

(1) Completion of a log
(2) Notification of any unsatisfactory condition and the corrective actions taken, including parts replaced
(3) Identification of the servicing personnel
(4) Documentation of a completed test of the SEPSS, according to 8.4.1, immediately following any repair or battery replacement

8.4 Operational Inspection and Testing.

8.4.1* Level 1 equipment shall be inspected monthly and tested in accordance with the manufacturer's recommendations. *(See Figure A.8.4.2.)*

8.4.2* Inspection of the equipment shall include the following:

(1) The battery and associated charger/control equipment shall be checked to verify that they are in a clean and satisfactory condition and that no exceptional environmental or other conditions exist that could damage or affect performance.
(2) Battery electrolyte levels shall be checked, where applicable, and refilled as necessary.
(3) Terminals and intercell connectors shall be cleaned and regreased, if necessary, and cell tops shall be cleaned.
(4) Individual cell voltages shall be checked and recorded where practical.
(5) The specific gravity of pilot cells shall be checked and recorded, where applicable.
(6) The conditions of the plates and sediment of free-electrolyte, LA batteries in transparent containers shall be noted.
(7) All indicator lamps, meters, and controls shall be checked to verify that they are operating correctly.
(8) The load value shall be checked to ensure that it is within the equipment rating.

8.4.3 Load Testing.

8.4.3.1 A load test shall be performed as required by 8.4.1. The output voltage, battery voltage, and duration of the test shall be recorded at the beginning and at the end of the test for each battery set.

8.4.3.2 When a method of ohmic measurements is used to monitor LA batteries, the results shall be maintained and checked for deviance from the baseline established in 7.6.5.

8.4.3.2.1 If data indicate deviation outside an acceptable range, the battery shall be load tested for the full duration for its class.

8.4.3.2.2 A fully rated load bank shall be used in lieu of an actual load, provided it is sized to be equal to the ECE rating.

8.4.4 The SEPSS shall be tested annually by one of the following methods:

(1) At 100 percent of its rated load for 60 percent duration of its rated class
(2) At 60 percent of its rated load for 100 percent duration of its class

8.4.5 A written record of all checks and tests in 8.4.2 shall be maintained and shall be accessible to the authority having jurisdiction. *(See Figure A.8.4.2.)*

8.4.6 The routine maintenance and operational testing program shall be performed by qualified personnel.

Annex A Explanatory Material

Annex A is not a part of the requirements of this NFPA document but is included for informational purposes only. This annex contains explanatory material, numbered to correspond with the applicable text paragraphs.

A.1.1.1 This document applies to stored-energy power systems that are used in lieu of the systems defined in NFPA 110. For emergency power systems supplied by emergency generators, see NFPA 110. Such systems are regulated in Articles 700 and 701 of *NFPA 70 (NEC)*.

A.1.1.4.1 Optional standby systems are described in Article 702 of *NFPA 70 (NEC)*.

A.3.2.1 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

A.3.2.2 Authority Having Jurisdiction (AHJ). The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A.3.2.4 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A.3.3.1.1 Lead-Acid (LA) Cell. Multiple cells make up an LA battery. LA cells are often further identified by the type of lead alloy. Most common is "lead-calcium." "Lead antimony" and "lead selenium" are also used.

A.3.3.1.1.1 Valve-Regulated (VRLA). In VRLA batteries, the liquid electrolyte in the cells is immobilized in an absorptive glass mat (AGM cells or batteries) or by the addition of a gelling agent (gel cells or gelled batteries).

A.3.3.1.1.2 Vented (Flooded). Flooded lead-acid batteries have a provision for the user to add water to the cell and are equipped with a flame-arresting vent that permits the escape of hydrogen and oxygen gas from the cell in a diffused manner such that a spark, or other ignition source, outside the cell will not ignite the gases inside the cell. [**1,** 2015]

A.3.3.2 Bridging System. A bridging system is an electrical system used to support the load only long enough to allow transfer to an alternate energy source (such as an emergency or standby generator, fuel cells, or an alternate utility source). Common bridging systems are rotary, static, or hybrid UPS systems.

A.3.3.3 Electrochemical Energy Storage Device. Examples of electrochemical energy storage devices include batteries and ultracapacitors.

A.3.3.8.1 Emergency Power Supply (EPS). The supply includes all the related electrical and mechanical components of the proper size and/or capacity required for the generation of the required electrical power at the EPS output terminals.

For rotary energy converters, components of an EPS include the following:

(1) Prime mover
(2) Cooling system
(3) Generator
(4) Excitation system
(5) Starting system
(6) Control system
(7) Fuel system
(8) Lube system (if required)

For stationary fuel cell systems, components of an EPS include the following:

(1) Fuel cell stack
(2) Cooling system
(3) Fuel system (pure H_2, reformer system or natural gas)
(4) Air supply
(5) Exhaust system (cathode, purge)
(6) Starting system (batteries, ultracapacitors)
(7) Control system
(8) Power conversion system

Chemically derived stored-energy emergency supplies include, but are not limited to, batteries and fuel cells.

A.3.3.8.2 Uninterruptible Power Supply (UPS). The UPS usually monitors and tracks the voltage and frequency of the normal source. It could be the preferred or alternate source of power to the load.

A.4.1 The terms *emergency power supply systems (EPSS)* and *standby power supply systems,* as used in this standard, include such other terms as *alternate power systems, standby power systems, legally required standby systems, alternate power sources,* and other similar terms. Because this standard specifies the installation, performance, maintenance, and test requirements in terms of types, classes, categories, and levels, any one of the terms listed might be appropriate to describe the application or use, depending on the need and the preference of the parties involved.

For optional standby systems, see Article 702 of *NFPA 70 (NEC).*

A.4.2.2 Table 4.2.2 includes two types of uninterruptible power supply (UPS). UPS systems are available today that are capable of operation in more than one normal mode of operation. Typically, each normal mode will have a different input dependency characteristic, depending on whether the UPS output creates a new source of voltage and frequency or passes through to the load the same voltage and/or frequency characteristics of the input when not operating from its stored-energy source (e.g., battery). Some UPS have a single mode of operation, whereas other UPS can allow the user to select from among multiple modes of operation. The U.S. Environmental Protection Agency (EPA) has adopted the terminology of IEC 62040-3, *Uninterruptible Power Systems (UPS)-Part 3: Method of Specifying the Performance and Test Requirements*, which identifies the following modes of operation:

Voltage and Frequency Dependent (VFD) — Typical of an off-line UPS. Loads are supported by straight utility power until the source goes out of tolerance, at which time the UPS switches to its stored energy and inverter. VFD types typically have the best efficiency but lowest power quality. This is an example of a interruption Type U.

Voltage Independent (VI) — Typical of a line-interactive UPS, in which there could be voltage regulation, transient protection, or both, but frequency tracks the input source. VI types typically have moderate efficiency and moderate power quality. This is an example of a interruption Type U.

Voltage and Frequency Independent (VFI) — Typical of a double conversion UPS, in which both voltage and frequency are independently created by the UPS inverter. VFI types typically have somewhat lower efficiency but offer the highest power quality. This is an example of a interruption Type O.

Some UPS are able to sense a power abnormality and switch from one operating mode to another, with a time delay typically ranging from ½ to 1½ cycles. Continued operation (availability) of the load depends on the ability of its internal stored energy (e.g., capacitors) to hold it up during transfer. Only full double conversion meets Type O — all others will have some degree of transfer time that will vary depending on conditions.

A.4.3 Selection of the EPS class should take into account past outage records and fuel delivery problems due to weather and other geographic/environmental conditions. For SEPSS with batteries, the values shown in Table 4.3 assume capacity at the end of life. The end of life for lead-acid batteries is typically defined as the point at which a battery can no longer deliver 80 percent or more of its rated capacity. The end of life can vary for different types of batteries.

A.4.5 It is recognized that an SEPSS is utilized in many different locations and for many different purposes. The requirement for one application might not be appropriate for another application.

A.4.5.1 Typically, Level 1 systems are intended to automatically supply illumination, power, or both, to critical areas and equipment in the event of failure of the normal supply or in the event of damage to elements of a system intended to supply, distribute, and control power and illumination essential for safety to human life.

Level 1 systems generally are installed in places of assembly where artificial illumination is necessary for safe exiting and for panic control in buildings subject to occupancy by large numbers of people. Level 1 systems correspond to Article 700 of *NFPA 70 (NEC)* for emergency systems.

Emergency systems also can provide power for such functions as uninterruptible power supplies, ventilation where essential to maintain life, fire detection and alarm systems, public safety communications systems, industrial processes where current interruption would produce serious life safety or health hazards, and similar functions. *(See NFPA 101 and Chapter 6 of NFPA 99.)*

A.4.5.2 Typically, Level 2 systems are intended to supply power automatically to selected loads (other than those classed as emergency systems) in the event of failure of the normal source.

Level 2 systems typically are installed to serve loads such as heating and refrigeration systems, communication systems, ventilation and smoke removal systems, sewage disposal, lighting, and industrial processes that, when stopped due to any interruption of the normal electrical supply, could create hazards or hamper rescue or fire-fighting operations. Level 2 systems correspond to Article 701 of *NFPA 70 (NEC)* for legally required standby systems.

A.4.5.4 It is important to recognize that an SEPSS can react in a manner substantially different from commercial power during transient and short-circuit conditions because of the relatively small capacities of the SEPSS as compared to a commercial power source.

See ANSI C84.1, *American National Standard for Electric Power Systems and Equipment — Voltage Ratings (60 Hertz).*

A.4.5.5 A UPS has stored energy (e.g., batteries) and could function as a bridging system in an EPSS. The UPS would be classified as an optional standby system, even though it is part of the greater EPSS.

A.5.1.1.1 Other emerging battery types have potential for use in SEPSS but have yet to become widely accepted in the industry. These include, but are not limited to, sodium metal-halide, sodium sulfur, vanadium redox, polysulphide bromide, and zinc bromine.

A.5.1.2 See Figure A.5.1.2(a) and Figure A.5.1.2(b) for examples of typical flywheel and rotating EPS systems.

A.5.2.1 Bridging systems can be used where Article 700 of *NFPA 70 (NEC)* requires an auxiliary power supply.

A.5.2.1.1 The requirements of 5.2.1.1 apply specifically to those solid state (static) UPS systems intended to supply power to the emergency loads during an interruption of the main power source (usually utility power) until an alternate source of power is available (such as a standby or emergency generator per NFPA 110). The intent is to cover electronic types of stored-energy systems in which power must be restored automatically and electrically when electrical power is restored to the ECE from a stable source. Mechanical inertia systems are specifically not included in the section.

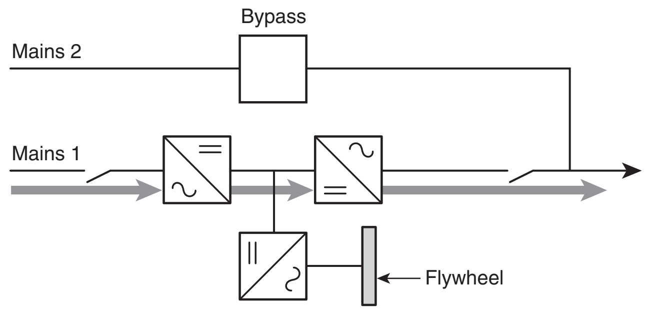

FIGURE A.5.1.2(a) UPS Using Flywheel as Energy Storage.

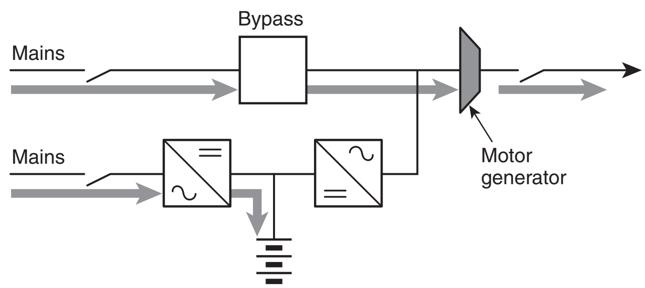

FIGURE A.5.1.2(b) Motor-Generator High Impedance Line Interactive Topology.

A.5.2.7 If the ambient temperature in the location falls below 20°C (68°F), anticondensation measures should be considered.

A.5.3.3 The minimum "remote alarm annunciation" is to alert personnel at a constantly attended station somewhere on the site when the facility is in use as a Level 1 system. If the site is not continuously occupied, "network remote" should allow people at another site to know the operating status of the equipment.

The preferred method of remote annunciation is to notify personnel both somewhere on the site and at other locations via a network such as LAN, WAN, or internet, including the ability to initiate auto-dial and send predefined text messages.

A.6.1.1 It is the intent of 6.1.1 to apply to any point in the system at which power is transferred from one point to another, such as shown in Figure A.6.1.1.

A.6.1.3 AC ratings are not suitable for dc applications. Not all overcurrent protective devices (OCPDs) are suitable for dc. Circuit breakers and/or fuses should be listed and labeled for their dc rating.

A.6.2.2 See ANSI/UL 1008, *Standard for Safety Transfer Switch Equipment.*

A.6.2.4.4 Authorized, trained personnel should be available and familiar with manual operation of the transfer switch and

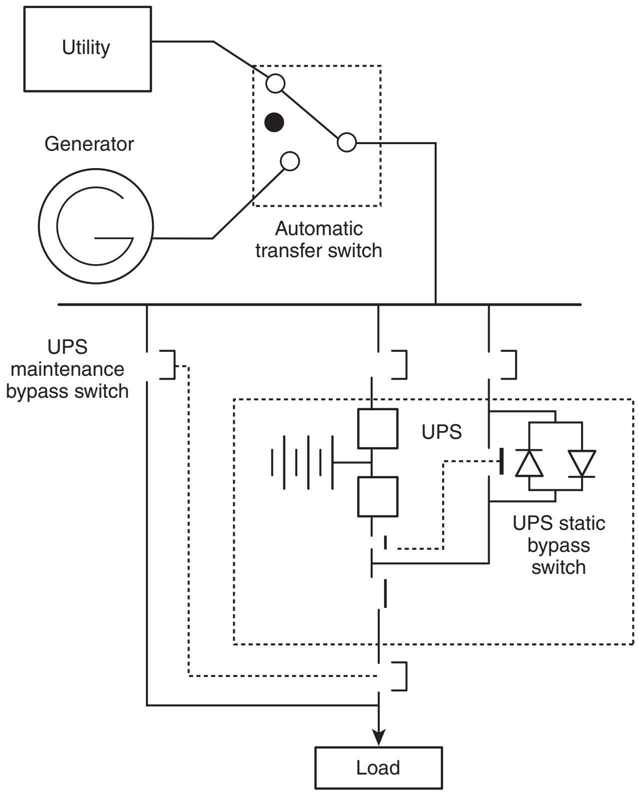

FIGURE A.6.1.1 Simplified One-Line SEPSS Switching Points.

should be capable of determining the adequacy of the alternate source of power prior to manual transfer.

A.6.2.4.5 The timer is intended to allow the preferred source of power to stabilize before retransfer of the load.

A.6.4.1 Consideration should be given to the effect that load interruption could have on the load during maintenance and service of the transfer switch.

A.6.5.1 It is extremely important that the various overcurrent devices be coordinated to protect against cascading operation on short-circuit faults. Primary consideration also should be given to prevent overloading of equipment by limiting the possibilities of large current inrushes due to instantaneous reestablishment of connections to heavy loads.

A.7.2.1 Separate rooms might be necessary for battery banks for the following reasons:

(1) Possibility of corrosion
(2) Ventilation for hazardous gas accumulation
(3) Service requirements

A.7.3.3.1 Battery rooms frequently house vented lead-acid (VLA) or nickel-cadmium (NiCd) batteries that evaporate electrolyte gas into the battery space, thereby requiring periodic water replenishment. Valve regulated lead-acid (VRLA) batteries, by contrast, vent immeasurable amounts of flammable gas under normal conditions, but they can also vent significant amounts of gas under certain failure modes such as thermal runaway. Battery manufacturers can provide guidance on the rate of gassing. All batteries require some ventilation.

A.7.4.5 Consideration should be given to the location of the emergency conversion equipment (ECE), both as it relates to the building structure and to the effects of an earthquake.

All emergency power equipment support or subsupport systems should be designed and constructed so that they can withstand anticipated static or dynamic seismic forces, or both, in any direction, with the minimum force value used being equal to the equipment weight.

Bolts, anchors, hangers, braces, and other restraining devices should be provided to limit earthquake-generated differential movements between the ECE nonstructural equipment and the building structure. However, the degree of isolation necessary for vibration and acoustical control of the ECE and other equipment should be maintained.

Suspended items such as piping, conduit, ducts, and other auxiliary equipment related to the emergency power supply system (EPSS) should be braced in two directions to resist swaying and excessive movement resulting from seismic ground motion.

Battery racks for ECE and electrical items or related auxiliaries, or both, should be designed to resist internal damage and damage at the equipment supports resulting from seismic ground motion.

Battery racks should be capable of withstanding seismic forces in any direction equal to the supported weight. Batteries should be restrained to their support to prevent vibration damage, and electrical interconnections should be provided with adequate slack to accommodate all relative deflections.

A.7.6.3 Any component of an SEPSS that has failed — not just battery components — should be replaced. If elements of the system have failed and been replaced, the SEPSS should be retested to ensure proper performance before being put into service. If battery cells or units have been replaced, the replacement cells should be torqued, charged, and balanced in accordance with the manufacturer's recommendations.

A.7.6.5.1 Case studies show that battery units are too unstable to get meaningful ohmic data when they are first installed. After a battery has been installed for some period of time (typically 6 months or longer), reliable baseline data can be taken. The actual stabilization time can vary depending upon a number of variables, including the number of discharge/recharge cycles that occur.

A.8.3.2 Maintenance procedures and frequency should follow those recommended by the manufacturer. In the absence of such recommendations, Table A.8.3.2 indicates suggested procedures.

A.8.4.1 The following standards should be consulted for recommendations on battery inspection, testing, and maintenance:

(1) IEEE 450, *Recommended Practice for Maintenance, Testing, and Replacement of Vented Lead-Acid Batteries for Stationary Applications*
(2) IEEE 1106, *Recommended Practice for Maintenance, Testing, and Replacement of Vented Nickel-Cadmium Batteries for Stationary Applications*
(3) IEEE 1188, *Recommended Practice for Maintenance, Testing and Replacement of Valve-Regulated Lead-Acid Batteries for Stationary Applications*

For other battery chemistries, refer to the manufacturer's recommendations.

A.8.4.2 Figure A.8.4.2 provides guidance for operation and testing.

Table A.8.3.2 Suggested Maintenance Schedule for Solid-State Emergency Power Supply Systems

Item Component (as Applicable)	Procedure: Visual Inspection	Check	Change	Clean	Test	Frequency
Battery						
Float voltage		X				M
Cable connections		X				S
Terminals				X		Q
Electrolyte gravity					X	Q
Electrolyte level	X					M

FIGURE A.8.4.2 Stored-Energy Emergency Power Supply System Operation and Suggested Testing Log.

Annex B Diagram of SEPSS Versus EPSS Use of Stored-Energy System

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

B.1 Figure B.1(a) through Figure B.1(d) show an uninterruptable power supply (UPS) being used in different functions.

Figure B.1(a) distinguishes the use of a stored-energy system as an SEPSS from a stored-energy system being supplied from an EPSS.

Figure B.1(b) shows a UPS being used as a stored-energy emergency power supply system (SEPSS), which is fully within the scope of this standard.

Figure B.1(c) shows a UPS being used as a bridge (also known as an auxiliary power unit) in combination with a generator emergency power supply (EPS), which is within the scope of NFPA 110. A bridge UPS is optional within NFPA 111, unless it is required for an emergency power supply that takes longer than ten seconds to start. A bridge's stored energy (e.g., battery) does not have the same reserve time as the EPS that it supports. However, because it is a component in an emergency power supply system, it is inspected and tested as part of the EPSS.

Figure B.1(d) shows a UPS being used as an optional standby power system where life safety does not depend on the performance of the system. As such, it is outside the scope of this standard.

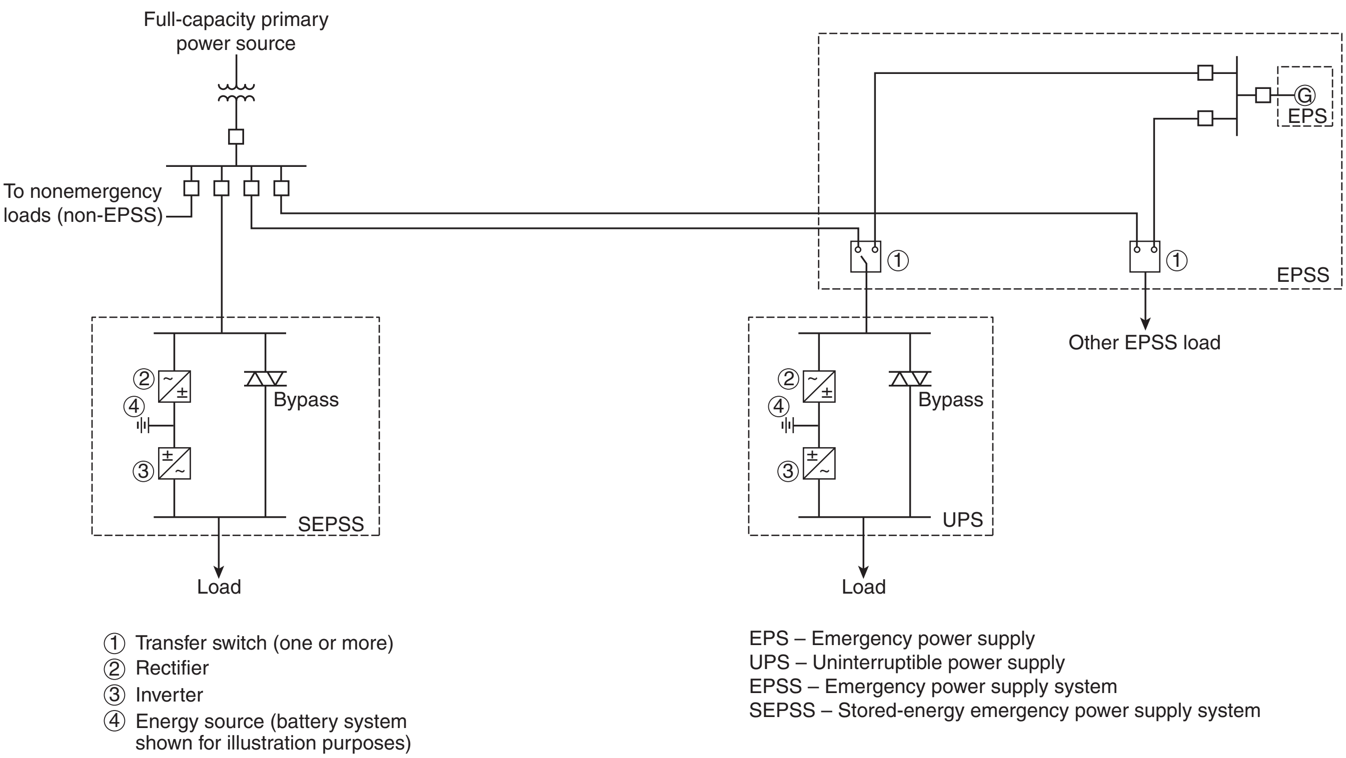

FIGURE B.1(a) Stored-Energy System Serving as SEPSS (Shown on Left) and as Equipment Supplied Through an EPSS (Shown on Right).

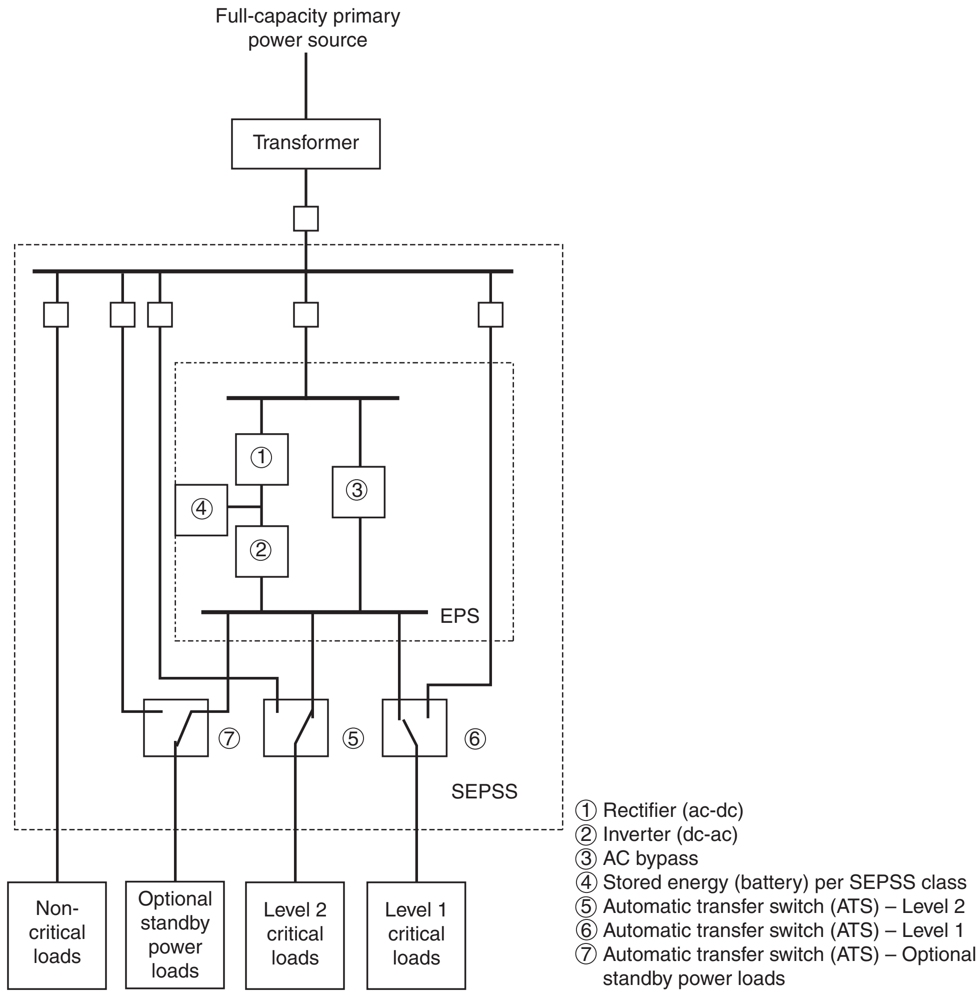

FIGURE B.1(b) Simplified Diagram Showing a Stored-Energy Emergency Power Supply System (SEPSS).

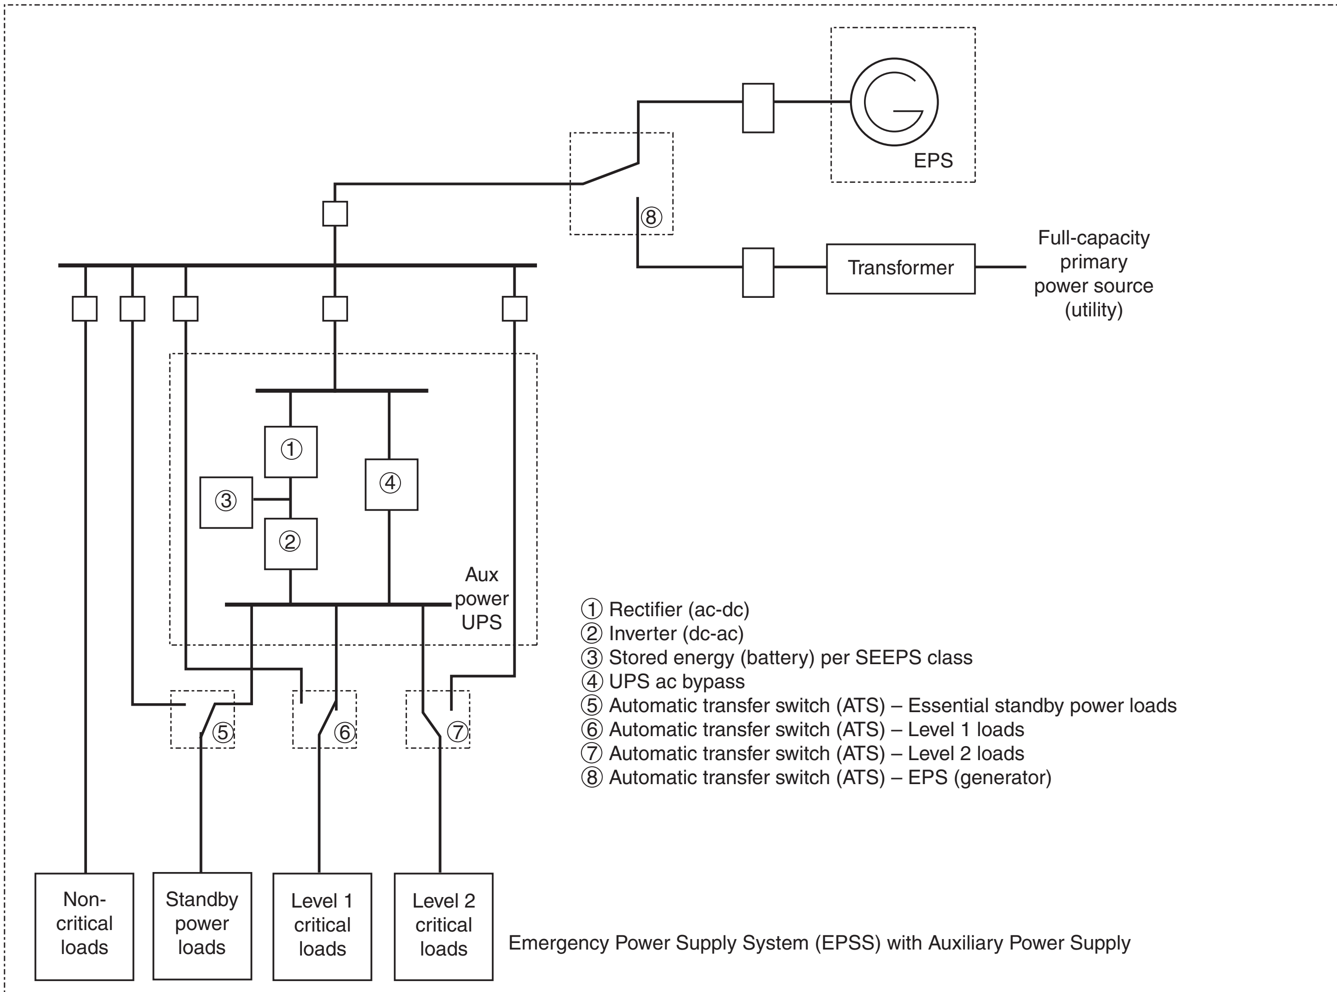

FIGURE B.1(c) Simplified Diagram Showing a UPS Used as a Bridge (a.k.a. an Auxiliary Power Unit) within an Emergency Power Supply System (EPSS).

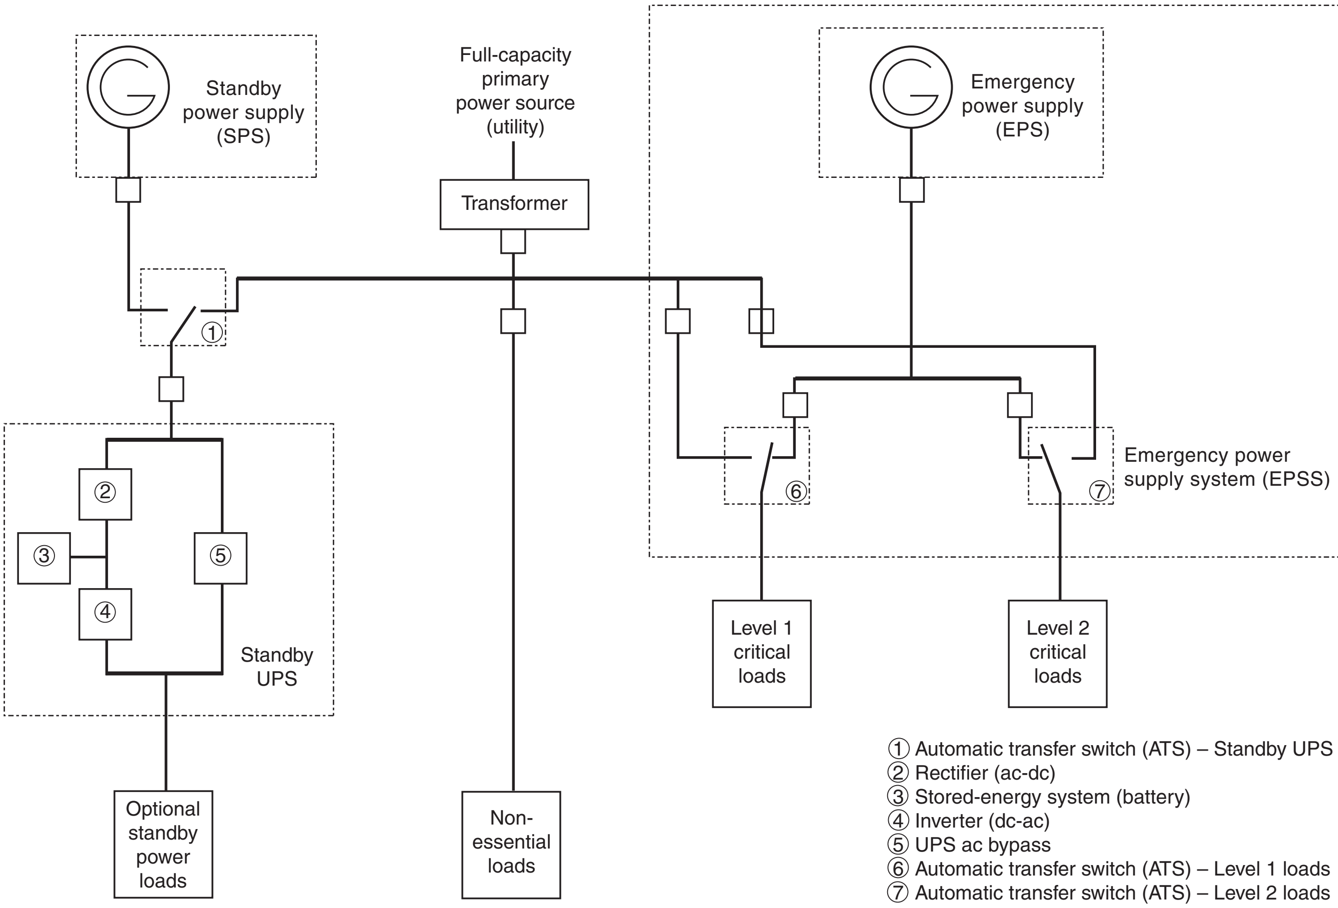

FIGURE B.1(d) Simplified Diagram for an Emergency Power Supply System (EPSS) and a Standby UPS.

NFPA® 115

Standard for

Laser Fire Protection

2016 Edition

This edition of NFPA 115, *Standard for Laser Fire Protection*, was prepared by the Technical Committee on Laser Fire Protection. It was issued by the Standards Council on January 28, 2015, with an effective date of February 17, 2015, and supersedes all previous editions.

This edition of NFPA 115 was approved as an American National Standard on February 17, 2015.

Origin and Development of NFPA 115

In September 1988, a request was received by the NFPA Standards Council to establish a project on laser fire protection. At that time, NFPA documents did not address the fire hazards of lasers. Existing non-NFPA standards addressed other laser hazards (primarily health hazards) but did not adequately address the fire hazards involved. In October 1988, the Council published a request for comments on the need for such a project. After reviewing comments submitted, the Council approved the establishment of a laser fire protection project in July 1989. The resultant document (designated NFPA 115) was intended to supplement existing NFPA documents and other standards involving lasers. Where a particular hazard, such as a flammable liquid, was appropriately addressed by another NFPA document, that document was referenced.

Lasers can be a significant fire hazard. Class 4 and some Class 3b lasers (classification is from ANSI Z136.1, *Safe Use of Lasers*) are powerful enough that the beam is an ignition hazard. During use, particularly in the medical field, the laser beam is directly adjacent to combustible materials and, in certain clinical procedures, flammable gastrointestinal gases and prepping agents. Fire incidents have occurred when the laser beam has impinged on a material other than the intended target.

Additionally, some lasers use flammable liquids as an integral part of their operation. The flammable liquids are pumped and flow through tubing, which can be quartz or plastic. Both types of tubing are prone to damage, either by breaking or melting, when exposed to a fire. When this occurs, a flammable liquid pool fire is created.

Materials used to fabricate laser systems are often inappropriate with respect to fire safety — that is, manufacturers do not always choose component materials with regard to their ignition and heat-release properties. Lasers can involve the use of high-energy power supplies. Motors for use with flammable liquids need to be intrinsically safe or of approved electrical classification.

As part of an ongoing effort to document the fire hazards of lasers, there is a database of fires involving lasers. (Documented incidents have occurred in hospitals, research laboratories, and industrial applications.) According to the data gathered thus far, the majority of incidents involve the laser beam as the ignition source. Materials ignited include adjacent combustibles as well as components of the laser itself. Other incidents have involved components of the laser overheating or igniting due to a failure of the laser system.

In the 1999 edition of this document, changes were made to conform to the NFPA *Manual of Style*. In addition, many of the references to "flammable" liquids were changed to "ignitible" liquids because "flammable" was too restrictive.

In the 2003 edition, the document changed from a recommended practice to a standard. Therefore, all of the language within the body of the document was changed to enforceable language, and any recommendations or advisory information was moved to the annexes.

The 2008 edition was revised in order to stay current with all other NFPA documents. The definitions were updated and the language was changed where appropriate, in order to add

NFPA and National Fire Protection Association are registered trademarks of the National Fire Protection Association, Quincy, Massachusetts 02169.

clarity. A new requirement was added, which called for fire training for health care facilitators wherever a patient may be in contact with lasers.

The 2012 edition was updated and definitions changed in accordance with the *NFPA Glossary of Terms*. The language was clarified for pre-fire planning for staff members to be trained and knowledgeable in emergency procedures.

The 2016 edition has been updated with the current references and definitions in accordance with the NFPA *Glossary of Terms*. In addition to the language being revised to clarify requirements, the list of degraded components that could lead to a fire in the Performance Monitoring section was updated.

Technical Committee on Laser Fire Protection

Sharon S. Gilyeat, *Chair*
Koffel Associates, Inc., MD [SE]

Daniel Capostagno, SPI Lasers, CA [M]
Richard L. P. Custer, Arup Fire, MA [SE]
Sean Frenette, Hartford Healthcare, CT [U]
Daniel J. Hewett, U.S. Food and Drug Administration, MD [E]
William J. Pate, University of Texas Medical Branch, TX [U]
Gary C. Rosenfield, RCS Rocket Motor Components, Inc./Survival Laser, Inc., UT [M]
Fred P. Seeber, Laser Institute of Technology, NJ [U]
Karl R. Umstadter, KLA-Tencor, CA [M]
Jeffrey Webb, Boulder Rural Fire Protection District, CO [E]

Jacqueline R. Wilmot, NFPA Staff Liaison

This list represents the membership at the time the Committee was balloted on the final text of this edition. Since that time, changes in the membership may have occurred. A key to classifications is found at the back of the document.

NOTE: Membership on a committee shall not in and of itself constitute an endorsement of the Association or any document developed by the committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on fire protection for laser equipment, including their safe installation, use, and maintenance.

NFPA 115

Standard for

Laser Fire Protection

2016 Edition

IMPORTANT NOTE: This NFPA document is made available for use subject to important notices and legal disclaimers. These notices and disclaimers appear in all publications containing this document and may be found under the heading "Important Notices and Disclaimers Concerning NFPA Standards." They can also be obtained on request from NFPA or viewed at www.nfpa.org/disclaimers.

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates that explanatory material on the paragraph can be found in Annex A.

A reference in brackets [ ] following a section or paragraph indicates material that has been extracted from another NFPA document. As an aid to the user, the complete title and edition of the source documents for extracts in mandatory sections of the document are given in Chapter 2 and those for extracts in informational sections are given in Annex F. Extracted text may be edited for consistency and style and may include the revision of internal paragraph references and other references as appropriate. Requests for interpretations or revisions of extracted text shall be sent to the technical committee responsible for the source document.

Information on referenced publications can be found in Chapter 2 and Annex F.

Chapter 1 Administration

1.1 Scope.

1.1.1 This document shall provide minimum fire protection requirements for the design, manufacture, installation, and use of lasers and associated equipment.

1.1.2 Criteria for training for and responding to fire emergencies involving lasers shall be included.

1.2 Purpose. This document shall provide requirements intended to prevent or mitigate the effects of fire involving lasers.

1.3 Application. This document shall apply to lasers capable of producing a beam ignition hazard, lasers utilizing materials or components presenting a fire hazard, and the areas where such lasers are used.

1.4 Retroactivity. The provisions of this standard reflect a consensus of what is necessary to provide an acceptable degree of protection from the hazards addressed in this standard at the time the standard was issued.

1.4.1 Unless otherwise specified, the provisions of this standard shall not apply to facilities, equipment, structures, or installations that existed or were approved for construction or installation prior to the effective date of the standard. Where specified, the provisions of this standard shall be retroactive.

1.4.2 In those cases where the authority having jurisdiction determines that the existing situation presents an unacceptable degree of risk, the authority having jurisdiction shall be permitted to apply retroactively any portions of this standard deemed appropriate.

1.4.3 The retroactive requirements of this standard shall be permitted to be modified if their application clearly would be impractical in the judgment of the authority having jurisdiction, and only where it is clearly evident that a reasonable degree of safety is provided.

1.5 Equivalency. Nothing in this standard is intended to prevent the use of systems, methods, or devices of equivalent or superior quality, strength, fire resistance, effectiveness, durability, and safety over those prescribed by this standard.

1.5.1 Technical documentation shall be submitted to the authority having jurisdiction to demonstrate equivalency.

1.5.2 The system, method, or device shall be approved for the intended purpose by the authority having jurisdiction.

1.6 Interface with Existing Codes and Standards.

1.6.1 When interface with existing NFPA or other consensus codes and standards occurs, reference shall be made in the text to the appropriate source.

1.6.2 Due to the unique fire hazards associated with lasers and their operations, this standard shall provide additional fire safety requirements beyond that of other documents.

Chapter 2 Referenced Publications

2.1 General. The documents or portions thereof listed in this chapter are referenced within this standard and shall be considered part of the requirements of this document.

Chapter 3 Definitions

3.1 General. The definitions contained in this chapter shall apply to the terms used in this standard. Where terms are not defined in this chapter or within another chapter, they shall be defined using their ordinarily accepted meanings within the context in which they are used. *Merriam-Webster's Collegiate Dictionary,* 11th edition, shall be the source for the ordinarily accepted meaning.

3.2 NFPA Official Definitions.

3.2.1* Approved. Acceptable to the authority having jurisdiction.

3.2.2* Authority Having Jurisdiction (AHJ). An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

3.2.3 Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

3.2.4* Listed. Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

3.2.5 Shall. Indicates a mandatory requirement.

3.2.6 Should. Indicates a recommendation or that which is advised but not required.

3.2.7 Standard. An NFPA Standard, the main text of which contains only mandatory provisions using the word "shall" to indicate requirements and that is in a form generally suitable for mandatory reference by another standard or code or for adoption into law. Nonmandatory provisions are not to be considered a part of the requirements of a standard and shall be located in an appendix, annex, footnote, informational note, or other means as permitted in the NFPA Manuals of Style. When used in a generic sense, such as in the phrase "standards development process" or "standards development activities," the term "standards" includes all NFPA Standards, including Codes, Standards, Recommended Practices, and Guides.

3.3 General Definitions.

3.3.1* Accessible Emission Limit (AEL). The maximum accessible emission level permitted within a particular class.

3.3.2* Beam. A collection of rays that can be parallel, divergent, or convergent.

3.3.3 Beam Intensity Profile (Irradiance Distribution). A description of the variations that can be present in the cross-section of a laser beam or in a focused laser spot.

3.3.4* Continuous Wave (cw). The output of a laser operated in a continuous rather than a pulsed mode.

3.3.5* Energy. The capacity for doing work.

3.3.6* Explosion. The sudden conversion of potential energy (chemical, mechanical, or nuclear) into kinetic energy that produces and violently releases gas.

3.3.7* Flammable Liquid Storage Cabinet. A cabinet for the storage of flammable and combustible liquids.

3.3.8 Flammable Vapors. A concentration of constituents in air that exceeds 25 percent of its lower flammable limit (LFL).

3.3.9* Flash Point. The minimum temperature at which a liquid or a solid emits vapor sufficient to form an ignitible mixture with air near the surface of the liquid or the solid.

3.3.10 Gas.

3.3.10.1 ***Compressed Gas.*** Any material or mixture having, when in its container, an absolute pressure exceeding 40 psi (an absolute pressure of 276 kPa) at 21.1°C (70°F) or, regardless of the pressure at 21.1°C (70°F), having an absolute pressure exceeding 104 psi (an absolute pressure of 717 kPa) at 54.4°C (130°F).

3.3.10.2 ***Flammable Gas.*** Any substance that exists in the gaseous state at normal atmospheric temperature and pressure and is capable of being ignited and burned when mixed with the proper proportion of air, oxygen, or other oxidizers. [**99,** 2015]

3.3.10.3* ***Reactive Gas.*** A gas that, by itself, is readily capable of detonation, explosive decomposition, or explosive reaction at normal or elevated temperatures and pressures.

3.3.11* Hazardous Chemical. A chemical with one or more of the following hazard ratings as defined in NFPA 704: Health — 2, 3, or 4; Flammability — 2, 3, or 4; Reactivity — 2, 3, or 4.

3.3.12 Facility Fire Brigade. An organized group of employees at a facility who are knowledgeable, trained, and skilled in at least basic fire-fighting operations, and whose full-time occupation might or might not be the provision of fire suppression and related activities for their employer. [**600,** 2015]

3.3.13 Irradiance. The power of a laser divided by the area of the laser beam at the target surface, expressed in watts per centimeter squared (W/cm^2).

3.3.14* Joule. The preferred SI unit of heat, energy, or work. [**921,** 2014]

3.3.15 Laboratory Apparatus. Furniture, laboratory hoods, centrifuges, refrigerators, and commercial or made-on-site equipment used in a laboratory.

3.3.16* Laser. A device that produces an intense, coherent, directional beam of light by stimulating electronic or molecular transitions to lower energy levels (an acronym for Light Amplification by Stimulated Emission of Radiation).

3.3.16.1 ***Embedded Laser.*** An enclosed laser with an assigned class number higher than the inherent capability of the laser system in which it is incorporated, where the system's lower classification is appropriate due to the engineering features limiting accessible emission.

3.3.16.2 ***Pulsed Laser.*** A laser that delivers its energy in the form of a single pulse or a train of pulses; a single pulse or a train of pulses with a pulse duration of <0.25 second.

3.3.16.3 ***Q-Switched Laser.*** A laser that emits short (approximately 10 to 250 nanoseconds), high-power pulses by means of a Q-switch.

3.3.17* Laser Safety Personnel (LSP). One who has authority to monitor and enforce the control of laser hazards and to effect the knowledgeable evaluation and control of laser hazards.

3.3.18* Laser System. An assembly of electrical, mechanical, and optical components that includes a laser.

3.3.19 Lecture Bottle. A small compressed gas cylinder with a physical volume of less than 500 cm^3.

3.3.20 Liquid. Any material that (1) has a fluidity greater than that of 300 penetration asphalt when tested in accordance with ASTM D5, *Standard Test Method for Penetration of Bituminous Materials*, or (2) is a viscous substance for which a specific melting point cannot be determined but that is determined to be a liquid in accordance with ASTM D4359, *Standard Test for Determining Whether a Material Is a Liquid or a Solid.* [**30,** 2015]

3.3.20.1 ***Combustible Liquid.*** Any liquid that has a closed-cup flash point at or above 37.8°C (100°F). [**306,** 2014]

3.3.20.1.1 ***Combustible Liquid, Class II.*** Any liquid that has a flash point at or above 100°F (37.8°C) and below 140°F (60°C). [**30:**4.3.2]

3.3.20.1.2 ***Combustible Liquid, Class IIIA.*** Any liquid that has a flash point at or above 140°F (60°C), but below 200°F (93°C). [**30:**4.3.2]

3.3.20.1.3 ***Combustible Liquid, Class IIIB.*** Any liquid that has a flash point at or above 200°F (93°C). [**30:**4.3.2]

3.3.20.2 ***Flammable Liquid.*** A liquid that has a closed-cup flash point that is below 37.8°C (100°F) and a maximum vapor pressure of 2068 mm Hg (absolute pressure of 40 psi) at 37.8°C (100°F)

3.3.20.2.1 ***Flammable Liquid Class I.*** Any liquid that has a closed-cup flash point below 37.8°C (100°F) and a Reid vapor pressure not exceeding 2068.6 mm Hg (absolute pressure of 40 psi) at 37.8°C (100°F).

3.3.20.2.2 ***Flammable Liquid Class IA.*** Any liquid that has a flash point below 22.8°C (73°F) and a boiling point below 37.8°C (100°F).

3.3.20.2.3 ***Flammable Liquid Class IB.*** Any liquid that has a flash point below 22.8°C (73°F) and a boiling point at or above 37.8°C (100°F).

3.3.20.2.4 ***Flammable Liquid Class IC.*** Any liquid that has a flash point at or above 22.8°C (73°F), but below 37.8°C (100°F).

3.3.20.3 ***Ignitible Liquid.*** Any liquid or the liquid phase of any material that is capable of fueling a fire, including a flammable liquid, combustible liquid, or any other material that can be liquefied and burn.

3.3.21 Lower Explosive Limit or Lower Flammable Limit. The minimum concentration of combustible vapor or combustible gas in a mixture of the vapor or gas and gaseous oxidant above which propagation of flame will occur on contact with an ignition source.

3.3.22* Maintenance (Laser Products). Performance by the user of those adjustments or procedures specified in user information provided by the manufacturer with the laser or laser system to ensure the intended performance of the product.

3.3.23* Maximum Allowable Working Pressure. The maximum gauge pressure permissible at the top of completed equipment, a container, or a vessel in its operating position for a design temperature. [**59A,** 2013]

3.3.24* Noncombustible. Not capable of igniting and burning when subjected to a fire.

3.3.25* Operation. The performance of the laser or laser system over the full range of its intended functions (normal operation).

3.3.26 Oxidizing Material. Any material that readily yields oxygen or other oxidizing gas or that reacts chemically to oxidize combustible materials.

3.3.27 Oxygen-Enriched Atmosphere (OEA). An atmosphere in which the concentration of oxygen exceeds 21 percent by volume or its partial pressure exceeds 21.3 kPa (160 torr). [**53,** 2011]

3.3.28* Plasma. A state of ionization in a gas, solid, or liquid that can be generated by the very high electromagnetic field strengths of focused laser beams or by the impact of high-power laser beams.

3.3.29 Power. The rate at which energy is emitted, transferred, or received; the units of power are watts (joules/second).

3.3.30 Proper(ly). In accordance with the manufacturer's specifications or as recommended by the manufacturer.

3.3.31* Protective Housing. An enclosure that surrounds the laser or laser system that prevents access to laser radiation above the applicable maximum permissible exposure (MPE) level.

3.3.32* Q-Switch. A device for producing very short (approximately 30 nanoseconds), intense laser pulses by enhancing the storage and dumping of electronic energy in and out of the lasing medium, respectively.

3.3.33* Radiant Exposure. Energy received by the surface in joules/cm^2.

3.3.34 Safety Factor. The ratio of the calculated failure pressure (or actual failure pressure, if known) to the MAWP.

3.3.35* Service (Laser Products). The performance of those procedures or adjustments described in the manufacturer's service instructions that can affect any aspect of the performance of the laser or laser system.

3.3.36 Watt (W). Unit of power, or rate of work, equal to one joule per second, or the rate of work represented by a current of one ampere under the potential of one volt. [**921,** 2014]

Chapter 4 Classification of Lasers

4.1 Classification Methods. Lasers shall be classified in accordance with International Electrotechnical Commission (IEC) IEC 60825-1, *Safety of laser products — Part 1: Equipment classification, requirements and user's guide*, or 21 CFR Parts 1040.10 and 1040.11. *(See Annex D.)*

4.2 Application of Requirements. The fire protection requirements provided within this standard shall apply to the following classification of lasers:

(1) Class 3b
(2) Class 4

Chapter 5 Evaluation of Laser Beam Ignition Potential

5.1 General.

5.1.1* Continuous wave (cw) laser beams producing irradiances in the order of 0.5 W/cm^2 or greater shall be considered to be ignition hazards.

5.1.2 Other factors that shall be considered with pulsed lasers include the following:

(1) Radiant exposure
(2) Pulse duration
(3)*Pulse repetition rate

5.1.3 Class 4 lasers shall always be considered to be beam ignition hazards.

5.1.4* Lasers in the upper power and energy levels of Class 3b shall be considered as beam ignition hazards if the irradiance is greater than 0.5 W/cm^2.

5.2 Factors Affecting Ignition Potential. Factors affecting ignition potential shall include the following:

(1) Irradiance at the fuel, duration of exposure, and nature of the fuel
(2) Low irradiance laser beams capable of being focused to an irradiance sufficient to cause ignition
(3) Irradiance and the exposure time at the target
(4) Oxygen-enriched atmospheres
(5) Target thickness
(6) Irradiance modalities capable of generating plasma

Chapter 6 Laser Beam Ignition

6.1 General. Before a laser is used, the alignment shall be verified, the appropriate beam stop materials shall be in place, and the facility, control measures, safety, and training programs shall be established in accordance with ANSI Z136.1, *Safe Use of Lasers.*

6.2 Before Using Laser.

6.2.1 Beam Alignment. If an alignment beam is present, proper coincidence with the treatment beam shall be verified in accordance with the manufacturer's recommendations.

6.2.2 Beam Stop Materials. Before the laser is used, it shall be determined that the appropriate beam stop materials are in place.

6.3 Education.

6.3.1 Health Care.

6.3.1.1 Education shall be in accordance with that stated in ANSI Z136.3, *Safe Use of Lasers in Health Care Facilities.*

6.3.1.2* Detailed training in laser safety shall be required for those health care personnel who use a medical laser or are responsible for patient care during the use of a medical laser.

6.3.1.3 Training shall include extinguishing laser fires when a patient is directly involved in a laser fire event.

6.3.2 Other. Education shall be in accordance with that stated in ANSI Z136.1, *Safe Use of Lasers.*

6.4 Facility.

6.4.1 Health care facilities where laser systems are used shall comply with the following:

(1) ANSI Z136.3, *Safe Use of Lasers in Health Care Facilities*
(2) NFPA *101*, for detection, suppression, and means of egress
(3) NFPA 99, for electrical systems, electrical equipment, gas and vacuum systems, and gas equipment

6.4.2 Other. Facilities where laser systems are used shall comply with the following:

(1) ANSI Z136.1, *Safe Use of Lasers*
(2) NFPA *101*, for detection, suppression, and means of egress
(3) *NFPA 70*

6.4.3 Flammable and Combustible Conditions.

6.4.3.1 Nothing shall be considered fire safe when impinged upon by a laser beam in the presence of an oxygen-enriched atmosphere, except for the noble metals.

6.4.3.2 Potential fuels shall include, but not be limited to, the categories listed in 6.4.3.2.1 and 6.4.3.2.2.

6.4.3.2.1 Health care categories shall include the following:

(1) *Patients.* Hair, gastrointestinal gases (methane, hydrogen, and hydrogen sulfide)
(2) *Prepping Agents.* Degreasers (ether, acetone, aerosol adhesives, alcohol), tinctures (Hibitane™, Merthiolate™, collodion, benzoin)
(3) *Fabric Products.* Towels, surgical drapes, dressings, gowns, masks, shoe covers, caps/hoods, gauze, sponges, patient warming devices
(4) *Plastic/Rubber Products.* Surgical drapes, gloves, anesthesia masks, tracheal tubes, breathing circuits, patient warming devices
(5) *Ointments.* Petroleum-based jelly
(6) *Laser Circuitry.* Beam tubes, fiber-optic cables

6.4.3.2.2 Gas categories shall include the following:

(1) *Flammable Gases.* Flammable gastrointestinal gases such as methane, hydrogen, and hydrogen sulfide present a unique hazard. Precautions to eliminate or manage these gases shall be taken.
(2) *Oxidizing Gases.* Ignition can be enhanced by the use of oxygen-enriched atmospheres that are created by the use of respiratory or anesthetic gases, or both — for example, oxygen and nitrous oxide.
(3) *Nonflammable Gases.* Nonflammable anesthetic gases and vapors have replaced flammable anesthetic gases and vapors in the United States.

Chapter 7 Fire Safety Requirements for Laser Equipment

7.1 General. Selection of materials used in the construction of the laser shall include consideration of fire safety requirements for the following:

(1) Circuit boards and support structures
(2) Acoustical, thermal, and electrical insulation
(3) Cabinetry
(4) Cooling equipment
(5) Control equipment

7.2 Laser Equipment Employing Ignitible Liquids or Flammable Gases.

7.2.1 Laser equipment employing ignitible liquids shall have a means to control or contain ignitible liquid spills using noncombustible materials.

7.2.2 When ignitible solvents are used, such as in dye lasers, products with the highest possible flash point consistent with the necessary solvent properties shall be used.

7.2.3 Laser equipment having oil-cooled components shall employ a nonflammable fluid or a fluid with the highest flash point and ignition temperature that is consistent with the necessary coolant properties.

7.2.4* Pumps, motors, and other electrical components in laser equipment that employ ignitible liquids or flammable gases shall be of intrinsically safe design or shall be appropriately rated for the application.

7.2.5 Tubing.

7.2.5.1 Metal tubing shall be used for ignitible liquids or flammable gases.

7.2.5.2 Plastic tubing shall be permitted provided it has a pressure rating of 1.5 times the maximum allowable working pressure, be of a material with the highest melting point and ignition temperature consistent with other necessary properties, and be of the shortest length possible.

7.3* Materials of Construction.

7.3.1 The use of combustible materials shall be minimized.

7.3.2 Materials used inside the laser equipment enclosure shall be evaluated for ignition and heat release properties.

7.4 Laser Equipment Ventilation. Exhaust from laser enclosures shall be directed to an area where the exhaust will not cause unacceptable damage if a fire occurs inside the laser enclosure.

7.5 Alarms and Controls.

7.5.1 Circuits.

7.5.1.1 Laser systems utilizing materials and components that present a fire hazard shall incorporate circuitry that can be used for emergency shutdown by fire detection systems, manually, or by other means.

7.5.1.2 The design of the circuit shall not permit automatic restart with restoration of power following a remote shutdown.

7.5.1.3 The design of the circuit shall not allow automatic restart until the fire detection system or manual alarm system has been reset.

7.5.2 Coolants and Ignitible Liquids.

7.5.2.1 The temperature of coolants and ignitible liquids shall be monitored to warn of excessive rate of heating or approach to threshold temperature.

7.5.2.2 Provisions shall be made for alarm and automatic shutdown should such conditions be detected.

7.5.3* Monitors.

7.5.3.1 The laser equipment cabinet or exhaust shall be monitored for the presence of pre-combustion products, such as hydrogen chloride or submicron particulate, that can be produced by component overheating or from products of combustion.

7.5.3.2 Multiple alarm thresholds such as "warning," "alarm," and "automatic shutdown" shall be considered.

7.5.4 Performance Monitoring.

7.5.4.1 Degradation of components that lead to a fire shall be monitored according to parameters that shall include one or more of the following:

(1) Component temperature
(2) Device electrical parameters (current, voltage)
(3) Laser power
(4) Frequency or magnitude of power excursions
(5) Light leakage or scatter

7.5.4.2 The monitoring function shall be accomplished by automatic or manual means at time intervals determined by the manufacturer.

7.6 Manuals and Training.

7.6.1 Fire safety features and fire hazards specific to the systems shall be included in manufacturers' instructions on laser system operations.

7.6.2 Manufacturers' instructions shall provide guidance for dealing with fire emergencies and the post-fire testing and restoration of the equipment.

7.6.3 Laser system users and service staff shall be trained on the laser system fire safety features and procedures for responding to fire emergencies prior to the user's first use and shall continue ongoing training in accordance with ANSI Z136.1, *Safe Use of Lasers*.

Chapter 8 Flammable Gases

8.1 General.

8.1.1 The general requirements of NFPA 55 shall be followed.

8.1.2 To determine if a gas is flammable, the rating as listed in CGA V-1, *Standard for Compressed Gas Cylinder Valve Outlet and Inlet Connections*, shall be used.

8.2 Work Practices.

8.2.1 Laser systems utilizing or containing flammable gas(es) shall be so labeled.

8.2.2 Gas shutdown capability shall be provided both at the location of use and remotely.

8.2.3 "Flammable Gas — No Smoking" signs shall be posted conspicuously near the supply and usage locations of the flammable gases.

8.2.4 Piping for flammable gases shall be capped when not in use.

8.2.5 No modifications shall be made to pressure containers or pressure relief devices by anyone except the supplier.

8.2.6 Systems shall be regularly maintained as recommended by the manufacturer.

8.3 Fire Safety.

8.3.1 Combustible gas sensors shall be located near the area of use of the flammable gases except where demonstrated by calculation that 25 percent of the lower explosive limit (LEL) cannot be reached if the entire contents were to discharge.

8.3.2 If the supply of flammable gases is located indoors, combustible gas sensors shall be used except where demonstrated by calculation that 25 percent of the LEL cannot be reached if the entire contents were to discharge.

8.3.3 When installed, combustible gas sensors shall be interlocked with the ventilation system and the exhaust ventilation increased at 25 percent of the LEL.

8.3.4 At 25 percent of the LEL, combustible gas sensors shall sound an audible alarm.

8.3.5 At 50 percent of the LEL, the combustible gas sensors shall sound an audible alarm and automatically shut off the supply of gases.

8.4 Facilities and Equipment.

8.4.1 General.

8.4.1.1 Indoor cylinder use shall be limited to lecture bottle size unless the cylinder(s) is kept in an approved ventilated cabinet or the room is provided with sufficient ventilation to keep the gas concentration below 25 percent of the LEL if the entire contents of the cylinder(s) in use were to discharge.

8.4.1.2* Outside flammable gas supplies in excess of 11.3 m^3 (400 ft^3) shall be separated from oxidizing gases by 6.1 m (20 ft) or a 2-hour fire-rated barrier.

8.4.1.3 Flammable Gas Supplies.

8.4.1.3.1 Exterior flammable gas supply capacity shall be evaluated so as to not exceed combustibility limits if accidentally released into any closed area where supply gas lines are routed.

8.4.1.3.2 Evaluation of closed areas where combustible gas mixtures might occur shall include assessments of installed ventilation system air exchange rates and exhaust systems, if present.

8.4.1.3.3 Combustible gas sensors shall be installed in enclosed areas where flammable gases could exceed combustibility limits.

8.4.1.3.4 A combustible gas sensor alarm shall shut off the gas supply at the source and vent the gas supply lines from the enclosed area(s) to a safe location.

8.4.1.3.5 General air dynamics within the closed areas shall be evaluated for determination of location for combustible gas sensors.

8.4.1.4 Exhaust Vents.

8.4.1.4.1 Exhaust vents shall be located at least 15.3 m (50 ft) away from air intakes for hydrogen and at least 7.6 m (25 ft) for other exhaust materials.

8.4.1.4.2 When venting above a roof, piping shall be high enough to mitigate the chance of flammable gas buildup in an undesirable location.

8.4.2 Piping.

8.4.2.1 Piping shall be clean and compatible with the gas.

8.4.2.2 Piping shall be designed to a safety factor of 4 and tested to 1.5 times the MAWP.

8.4.2.3 Piping shall be pressure-tested and then leak-checked prior to initial use and after repair and modification.

8.4.2.4 Flammable gas vent lines shall be dedicated and separate from oxidizing gas vent lines and shall terminate in a safe location.

8.4.3* Regulators.

8.4.3.1* Flammable gas regulators with bonnet fittings for piping external venting shall be used in enclosed areas.

8.4.3.2 If low pressures are required, a two-stage regulator shall be used.

8.4.3.3 Flow Control.

8.4.3.3.1 A flow control valve or a supplementary valve downstream of the regulator shall be used for control of flow.

8.4.3.3.2 The regulator shall not be used as a flow control.

8.5 Electrical Requirements. Electrical circuits, devices, fixtures, and grounding in the area of a laser classified as hazardous and for direct connection of the laser shall be installed in accordance with the applicable sections of *NFPA 70*.

8.6 Training.

8.6.1 A thorough training program in emergency procedures shall be provided for all staff members working with flammable gases.

8.6.2 The training program shall include drills, fire protection features awareness, coordination with fire-fighting personnel, and knowledge of remote shutoff for gases.

Chapter 9 Reactive Gases

9.1 General. The general requirements of NFPA 55 shall be followed.

9.2 Work Practices.

9.2.1 The reactive gas system shall be labeled to identify its contents.

9.2.2 Gas shutdown capability shall be provided both at the location of use and remotely.

9.2.3 Where possible, the gas cabinet shall be located outdoors.

9.2.4 When not in use, compressed gas cylinders containing reactive gases shall be capped.

9.2.5 When connecting or disconnecting bottles, the manifold system shall be purged to minimize the effect of corrosion of the system.

9.2.6 Maintenance.

9.2.6.1 Systems shall be maintained regularly as recommended by the manufacturer.

9.2.6.2 A system data package, including a maintenance log, shall be maintained.

9.2.6.3 The data package shall include installed exhaust calibration data.

9.2.7 Reactive gases cylinders shall be located in an approved ventilated cabinet consistent with NFPA 55.

9.2.8 No modifications shall be made to pressure containers or pressure relief devices except as authorized by the supplier.

9.3 Fire Safety.

9.3.1 Written procedures shall be followed for cylinder changing and maintenance.

9.3.2 A limiting orifice shall be installed on each cylinder to limit the release rate of the gas.

9.3.3* Gas Cabinets.

9.3.3.1 Gas cabinets shall be provided with a sprinkler system inside of the cabinet and shall be protected from corrosion where necessary.

9.3.3.2 Sprinkler installation shall comply with NFPA 13.

9.3.4 Gas Quantity and Concentration.

9.3.4.1 Only the smallest quantity or percent of reactive gas necessary shall be used.

9.3.4.2 Premixed gases shall be used to minimize the need for highly concentrated reactive gases.

9.3.5 The regulator chosen for use shall be compatible with the reactive gas.

9.4 Facilities and Equipment.

9.4.1 General.

9.4.1.1 When the ventilated cabinet is located indoors, connecting the cabinet to emergency power shall be considered to ensure continued exhaust capability.

9.4.1.2 Laser system exhaust shall be diluted to below reactive levels or mixed with an inert gas.

9.4.1.3 Exhaust systems shall be designed to ensure that the exhaust does not stagnate in exhaust piping.

9.4.1.4 The supply control valve shall be a solenoid valve designed to close in the event of loss of electrical power.

9.4.1.5 Exhaust.

9.4.1.5.1 The piping exhaust shall be located at least 7.6 m (25 ft) away from air intakes.

9.4.1.5.2 When venting above a roof, piping shall be high enough to minimize the possibility of reactive gas buildup in an undesirable location.

9.4.2 Piping.

9.4.2.1 Piping shall be clean and compatible with the gas.

9.4.2.2 Piping shall be designed to a safety factor of 4 and tested to 1.5 times the MAWP.

9.4.2.3 Piping shall be pressure-tested and leak-checked prior to initial use and after repair and modification.

9.4.2.4* Piping shall be purged with an inert gas during long periods of nonuse, maintenance, or servicing.

9.4.2.5 Fittings.

9.4.2.5.1 "Face-seal"–type fittings shall be considered acceptable.

9.4.2.5.2* Threaded or compression fittings shall not be used.

9.4.2.6 Traps or check valves shall be installed if there is the possibility of system contamination by other gases or foreign material.

9.4.3 Regulators.

9.4.3.1 Vents from regulators shall be piped to a safe location.

9.4.3.2 When low pressures are required, a two-stage regulator shall be used.

9.4.3.3 Regulator diaphragm failures shall be considered when locating a reactive gas regulator in an enclosed area.

9.4.3.4* Reactive gas regulators with bonnet fittings for piping external venting shall be used in enclosed areas.

9.4.3.5 Vents shall be piped to a safe location.

9.4.4 Flow Control.

9.4.4.1 A flow control valve or a supplementary valve downstream of the regulator shall be used for control of flow.

9.4.4.2 The regulator shall not be used as a flow control.

9.5 Electrical Requirements. Electrical circuits, devices, fixtures, and grounding in the area of a laser classified as hazardous and for direct connection of the laser shall be installed in accordance with the appropriate sections of *NFPA 70*.

9.6 Training.

9.6.1 A thorough training program in emergency procedures shall be provided for all staff members working with reactive gases.

9.6.2 The training program shall include drills, fire protection features awareness, coordination with fire-fighting personnel, and knowledge of remote shutoff for gases.

Chapter 10 Ignitible Liquids Used in Laser Systems

10.1* General. The requirements of this chapter shall be followed to minimize the risk of fire involving ignitible liquids.

10.2 Work Practices.

10.2.1 Signs such as "Caution: Flammable Liquids — No Smoking; No Open Flames" shall be posted in conspicuous locations in the area and at approaches to the area.

10.2.2 Lines (piping and tubing) containing flammable or combustible liquid shall be capped when not in use.

10.2.3 Flammable Liquids.

10.2.3.1 Containers of flammable liquids shall be closed and stored in a cool place.

10.2.3.2 Secondary containment for all flammable liquids shall be provided.

10.2.3.3 Each container and the flammable liquid circulation hardware shall have a label that includes the word "flammable."

10.2.4 Ignitible liquid dye solutions shall be transported in closed, labeled containers made of impact-resistant and dye solution–compatible materials.

10.2.5 Flammable and combustible liquids that are to be dispensed shall be stored in safety cans as described in NFPA 30, Chapter 9.

10.3 Fire Safety.

10.3.1 Solutions of ignitible liquids shall be kept away from heat, flames, electrical receptacles, and other sources of ignition.

10.3.2 Oxidizing materials shall be kept separate from flammable dye mixtures and ignitible liquids.

10.3.3 Waste Containment.

10.3.3.1 Flammable and combustible liquid waste shall be stored in wide-mouthed safety cans.

10.3.3.2 Containers shall be labeled "For Flammable Liquid Waste Only."

10.3.3.3 Hazardous (flammable, combustible, and corrosive) materials shall be collected and stored pursuant to 40 CFR and 49 CFR.

10.3.4 Cabinets.

10.3.4.1 Flammable- and combustible-liquid containers shall be stored in approved flammable liquid storage cabinets.

10.3.4.2 Only a working quantity of liquids shall be allowed outside such cabinets.

10.3.5 Ventilation shall be provided to prevent a buildup of ignitible vapor/air mixtures in excess of 25 percent of the LEL in areas where flammable liquids are used.

10.3.6* Equipment or activities likely to produce a static spark shall be electrically interconnected (i.e., bonded) to the grounding system in the area.

10.4 Facilities and Equipment.

10.4.1 Ignitible Liquid Dye Work Area.

10.4.1.1 The ignitible liquid dye work area shall be kept clean and orderly to minimize the fuel paths that facilitate the spread of fire.

10.4.1.2 Combustibles shall not be located adjacent to the dye circulator pump.

10.4.2 Ignitible liquid dye circulating systems shall be leak-tight.

10.4.3 Compression-type or clamped fittings shall be used for ignitible liquid lines.

10.4.4 Circulating Systems.

10.4.4.1 Ignitible liquid circulating systems and components shall be pressure tested to 1.5 times the MAWP prior to initial use.

10.4.4.2 Special attention shall be given to tubing connections.

10.4.4.3 The integrity of all tubing and connections shall be checked to ensure that degradation has not occurred.

10.4.5 Noncombustible containment pans shall be installed under pumps and reservoirs of sufficient capacity to contain the total volume of the ignitible liquid circulating system.

10.5 Electrical Requirements. Electrical circuits, devices, fixtures, and grounding in the area of a laser classified as hazardous and for direct connection of the laser shall be installed in accordance with the applicable sections of *NFPA 70*.

10.6 Large-Volume Ignitible Liquid Systems.

10.6.1 Where large-volume ignitible liquid systems [18.9 L (5 gal) or more] are used, NFPA 30 shall be followed.

10.6.2 Pressure sensors, flow sensors, or both, shall be installed to automatically turn off the circulating pumps in the event of a rupture or leak of the flow system.

10.6.3 Liquid level sensors shall be installed on the pump reservoir to detect a decrease in system liquid volume due to leak or rupture and shall be interlocked with the pumping system to shut down upon activation of the sensors.

10.6.4 Enclosed areas shall be ventilated at a rate sufficient to maintain the vapor concentration within the area at or below 25 percent of the LEL, confirmed by one of the following methods:

(1) Calculations based on the anticipated fugitive emissions as described in NFPA 30, Annex F
(2) Sampling of the actual vapor concentration under normal operating conditions as described in NFPA 30, Chapters 6, 17, and 18

10.6.5 Combustible vapor sensors shall be interlocked with exhaust ventilation and with the pumping system.

10.6.5.1 The exhaust ventilation shall switch to high speed at 25 percent of the LEL to prevent the buildup of flammable vapor concentrations.

10.6.5.2 At 50 percent of the LEL, an alarm shall sound, and the pumping system shall shut down.

10.6.6 A liquid detection device(s) shall be installed to detect leaks or spills within laser enclosures.

10.6.7 Remote Shutdown.

10.6.7.1 Remote shutdown capability for the laser pumping system (i.e., crash buttons) shall also be provided for personnel to activate in case of emergency.

10.6.7.2 The crash buttons shall be located near main exits of the area.

10.6.8 Building Construction.

10.6.8.1 Buildings or structures housing large-volume flammable liquid systems shall be of fire-resistive or noncombustible construction.

10.6.8.2 Combustible construction shall be permitted where automatic fire sprinklers or equivalent protection is provided, subject to the approval of the authority having jurisdiction.

10.6.8.3 Where walls are required for separation from other occupancies or property lines, they shall have a fire resistance rating of at least 2 hours consistent with the requirements of NFPA 30.

10.7 Spill Cleanup.

10.7.1 Ignitible liquid spills shall be mitigated pursuant to 40 CFR.

10.7.2 In the event of a large-volume ignitible liquid spill, the fire department shall be notified.

10.8* Waste Disposal. Ignitible liquids absorbed into solids, objects contaminated with ignitible liquids, and ignitible liquid dye solutions shall be managed as hazardous waste pursuant to 40 CFR.

10.9 Training.

10.9.1 Employees shall be apprised of the fire safety hazards of the materials and processes to which they are exposed. *[See 29 CFR 1910.38(b)(4)(i).]*

10.9.2 Employees shall review upon initial assignment those parts of the fire prevention plan and the procedures necessary to protect themselves in the event of an emergency.

10.9.3 The written fire prevention plan shall be kept in the workplace and made available for employee review.

10.10 Maintenance.

10.10.1 All equipment shall be maintained in accordance with manufacturers' instructions.

10.10.2 A safety inspection schedule for those portions of laser systems that could present a fire hazard shall be established.

10.10.3 A written log of these inspections shall be maintained.

Chapter 11 Operations/Administration

11.1 Safety Operations and Administration.

11.1.1 Lasers. Lasers and laser systems shall be operated and maintained in accordance with the following documents:

(1) ANSI Z136.1, *Safe Use of Lasers*, revised
(2) ANSI Z136.3, *Safe Use of Lasers in Health Care Facilities*
(3) Occupational Safety and Health Administration (OSHA) Instruction Pub 8-1.7
(4) NFPA 99, pertaining to electrical systems, electrical equipment, gas and vacuum systems, and gas equipment
(5) The Joint Commission documents
(6) State rules and standards

11.1.2 Laser Safety Officer (LSO). Where lasers presenting a fire hazard are used, specific personnel shall be designated to monitor and enforce the control of laser hazards and effect the knowledgeable evaluation and control of laser hazards.

11.1.3 Laser Modifications.

11.1.3.1 Modifications to certified or uncertified lasers shall meet all requirements of the minimum standards and shall be reviewed and approved by the LSO.

11.1.3.2 Whenever deliberate modifications are made that could change the laser class and affect the output power, operating characteristics, or fire hazards, the LSO shall specify whether any changes in control measures are required.

11.1.4 Fire-Extinguishing Agents.

11.1.4.1 Fire extinguishers shall be of a type and size to extinguish a fire occurring within the laser equipment and as a result of the laser beam.

11.1.4.2 Extinguishing agents shall be readily available to the laser location(s) and shall be maintained in accordance with NFPA 10.

11.1.4.3 The LSO shall determine the type and quality of extinguishing agents necessary for the specific laser installation(s) and shall consult with the manufacturers for their suggestions.

11.1.4.4 Training shall be provided on the use of portable fire extinguishers.

11.1.5* Fire-Resistant Materials. Materials adjacent to a laser that can be an ignition hazard shall be evaluated for their fire properties.

11.2 Housekeeping.

11.2.1 Laser equipment, systems, installation, and supporting materials and equipment shall be maintained in a clean, neat, and orderly condition.

11.2.2 Electrical and mechanical ventilation equipment shall be maintained to remain safe and fully operational.

11.2.3 The LSO shall ensure that the laser installation fully complies with the requirements of this and the referenced documents.

11.3 Maintenance and Service.

11.3.1 Maintenance shall be performed by trained personnel.

11.3.2 Service shall be performed by trained personnel.

11.3.3 Laser products certified by a manufacturer to be compliant with certain standards, such as the federal laser product performance standards of 21 CFR 1040, applicable at the date of manufacture, shall be maintained in compliance with such requirements.

11.3.4 The LSO shall ensure that regular maintenance schedules for each type of laser are established.

11.3.5 The LSO shall retain documentation of all maintenance and service performed.

11.3.6 Maintenance checks shall include all supporting equipment.

11.3.7 All electrical and mechanical systems shall be maintained in compliance with the documents listed in 11.1.1.

11.4 Training and Education.

11.4.1 A training program shall be established for staff members using and supporting the safe application of laser systems.

11.4.2 All training shall follow OSHA guidelines, ANSI Z136.1, *Safe Use of Lasers*, ANSI Z136.3, *Safe Use of Lasers in Health Care Facilities*, and ANSI Z136.5, *Safe Use of Lasers in Educational Institutions*.

11.4.3 The LSO shall ensure the necessary training records are maintained.

11.4.4 New staff members shall be trained.

11.4.5 When new lasers are introduced or existing laser systems are modified, staff members shall receive instruction on these systems.

11.4.6 The LSO shall monitor compliance with all training and education requirements.

Chapter 12 Emergency Preparedness

12.1 Pre-Fire Planning.

12.1.1 Staff members shall be trained and knowledgeable in exit locations and emergency procedures, including use of fire extinguishers and laser shutdown procedures.

12.1.2 Emergency services organizations shall be made aware of location and hazards of lasers.

12.1.3 Facility emergency response personnel shall be familiar with emergency shutdown procedures for the laser(s).

12.2 Training.

12.2.1 All staff members working with lasers shall receive instruction in the hazards of lasers and the use of fire-fighting equipment.

12.2.2 Emergency drills shall be conducted no less than once per year.

12.3 Fire Brigades. Established industrial fire brigades shall receive training on the hazards of lasers, fire-fighting tactics, and emergency shutdown procedures, in conjunction with the requirements of NFPA 600.

12.4 Emergency Shutdown.

12.4.1 A master emergency electrical shutdown switch that will immediately de-energize the laser shall be provided.

12.4.2 The switch shall be located inside or outside of each room, at the facility's discretion.

12.5 Fire Procedure. The following actions shall be considered:

(1) Alert others in the work area upon discovery of a fire.
(2) Whoever is closest to a manual fire alarm pull station, activate the alarm to alert all building occupants and summon the industrial fire brigade or fire department.
(3) Whoever is closest to the master emergency electrical shutdown switch, de-energize the laser.
(4) Use a portable fire extinguisher to contain, control, and extinguish the fire if possible.
(5) If the fire location involves medical oxidizing gases or industrial oxidizing gases, shut off the oxidizing gas supply.
(6) Simultaneously, other staff members evacuate the area of hazard.
(7) Close all doors in fire area.

Annex A Explanatory Material

Annex A is not a part of the requirements of this NFPA document but is included for informational purposes only. This annex contains explanatory material, numbered to correspond with the applicable text paragraphs.

A.3.2.1 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

A.3.2.2 Authority Having Jurisdiction (AHJ). The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A.3.2.4 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A.3.3.1 Accessible Emission Limit (AEL). This definition is extracted from ANSI Z136.1, *Safe Use of Lasers,* and 21 CFR 1040.10.

A.3.3.2 Beam. This definition is extracted from ANSI Z136.1, *Safe Use of Lasers.*

A.3.3.4 Continuous Wave (cw). In this document, a laser operation with a continuous output for a period ≥0.25 seconds is regarded as a cw laser. This definition is extracted from ANSI Z136.1, *Safe Use of Lasers.*

A.3.3.5 Energy. Energy content is commonly used to characterize the output from pulsed lasers, and is generally expressed in joules (J). This definition is extracted from ANSI Z136.1, *Safe Use of Lasers.*

A.3.3.6 Explosion. An explosion can be accompanied by a shock wave or the disruption or enclosing of material or structures, or both. An explosion might result from chemical changes such as rapid oxidation, decomposition, or runaway polymerization (usually detonations); deflagration; or detonation.

A.3.3.7 Flammable Liquid Storage Cabinet. The cabinet should be constructed in accordance with NFPA 30. Some local jurisdictions require bottom-venting of flammable liquid storage cabinets. While this is not required by NFPA 30, some manufacturers provide plugged vent connections to accommodate these local jurisdictions.

A.3.3.9 Flash Point. See Annex E.

A.3.3.10.3 Reactive Gas. Reactive gases can also be corrosive.

A.3.3.11 Hazardous Chemical. For hazard ratings of many chemicals, see NFPA *Fire Protection Guide to Hazardous Materials*.

A.3.3.14 Joule. A joule is the heat produced when one ampere is passed through a resistance of one ohm for one second, or it is the work required to move a distance of one meter against a force of one newton. There are 4.184 joules in a calorie, and 1055 joules in a British thermal unit (Btu). A watt is a joule/second. [**921,** 2014]

A.3.3.16 Laser. This definition and definitions in 3.3.16.1 through 3.3.16.3 are extracted from ANSI Z136.1, *Safe Use of Lasers*, and 21 CFR 1040.10.

A.3.3.17 Laser Safety Personnel (LSP). This definition is extracted from ANSI Z136.1, *Safe Use of Lasers*.

A.3.3.18 Laser System. This definition is extracted from ANSI Z136.1, *Safe Use of Lasers*.

A.3.3.22 Maintenance (Laser Products). It does not include *operation* or *service* as defined in this document. This definition is extracted from ANSI Z136.1, *Safe Use of Lasers*, and 21 CFR 1040.10.

A.3.3.23 Maximum Allowable Working Pressure. For a more complete definition, see Section VIII of the ASME *Boiler and Pressure Vessel Code*, Division 1, Appendix 3. [**59A,** 2013]

A.3.3.24 Noncombustible. Materials that are reported as passing ASTM E136 are considered noncombustible. *(See NFPA 220.)*

A.3.3.25 Operation. It does not include *maintenance* or *service* as defined in this document. This definition is extracted from ANSI Z136.1, *Safe Use of Lasers*, and 21 CFR 1040.10.

A.3.3.28 Plasma. Very high temperatures are associated with laser-generated plasmas that can appear as sparks, plumes, or flames.

A.3.3.31 Protective Housing. The aperture through which the useful beam is emitted is not part of the protective housing. The protective housing can enclose associated optics and a workstation and should limit access to other associated radiant energy emissions and to electrical hazards associated with components and terminals. This definition is extracted from ANSI Z136.1, *Safe Use of Lasers*, and 21 CFR 1040.10.

A.3.3.32 Q-Switch. This definition is extracted from ANSI Z136.1, *Safe Use of Lasers*.

A.3.3.33 Radiant Exposure. This definition is extracted from ANSI Z136.1, *Safe Use of Lasers*.

A.3.3.35 Service (Laser Products). It does not include *maintenance* or *operation* as defined in this document. This definition is extracted from ANSI Z136.1, *Safe Use of Lasers*, and 21 CFR 1040.10.

A.5.1.1 Lower values can be possible, particularly in an oxygen-enriched atmosphere, depending on the thickness and the physical properties of the material. See NSBIR 81-2271 and ASTM STP822.

A.5.1.2(3) Very high repetition rates can produce ignition hazards similar to cw laser beams.

A.5.1.4 Lasers in the lower power and energy levels of Class 3b are often incapable of being beam ignition hazards.

A.6.3.1.2 Those personnel include the surgeon or physician using the laser, the laser safety officer, anesthesia personnel, nursing staff, and other health care personnel as appropriate.

A.7.2.4 See Article 500 of *NFPA 70*.

A.7.3 Materials to consider include thermal and acoustical insulation, laminates, hoses, filters, and coil forms. From a fire safety design perspective, materials that have low ignition potential and low rates of heat release if ignited are most desirable. Heat release rate for a material is expressed in terms of kilowatts released for each square meter of material burning and is related to the physical and chemical or combustion characteristics of that material.

ASTM E1354 is useful for evaluating candidate materials. It is recommended that the materials being evaluated be tested at two different levels of incident flux, a low level (25 kW/m^2 to 30 kW/m^2) and a high level (55 kW/m^2 to 65 kW/m^2). Most materials will have a higher rate of heat release at the high flux. The additional test at a high flux level provides an indication of the expected heat release rate in a well-developed fire in a confined space.

Materials that have the lowest heat release rate at the high flux and the longest ignition time at low flux should be selected. If several candidate materials have similar heat release and ignition characteristics, the material with the lowest smoke production should be considered.

A.7.5.3 Significant particulate production can occur well in advance of smoldering or flaming fire. Increases in background particulate levels can indicate an incipient problem.

A.8.4.1.2 See NFPA 55 for additional information.

A.8.4.3 Regulator diaphragm failures should be considered when locating a flammable gas regulator in an enclosed area.

A.8.4.3.1 Standard gas regulators do not have these fittings and release supply gases through vent holes located in the bonnet in the event of a regulator diaphragm failure.

A.9.3.3 Some gases can be incompatible with water. Water reactivity should be evaluated.

A.9.4.2.4 A method for purging piping with inert gas is to have a series of evacuations followed by an inert gas fill.

A.9.4.2.5.2 These types of fittings can trap contaminants and be difficult to purge.

A.9.4.3.4 Standard gas regulators do not have these fittings and release supply gases through vent holes located in the bonnet in the event of a regulator diaphragm failure.

A.10.1 Dye lasers normally use a lasing medium composed of a complex fluorescent organic dye dissolved in an organic solvent. Practically all solvents suitable for dye solutions are ignitible. Some dye solutions come premixed from the manufacturer, in which case efforts should be made to determine which solvent was used for the preparation.

A.10.3.6 For example, nonpolar solvents flowing through plastic tubing can develop a static charge. As another example, a grounding wire should be incorporated into plastic tubing to dissipate static charge that can accumulate when nonpolar solvents flow through nonconducting tubing.

A.10.8 See the NFPA *Fire Protection Handbook* for a list of liquids subject to self-heating and autoignition.

A.11.1.5 Examples of fire properties to be evaluated include ignition, flame spread, and oxygen index.

A study on the flammability of surgical drapes has been described in Bauman, "Laser Drape Fires: How Much of a Risk?"

Annex B Nature of Hazards

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

B.1 Nature of Hazard. A beam ignition hazard might exist during the use of a laser — for example, in a research, commercial, industrial, military, or health care facility.

Annex C Education and Training

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

C.1 The LSO (laser safety officer), laser users, and maintenance or service personnel should be trained in laser fire safety and in recognizing fire hazards associated with the use of lasers. This training should be updated at least annually and any time there are changes in the laser use that can present different fire safety concerns. The following issues should be addressed during the training:

(1) Awareness of installed fire protection features in the facility and laser system
(2) Preplanning for fires, involving the appropriate emergency response personnel such as fire department or plant brigade
(3) Information on the location and method to shut off power, gases, and flammable liquids
(4) Understanding the role of employees in the fire safety plan for the facility (For example, are they expected to extinguish incipient fire? If so, appropriate training should be provided.)
(5) The safety hazards of the materials and procedures to which employees or emergency response personnel are exposed, with proper information and training provided

The following issues should be addressed during the training provided to health care facility laser users:

(1) Health care workers using medical lasers should be educated as to the fire safety problems associated with lasers in the surgical suite.
(2) General fire safety information can include an understanding of the classes of fires, extinguishing requirements of those classes of fires, and knowledge of the proper operation of handheld portable fire-fighting equipment.
(3) Training on the hazards found in the surgical suite with regard to combustible substances, gases, and oxygen-enriched atmospheres should be conducted on an annual basis.
(4) Training on any changes in equipment or procedures that can affect fire safety should be addressed prior to the use of such equipment or procedures.
(5) To reduce the incidence of fire, training on special hazards associated with the operative site when using a medical laser should be routinely reviewed and updated as new products or equipment are brought into the arena.
(6) Fire safety training can include the following:
    (a) The action(s) to be taken if drapes are burning
    (b) The responsibilities of the anesthesiologist
    (c) Responsibilities of each individual in the surgical suite if a patient fire develops
(7) Training on the facility's fire safety plan, location of fire alarms, location of fire-fighting equipment, and emergency evacuation should be conducted on an ongoing basis.

Annex D Classification of Lasers

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

D.1 This annex contains a brief explanation of the classification schemes for lasers. It is intended only to give an overview. The reader should consult the normative references in Chapter 4 to obtain detailed information about the laser hazard classes.

The laser safety standards in Chapter 4 have been in existence for approximately 30 years. These standards are aimed at preventing or reducing personal injuries resulting from exposure to hazardous levels of laser radiation. These standards operate by establishing hazard classes for lasers and by imposing equipment, informational, and administrative control measures that are appropriate for the degree of hazard.

Although the hazard classes were developed with respect to the potential for causing biological injury, they can also be useful as indicators of the ignition potential of the lasers. The processes by which lasers can cause biological injury are the same as those by which they can cause ignition. The big difference is that for biological injury from lasers in the visible and near-infrared spectral regions, the most sensitive organ is the eye because of the ability to focus laser spots on the retina. Although there are differences between the classes in the standards, there are more similarities than differences. There are four general classes: 1, 2, 3, and 4 (or I, II, III, and IV). With the exception of Class 4, the classes have limits, accessible emission limits (AEL), that consider power, emission duration, and beam propagation properties. Lasers are classified according to the level of laser radiation that is accessible during "operation," that is, when the laser is performing its intended function.

Class 1 (I) lasers either emit radiation at levels so low that they are not recognized to be capable of producing an injury or are more hazardous but are safely contained within a protective housing. Class 1 lasers can emit radiation anywhere in the optical spectrum with wavelengths between 180 nanometers and 1 meter. Some Class 1 lasers, however, contain embedded lasers of higher classes. An example would be Class 4 lasers contained within Class 1 laser machine tools.

Class 2 (II) lasers emit in the visible spectrum, between 400 and 700 nanometers, but at levels for which, although recognized to be hazardous to the eyes, a person's aversion to looking into a bright light source is sufficient to avoid an injury to the retina of the eye.

IEC 60825-1, *Safety of laser products — Part 1: Equipment classification, requirements and user's guide*, has, in its latest version, two subclasses, Classes 1M and 2M. These M classes mean that a biological hazard could be created for Class 1M, or increased for Class 2M, if a collecting optical instrument such as a telescope or loupe were used to view the laser radiation. It is likely that the ANSI Z136 Committee and the U.S. Food and Drug Administration (FDA) will adopt a similar classification scheme in the near future.

Class 3a lasers (Class IIIa lasers in 21 CFR 1040.10 and 1040.11 and Class 3R lasers in IEC 60825-1) are less than 5 times the level of either Class 1 or Class 2. They are recognized to be hazardous, but the degree of risk of a radiation injury is considered to be too low to justify severe control measures.

In addition to the biological hazard, Classes 3b and 4 possess potential for ignition.

Class 3b (IIIb) has a large range. At the low end, Class 3b lasers are considered to have a reasonable potential for retinal injury and at the high end to be a skin hazard as well.

Class 4 (IV) has no upper limit. Class 4 lasers are considered to be hazardous not only by direct exposure but also by exposure to laser radiation scattered by diffuse targets.

Since the laser hazard classes are already in place, the ignition potential of the classes can be considered. The potential for ignition involves many factors, including the following:

(1) Power or energy
(2) Irradiance or radiant exposure
(3) Size of the laser spot on the target
(4) Duration of exposure
(5) Environmental factors such as the presence of fabric drapes, volatile solvents, or oxygen-enriched atmospheres (OEAs) in health care facilities
(6) Thickness of the target material
(7) Thermal conductivity of the target material

A general assessment of the ignition potential for the classes is given in Table D.1.

Table D.1 Laser Ignition Potential

Classification	Examples	Ignition Potential	Remarks
1, 2 (I, II)	CD players, laser printers, fiber-optic telecommunications, bar code scanners	Negligible	Not considered in NFPA 115
1M, 2M	Distance-measuring instruments, police radar, infrared telecom	Conceivable but improbable	Unlikely that one would position a lens in front of such a laser and focus it to cause ignition; not considered in NFPA 115
3a (IIIa), 3R	Laser pointers, laboratory lasers	Possible under extreme circumstances	Necessitates a deliberate attempt to cause ignition; not considered in NFPA 115
3b (IIIb), 3B	Industrial machine vision, laboratory lasers, medical lasers (e.g., for tattoo removal)	Possible at the high end of the class	Focusing optics or an irradiance >0.5 W/cm^2; requirements in NFPA 115
4 (IV)	Surgical lasers, industrial lasers, commercial light shows, laboratory lasers	Probable for highly absorbent materials	Requirements in NFPA 115

Annex E Flash Point

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

E.1 The following text is extracted from the 2015 edition of NFPA 30.

Flash point is a direct measure of a liquid's ability to emit flammable vapors. The lower the flash point, the greater the risk of fire. Flash point is determined using one of several different test procedures and apparatus that are specified in Section 4.4 of NFPA 30.

A liquid that has a flash point at or below ambient temperature is easy to ignite and will burn quickly. On ignition, the spread of flame over the surface of such a liquid will be rapid, because it is not necessary for the fire to expend energy heating the liquid to generate more vapor. Gasoline is a familiar example. A liquid with a flash point above ambient temperature presents less risk because it must be heated to generate enough vapor to become ignitible; it is more difficult to ignite and presents less potential for the generation and spread of vapor. A common example is home heating oil (Fuel Oil No. 2). Home heating oil must be atomized to a fine mist in order for it to be easily ignited.

Certain solutions of liquids in water exhibit a flash point using the standard closed-cup test procedures but will not burn and could even extinguish a fire. To assist identifying such solutions, the following standards are helpful:

(1) ASTM D4207, *Standard Test Method for Sustained Burning of Low Viscosity Liquid Mixtures by the Wick Test*
(2) ASTM D4206, *Standard Test Method for Sustained Burning of Liquid Mixtures Using the Small Scale Open-Cup Apparatus*

Liquid mixtures that do not sustain combustion for a specified time at a specified temperature are considered to be noncombustible. The tests described in the references listed in (1) and (2) provide additional data for determining proper storage and handling of such mixtures. In a confined space, such mixtures could still create an ignitible vapor–air mixture, depending on the amount of flammable liquid in the mixture and the quantity of the spill.

Related to the flash point is the *fire point*. The fire point of a liquid is the temperature at which ignition of vapors will result in continued burning. As the term *flash point* suggests, the vapors generated at that temperature will flash but will not necessarily continue to burn. The difference between flash point and fire point has some significance when conducting flash point tests *[see 9.1.4 of NFPA 30 for references to ASTM D92, Standard Test Method for Flash and Fire Points by Cleveland Open Cup, and 49 CFR (U.S. Department of Transportation Hazardous Materials Regulations), Method of Testing for Sustained Combustibility]. However, a closed-cup flash point is used to classify the liquid and characterize its hazard.*

For more information, see ASTM E502, *Standard Test Method for Selection and Use of ASTM Standards for the Determination of Flash Point of Chemicals by Closed Cup Methods*, and the *ASTM Manual on Flash Point Standards and Their Use*.

NFPA® 120

Standard for

Fire Prevention and Control in Coal Mines

2015 Edition

This edition of NFPA 120, *Standard for Fire Prevention and Control in Coal Mines*, was prepared by the Technical Committee on Mining Facilities. It was issued by the Standards Council on November 11, 2014, with an effective date of December 1, 2014, and supersedes all previous editions.

This edition of NFPA 120 was approved as an American National Standard on December 1, 2014.

Origin and Development of NFPA 120

In 1977, with the formation of the Mining Committee, this standard, NFPA 120, formerly NFPA 653, was reassigned to the Committee on Mining Facilities. The change in numerical identity of the standard was in keeping with the numbering sequence assigned to the Mining Committee for other documents now under development. NFPA 120 represents a complete revision of former NFPA 653 and also includes changes in style in accordance with the NFPA *Manual of Style*.

The 1971 edition of NFPA 653, *Coal Preparation Plants*, was the same as the 1959 edition and was adopted at the NFPA 1971 Annual Meeting. The 1959 edition of NFPA 653 was prepared by the NFPA Committee on Dust Explosion Hazards and was adopted at the 1958 Annual Meeting with an amendment adopted in 1959.

The 1994 edition of NFPA 120 included a variety of technical and editorial updates. Previous editions not already mentioned include versions issued in 1984 and 1988.

The 1999 edition addressed the need for emergency lighting, expanded the types of portable fire extinguishers used, and expanded and clarified the types of fire suppression equipment used. The water supply requirements also were clarified.

The 2004 edition applied the NFPA *Manual of Style* to the document. It also incorporated all the appropriate sections of NFPA 121 and NFPA 123, which was done in an effort to consolidate common requirements.

The Coal Mining Task Group for the 2004 edition consisted of the following members: Matt Bujewski, Chair, Marsh Inc.; Tim Gierer, Alltype Fire Protection; Dennis Brohmer, Ansul Inc.; Jay Senn, Peabody Energy Group; Charlie Russell, Arch Coal Inc.; Brent Sullivan, Coteau Properties; Carol Boring, Mine Safety and Health Administration; Alex Smith, NIOSH; Mario Orozco, Zurich Services Corp.; Mike Wegleitner, Falkirk Mining Co. (alternate for Brent Sullivan); and Bill Wilson, U.S. Department of Labor (alternate for Carol Boring).

For the 2010 edition, the technical committee has revised the fire prevention and fire protection provisions for coal mines by requiring the use of means to manage the spontaneous combustion potential of the coal being mined, including adding an inspection plan for carbon monoxide detection systems. The fire prevention practices for coal mines have been improved by referencing the inspection and maintenance practices of fire suppression systems in the corresponding NFPA fire suppression standard. The Committee has provided improved fire protection for transformers by referencing *NFPA 70, National Electrical Code*, and adding NFPA 850, *Recommended Practice for Fire Protection for Electric Generating Plants and High Voltage Direct Current Converter Stations*, as an annex reference. Similarly, the standard has been revised to make it consistent with fire protection industry practices and the updated provisions in NFPA 122, *Standard for Fire Prevention and Control in Metal/Nonmetal Mining and Metal Mineral Processing Facilities*.

For the 2014 edition, the technical committee rewrote the sprinkler requirements in a more coherent manner and provided additional guidance for underground sprinkler systems. The committee established a common definition and a protection scheme for self-propelled, mobile, and portable equipment.

This list represents the membership at the time the Committee was balloted on the final text of this edition. Since that time, changes in the membership may have occurred. A key to classifications is found at the back of the document.

NOTE: Membership on a committee shall not in and of itself constitute an endorsement of the Association or any document developed by the committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on safeguarding life and property against fire, explosion, and related hazards associated with underground and surface coal and metal and nonmetal mining facilities and equipment.

NFPA 120

Standard for

Fire Prevention and Control in Coal Mines

2015 Edition

IMPORTANT NOTE: This NFPA document is made available for use subject to important notices and legal disclaimers. These notices and disclaimers appear in all publications containing this document and may be found under the heading "Important Notices and Disclaimers Concerning NFPA Standards." They can also be obtained on request from NFPA or viewed at www.nfpa.org/disclaimers.

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates that explanatory material on the paragraph can be found in Annex A.

A reference in brackets [ ] following a section or paragraph indicates material that has been extracted from another NFPA document. As an aid to the user, the complete title and edition of the source documents for extracts in mandatory sections of the document are given in Chapter 2 and those for extracts in informational sections are given in Annex B. Extracted text may be edited for consistency and style and may include the revision of internal paragraph references and other references as appropriate. Requests for interpretations or revisions of extracted text shall be sent to the technical committee responsible for the source document.

Information on referenced publications can be found in Chapter 2 and Annex B.

Chapter 1 Administration

1.1 Scope.

1.1.1* This standard shall cover minimum requirements for reducing loss of life and property from fire and explosion in the following:

(1) Underground bituminous coal mines
(2) Coal preparation plants designed to prepare coal for shipment
(3) Surface building and facilities associated with coal mining and preparation
(4) Surface coal and lignite mines

1.1.2 This standard shall not apply to the following:

(1) Flammable and combustible liquids produced in underground coal mines
(2) Other equipment and processes, such as coal pulverizers, used to condition coal for firing in boilers at power-generating plants or gasification plants or for utilization in certain special processes

1.2 Purpose. This standard shall be intended for the use and guidance of those charged with designing, constructing, purchasing, testing, installing, examining, approving, operating, or maintaining fire prevention, fire protection, or fire-fighting equipment in underground bituminous coal mines, coal preparation plants, and surface mining equipment and processes.

1.3* Application.

1.3.1 This standard shall be based on the current state of the art, and application to existing installations shall not be mandatory. Nevertheless, operating mines are urged to adopt those features of this standard that are considered applicable and reasonable for existing installations.

1.3.2 At times it will be necessary for those responsible for the storage of flammable and combustible liquids and the use of diesel-powered equipment within underground bituminous coal mines to consult an experienced fire protection specialist, and it shall be permitted.

1.3.3 Only those skilled in fire protection shall be considered competent to design and supervise the installation of mine fire protection systems.

1.3.4 Coal preparation plants shall be designed by experienced persons familiar with fire and explosion hazards in coal-processing plants.

1.3.5 At times it will be necessary for those charged with purchasing, testing, approving, and maintaining fire protection equipment for self-propelled and surface mining equipment to consult an experienced fire protection specialist.

1.4 Retroactivity. The provisions of this standard reflect a consensus of what is necessary to provide an acceptable degree of protection from the hazards addressed in this standard at the time the standard was issued.

1.4.1 Unless otherwise specified, the provisions of this standard shall not apply to facilities, equipment, structures, or installations that existed or were approved for construction or installation prior to the effective date of the standard. Where specified, the provisions of this standard shall be retroactive.

1.4.2 In those cases where the authority having jurisdiction determines that the existing situation presents an unacceptable degree of risk, the authority having jurisdiction shall be permitted to apply retroactively any portions of this standard deemed appropriate.

1.4.3 The retroactive requirements of this standard shall be permitted to be modified if their application clearly would be impractical in the judgment of the authority having jurisdiction, and only where it is clearly evident that a reasonable degree of safety is provided.

1.4.4 Operators are urged to avail themselves of any information that will prevent dust dispersions, eliminate sources of ignition, or otherwise reduce fire and explosion hazards by improving conditions in their plants.

1.5 Equivalency. Nothing in this standard is intended to prevent the use of systems, methods, or devices of equivalent or superior quality, strength, fire resistance, effectiveness, durability, and safety over those prescribed by this standard.

1.5.1 Technical documentation shall be submitted to the authority having jurisdiction to demonstrate equivalency.

1.5.2 The system, method, or device shall be approved for the intended purpose by the authority having jurisdiction.

Chapter 3 Definitions

3.1 General. The definitions contained in this chapter shall apply to the terms used in this standard. Where terms are not defined in this chapter or within another chapter, they shall be defined using their ordinarily accepted meanings within the context in which they are used. *Merriam-Webster's Collegiate Dictionary,* 11th edition, shall be the source for the ordinarily accepted meaning.

3.2 NFPA Official Definitions.

3.2.1* Approved. Acceptable to the authority having jurisdiction.

3.2.2* Authority Having Jurisdiction (AHJ). An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

3.2.3 Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

3.2.4* Listed. Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

3.2.5 Shall. Indicates a mandatory requirement.

3.2.6 Should. Indicates a recommendation or that which is advised but not required.

3.2.7 Standard. An NFPA Standard, the main text of which contains only mandatory provisions using the word "shall" to indicate requirements and that is in a form generally suitable for mandatory reference by another standard or code or for adoption into law. Nonmandatory provisions are not to be considered a part of the requirements of a standard and shall be located in an appendix, annex, footnote, informational note, or other means as permitted in the NFPA Manuals of Style. When used in a generic sense, such as in the phrase "standards development process" or "standards development activities," the term "standards" includes all NFPA Standards, including Codes, Standards, Recommended Practices, and Guides.

3.3 General Definitions.

3.3.1 Adequate Ventilation. Air volume and velocity that is sufficient to dilute, render harmless, and carry away flammable or explosive concentrations of dusts and vapors.

3.3.2 Atmospheric Tank. A storage tank that has been designed to operate at pressures from 760 mm Hg through 812 mm Hg (atmospheric through 1.0 psig) measured at the top of the tank.

3.3.3 Boiling Point. The temperature at which the vapor pressure of a liquid equals the surrounding atmospheric pressure. [**30,** 2015]

3.3.4 Closed Container. A container as herein defined, so sealed by means of a lid or other device that neither liquid nor vapor will escape from it at ordinary temperatures. [**30,** 2015]

3.3.5 Coal Preparation. The separation, crushing, screening, washing, drying, storage, and loadout of coal to make ready for market.

3.3.6 Combustible. Capable of undergoing combustion.

3.3.7 Combustible Liquid. Any liquid that has a closed-cup flash point at or above 37.8°C (100°F), as determined by the test procedures and apparatus set forth in Section 4.4 of NFPA 30. Combustible liquids are classified according to Section 4.3 of NFPA 30. [**30,** 2015]

3.3.8 Combustible Liquid Storage Area — Fixed. An area used for storage of Class II and Class III combustible liquids that is infrequently moved, and where the aggregate quantity present shall not exceed 18,925 L (5000 gal). Handling of liquids incidental to transfer can take place within a storage area.

3.3.9 Combustible Liquid Storage Area — Mobile. Self-propelled or mobile equipment fitted with suitable containers or tanks and other related fixtures used for the storage, transport, and dispensing of Class II and Class III combustible liquids. The aggregate quantity of combustible liquid carried on such equipment does not exceed 3785 L (1000 gal).

3.3.10 Combustible Liquid Storage Area — Portable. An area used for storage of Class II and Class III combustible liquids that is periodically moved, and where the aggregate quantity present does not exceed 3785 L (1000 gal). Handling of liquids incidental to transfer can take place within a storage area.

3.3.11 Combustion. A chemical process of oxidation that occurs at a rate fast enough to produce heat and usually light in the form of either a glow or flame. [**5000,** 2015]

3.3.12 Container. Any vessel of 450 L (119 gal) or less capacity used for transporting or storing liquids. [**30,** 2015]

3.3.13 Diesel-Powered Equipment. Any device powered by a diesel engine. [**122,** 2015]

3.3.14 Dry Pipe Sprinkler System. A sprinkler system employing automatic sprinklers that are attached to a piping system containing air or nitrogen under pressure, the release of which (as from the opening of a sprinkler) permits the water pressure to open a valve known as a dry pipe valve, and the water then flows into the piping system and out the opened sprinklers. [**13,** 2013]

3.3.15 Emergency Egress. An egress from a compartment or work station in emergencies when the normal egress is unusable.

3.3.16 Equipment Operator. The authorized person who starts, controls, or stops mining equipment.

3.3.17 Fire Detector. An automatic device designed to detect the presence of fire and initiate action. [**122,** 2015]

3.3.18 Fire-Resistant Construction. Masonry walls or equivalent having at least a 1-hour fire rating, including compressible materials having an equivalent fire resistance capability.

3.3.19 Fire-Resistant Enclosure. An enclosure that is constructed of fire-resistant construction.

3.3.20 Fire Risk Assessment. The evaluation of the relative danger of the start and spread of fire; the generation of smoke, gases, or toxic fumes; and the possibility of explosion or other occurrence endangering the lives and safety of personnel or causing significant damage to property. [**122,** 2015]

3.3.21 Fixed Fire Suppression System. An engineered or pre-engineered total flooding or local application system consisting of a fixed supply of extinguishing agent permanently connected for fixed agent distribution to fixed nozzles that are arranged to discharge an extinguishing agent into an enclosure (total flooding), directly onto a hazard (local application), or a combination of both; or an automatic sprinkler system. [**122,** 2015]

3.3.21.1 ***Engineered Systems.*** Engineered systems are those systems requiring individual calculation and design to determine the flow rates, nozzle pressures, pipe size, area, or volume protected by each nozzle, quantity of suppression agent, number and types of nozzles and their placement in a specific system.

3.3.21.2 ***Pre-Engineered Systems.*** Those systems having predetermined flow rates, nozzle pressures, and quantities of extinguishing agent and having specific pipe size, maximum and minimum pipe lengths, flexible-hose specifications, number of fittings, and number and types of nozzles. [**17,** 2013]

3.3.22 Flammable Liquid. Any liquid that has a closed-cup flash point that is below 37.8°C (100°F), as determined by the test procedures and apparatus set forth in Section 4.4 of NFPA 30 and a Reid vapor pressure that does not exceed an absolute pressure of 276 kPa (40 psi) at 37.8°C (100°F), as determined by ASTM D323, *Standard Test Method for Vapor Pressure of Petroleum Products (Reid Method)*. Flammable liquids are classified according to 4.3 of NFPA 30. [**30,** 2015]

3.3.23 Flammable Liquid Storage Area. Area used for storage of Class I liquids.

3.3.24 Flash Point. The minimum temperature of a liquid at which sufficient vapor is given off to form an ignitable mixture with the air, near the surface of the liquid or within the vessel used, as determined by the appropriate test procedure and apparatus specified in Section 4.4 of NFPA 30. [**30,** 2015]

3.3.25 Hand Hose Line System. A hose and nozzle assembly connected by fixed piping or connected directly to a supply of extinguishing agent. [**122,** 2015]

3.3.26 Hydrant. A valved hose connection.

3.3.27 Important Structures. A structure that is considered not expendable in an exposure fire.

3.3.28 Inby. A mining term that means in the direction of the face of the mine or further into the mine.

3.3.29 Intrinsically Safe. As applied to equipment and wiring, equipment and wiring that are incapable of releasing sufficient electrical energy under normal or abnormal conditions to cause ignition of a specific hazardous atmospheric mixture. [**99,** 2015]

3.3.30 Liquid. Any material that (1) has a fluidity greater than that of 300 penetration asphalt when tested in accordance with ASTM D5, *Standard Test Method for Penetration of Bituminous Materials*, or (2) is a viscous substance for which a specific melting point cannot be determined but that is determined to be a liquid in accordance ASTM D4359, *Standard Test for Determining Whether a Material is a Liquid or a Solid*. [**30,** 2015]

3.3.31 Low Pressure Tank. A storage tank designed to withstand an internal pressure above 3.5 kPa (0.5 psig) but not more than 102.4 kPa (15 psig).

3.3.32 Mine Operator. Any owner, lessee, or other person who operates, controls, or supervises a mine. [**122,** 2015]

3.3.33* Mobile Equipment. Wheeled, skid-mounted, track-mounted, or rail-mounted equipment capable of moving or being moved.

3.3.34 Noncombustible. Not capable of supporting combustion.

3.3.35 Normal Operation. The regular performance of those functions for which a machine or accessory is designed.

3.3.36 Operating Area. An area where mining of coal is taking place or area where construction is underway.

3.3.37 Outby. A mining term that means in the direction away from the face of the mine or toward the outside of the mine; opposite of inby.

3.3.38 Permissible Equipment. A completely assembled machine or accessory for which formal approval has been issued, allowing operation in a potentially explosive methane and air-mixture environment.

3.3.39 Pipeline System. An arrangement of piping, valves, connections, and allied equipment installed in a mine for the purpose of transporting, transferring, or dispensing flammable or combustible liquids. [**122,** 2015]

3.3.40 Portable Extinguisher. An extinguisher of the hand-held or wheeled type that is capable of being carried or moved about, or a transportable system consisting of a hose reel or rack, hose, and discharge nozzle assembly connected to a supply of suppressant.

3.3.41 Portable Tank. Any vessel having a liquid capacity over 227 L (60 gal) intended for storing liquids and not intended for fixed installation. [**30,** 2015]

3.3.42 Pressure Vessel. A container or other component designed in accordance with the ASME *Boiler and Pressure Vessel Code* or the CSA B51, *Boiler Pressure Vessel and Pressure Piping Code*. [**52,** 2013]

3.3.43 Rock Dust. Crushed limestone applied on surfaces in mines to make coal dust incombustible in the event of a gas explosion.

3.3.44 Safety Can. A listed container, of not more than 20 L (5.3 gal) capacity having a screen or strainer in each fill and pour opening and having a spring-closing lid and spout cover designed to safely relieve internal pressure when exposed to fire. [**30,** 2015]

3.3.45 Self-Closing Doors. Doors that, when opened and released, return to the closed position. [**80,** 2013]

3.3.46 Self-Propelled Equipment. Any unit that contains a motive power train as an integral part of the unit.

3.3.47 Suitable. That which is appropriate and has the qualities or qualifications to meet a given purpose, occasion, condition, function, or circumstance. [**122,** 2015]

3.3.48 Tank. A closed vessel having a liquid capacity in excess of 227 L (60 gal). [**122,** 2015]

3.3.49 Task Trained. Instructed in the safety and health aspects and safe work procedures of the task prior to performing such tasks.

3.3.50 Unattended. Any machine or device that is not regularly operated by a miner or not in direct line of sight of a miner that is assigned within 152.4 m (500 ft) of the equipment during each production shift.

Chapter 4 Underground Mining Operations

4.1 General. This chapter shall cover minimum requirements for reducing loss of life and property from fire in underground coal mines.

4.2* Fire Prevention. Precautions shall be taken to prevent the ignition of flammable vapors and combustible materials.

4.2.1 Smoking materials, matches, and lighters shall not be allowed underground.

4.2.2 Rock Dusting. Rock dust shall be provided on the ribs, ceiling, and floor of the mine from the mine entry to the working face in all areas of the mine that are active (not sealed).

4.2.2.1 Rock dust shall be maintained at a concentration of 80 percent.

4.2.3 Cutting and Welding. Cutting and welding and compressed gas usage shall be in accordance with Section 7.1.

4.2.4 Housekeeping.

4.2.4.1 Maintenance and operating practices shall prevent the accidental release of flammable or combustible liquids.

4.2.4.2 A cleanup plan shall be established, implemented, and monitored to prevent the accumulation of loose coal and other combustible materials.

4.2.4.3 Where flammable or combustible liquids are used or handled, means shall be provided to dispose of leakage or spills.

4.2.4.4 Waste receptacles shall be provided for combustible refuse.

4.2.4.5 Routes designated for access to fire protection equipment shall be kept clear of obstructions.

4.2.5 Underground Maintenance Shops.

4.2.5.1* Underground maintenance shops that are intended for use longer than 6 months shall be enclosed structures of fire-resistant construction, including floor, roof, roof supports, doors, and door frames, or shall be protected with an automatic sprinkler fire suppression system in accordance with 4.3.3.3.

4.2.5.2 The shop area shall be ventilated directly to a return airway.

4.2.6* Belt Conveyors. Belt conveyors installed in underground coal mines shall, as a minimum, meet all the requirements of Section 9.4 of this standard.

4.2.7 Hydraulic Fluids.

4.2.7.1 Fire-resistant hydraulic fluid shall be approved by the authority having jurisdiction.

4.2.7.2 Unattended hydraulic equipment shall employ fire-resistant hydraulic fluid and be protected by an automatic fire suppression system.

4.2.7.3 Where fire-resistant fluids are required, samples of in-use fire-resistant fluids of the invert emulsion type shall be collected quarterly.

4.2.7.3.1 Samples of the in-use fire-resistant fluids shall be tested individually to determine if the water content will make the fluid fire resistant.

4.2.7.3.2 When a sample of the in-use fire-resistant fluids indicates that the water content is insufficient for the fluid to be fire resistant, the fluid shall be replaced or water shall be added to restore the fire resistance of the fluid.

4.2.7.3.3 When water is added to the hydraulic system of any machine, a sample shall be taken and analyzed within 24 hours.

4.2.8 Flammable Liquids Storage and Use. The storage and use of flammable liquids underground shall conform to Section 7.5.

4.2.9 Combustible Liquids Storage and Use. The storage and use of combustible liquids underground shall conform to Section 7.6.

4.2.10 Methane Control. Methane within the coal mine shall be reduced to not more than 1 percent on the intake air and 2 percent on the return air.

4.2.10.1 Methane monitors shall be provided on equipment used to cut coal from the face.

4.2.10.1.1 The methane monitors shall alarm at 1 percent concentration and be interlocked to shut down the machine at a 2 percent concentration of methane.

4.2.11* Spontaneous Combustion.

4.2.11.1 Mine operators shall determine the spontaneous combustion potential of the coal being mined.

4.2.11.2* Mines with a high spontaneous combustion potential shall take means to minimize the spontaneous combustion risk.

4.3* Fire Protection.

4.3.1 Water Supply for Mine Fire Protection.

4.3.1.1 General Requirements.

4.3.1.1.1* Water distribution lines shall extend from the surface to each operating area.

4.3.1.1.2 Water distribution lines from a suitable underground supply of water shall be permitted to replace the surface distribution lines if sufficient quantity is available and power for the pump(s) will not be affected or interrupted during a fire.

4.3.1.1.3 The operator shall choose the entry in which the water line is located, and it shall be protected by the choice of location.

4.3.1.1.4 Water flow and ventilation airflow shall be in the same direction unless provision is made to ensure the availability of fire-fighting water on the upwind side of a fire in the entry containing the water line.

4.3.1.1.5 Where applicable, water lines shall be protected against freezing.

4.3.1.1.6 Water lines that are 50 mm (2 in.) or larger in diameter shall be joined with flanges, mechanical grooved fittings, threaded fittings, or other fittings.

4.3.1.1.7 At least every third joint shall be capable of allowing limited motion and emergency rearrangement.

4.3.1.1.8 Pipe and fittings shall be of metal construction and designed to withstand the anticipated water pressure.

4.3.1.1.9* Water lines shall be equipped with shutoff valves at intervals not exceeding 1524 m (5000 ft).

4.3.1.1.10 A shutoff valve shall be provided in each branch line at the point where it is coupled to the main water line.

4.3.1.1.10.1 Shutoff valves for fire protection shall be sealed, locked, or supervised in the open position.

4.3.1.2 Water Demand.

4.3.1.2.1* All coal mine water systems shall be capable of simultaneously supplying three hose streams, each with a flow rate of at least 190 L/min (50 gpm), and a nozzle pressure of at least a gauge pressure of 345 kPa (50 psi) for a total of 570 L/min (150 gpm), applied through the maximum expected lay of hose.

4.3.1.2.2* The mine water system shall be capable of supplying the required hose stream water demand continuously for 24 hours or the sprinkler water demand continuously for 2 hours, whichever is the greater supply.

4.3.1.3 Hydrants.

4.3.1.3.1* The mine operator shall choose the entry in which hydrants are to be located, except for belt conveyor entries where hydrants shall be located in the same entry as the belt, locate personnel doors, and provide fire hose that reaches parallel entries where risk of fires exists.

4.3.1.3.2* Hydrants that supply water to a fire hose shall be provided on the water line at intervals not exceeding 91.4 m (300 ft) for belt conveyors and 152.4 m (500 ft) for haulage tracks.

4.3.1.3.3 Hydrants shall be located in the belt entry and accessible.

4.3.1.3.3.1 If staggered crosscuts are used, hydrant locations and crosscuts with personnel doors shall be located to provide a route for laying a fire hose to parallel entries.

4.3.1.3.3.2 At least one hydrant shall be located upwind of the area protected by an automatic sprinkler system.

4.3.1.4 Maintenance. The water supply system shall be maintained operable.

4.3.2* Protective Signaling Fire Detection Systems.

4.3.2.1 General Requirements.

4.3.2.1.1* The design and installation of all fire detection systems shall be approved for the intended use.

4.3.2.1.2 Fire detectors and related signaling system components used to initiate an audible or visual alarm, automatic activation of a fire suppression system, or equipment shutdown shall be listed or approved for the intended use.

4.3.2.1.3* Signaling system input, alarm, and releasing circuits shall be supervised.

4.3.2.1.3.1 The presence of a fault, alarm, or release shall initiate a signal in the protected area and remotely in a constantly attended location.

4.3.2.1.3.2 The signal specified in 4.3.2.1.3.1 shall indicate which condition has occurred.

4.3.2.1.3.3 A trouble signal shall not be required when the main power supply is intentionally shut off during periods of mine inactivity.

4.3.2.1.4* All components of protective signaling systems used inby the last open crosscut or in return air shall be classified as permissible or intrinsically safe.

4.3.2.2 Selection and Application.

4.3.2.2.1* Carbon monoxide (CO) detectors or the equivalent shall be installed along all belt conveyors and at all unattended automatic belt heads (where mine cars are loaded automatically).

4.3.2.2.2* Compartment sizes and contours, airflow patterns, obstructions, and other characteristics of the protected area shall determine the placement, type, sensitivity, and, where applicable, number of detectors.

4.3.2.2.3 The fire alarm shall identify a fire within each belt flight (segment).

4.3.2.2.4 Fire detection systems shall be installed so as to minimize the possibility of damage from roof falls and from the moving belt and its load.

4.3.2.2.5 The voltage of automatic fire alarm systems shall not exceed 120 volts.

4.3.2.2.6 The system shall be designed to provide an alarm up to 4 hours after the source of power to the belt is shut off.

4.3.2.2.7 An audible and visual alarm shall be provided either at the location of the belt or at a constantly attended location that has a telephone or equivalent communication with those miners who might be endangered.

4.3.2.2.8 The alarm system shall be equipped with a "trouble" signal to indicate open circuits, shorts, ground faults, or any other defects.

4.3.2.2.9 The alarm system shall include a manual reset feature.

4.3.2.3 Inspection, Maintenance, and Testing.

4.3.2.3.1 Fire detection systems and associated equipment shall be tested after installation according to the manufacturer's or designer's instruction manual.

4.3.2.3.2 The detection system shall be inspected visually weekly.

4.3.2.3.3 Carbon monoxide detection systems shall be visually inspected daily, functionally tested weekly, and calibrated monthly, not to exceed 31 days between calibrations.

4.3.3 Fire Protection Systems.

4.3.3.1 General Requirements.

4.3.3.1.1 Mining equipment requiring a fixed fire protection system shall be protected by a system with the capacity to suppress the largest anticipated fires in the protected areas and shall meet the following criteria:

(1) They shall be listed or approved for the purpose.
(2) They shall be located or guarded so as to be protected against physical damage.
(3)*They shall be actuated either automatically, manually, or both.
(4)*They shall be provided with an agent distribution hose or pipe secured and protected against damage, including abrasion and corrosion, and shall be flame resistant.
(5) They shall be provided with discharge nozzle blowoff caps or other devices or materials to prevent the entrance of moisture, dirt, or other material into the piping. The discharge nozzle protective device shall blow off, blow out, or open upon agent discharge.
(6)*Water-based systems shall not be required to have nozzle blowoff caps as long as the nozzles are kept free of blockage at all times.
(7) The fire protection system shall be installed so that system actuation causes shutdown of the protected equipment.
(8) Discharge nozzles or sprinklers shall not be covered with any material that will reduce the effectiveness of the system.

4.3.3.1.2 Automatically actuated systems other than water-based sprinkler systems shall have a manual actuator capable of being activated from the operator's compartment or other accessible location.

4.3.3.1.3 Unless otherwise noted in this standard, fire protection systems shall be installed and operate in accordance with the applicable NFPA standard.

4.3.3.1.3.1 Pre-engineered systems shall be designed, installed, and tested in accordance with the fire suppression system manufacturer's listed installation and maintenance manual.

4.3.3.1.4* Where the nature of a coal mine does not allow the NFPA standards to be followed, systems that provide equivalent protection shall be approved by the authority having jurisdiction.

4.3.3.2 Applications.

4.3.3.2.1* The following equipment and facilities shall be protected by approved automatic fire protection systems. Where sprinkler systems are used, they shall satisfy the requirements of 4.3.3.3 through 4.3.3.5.4. Where dry chemical systems are used, they shall satisfy the requirements for self-propelled equipment in 4.3.3.6.1.

(1)*Drive areas of belt conveyors shall be protected in accordance with 9.4.6.
(2) Flammable and combustible liquid storage areas shall be protected by either one of the following:
   (a) Automatic water-based fixed fire protection systems installed for the protection of Class I or Class II liquid storage areas shall be of the Class B foam–water type.
   (b) Fixed diesel or other Class II combustible liquid storage areas shall be protected with a dry chemical system or a system that provides equivalent protection according to the authority having jurisdiction.
(3) Unattended hydraulic equipment shall use fire-resistant hydraulic fluid.
(4) Unattended electrical equipment such as enclosed electric motors, controls, transformers, rectifiers, battery chargers, and other equipment that does not have a hydraulic system shall be protected by an approved automatic fire protection system.
(5) Unattended electrical equipment located on noncombustible material and spaced at least 0.61 m (2 ft) from coal or other combustible material shall not be required to be protected with an automatic fire suppression system.
(6) Unattended electrical equipment located on noncombustible material and separated from coal or other combustible material by a fire-resistive layer or wall shall not be required to be protected with an automatic fire suppression system.

4.3.3.2.2* Air Compressors. Air compressors with motors that exceed 5 horsepower shall be protected by an approved automatic fire protection system interlocked to shut down the power to the compressor and by one of the following:

(1) A person in constant attendance, within the line of sight of the compressor, and equipped with a portable fire extinguisher
(2) Containment within an enclosure that is constructed of noncombustible materials, ventilated to prevent overheating of the compressor, and designed to provide containment of any possible fire involving the compressor

4.3.3.3 Sprinkler System Requirements.

4.3.3.3.1* Water Supply. The water supply shall have enough pressure and flow to provide sprinkler coverage as the sprinkler design is intended.

4.3.3.3.1.1 An approved strainer with a flush-out connection and a manual shutoff valve shall be provided at the point of the sprinkler system connection to the main water line.

4.3.3.3.1.2 An indicating, full-flow, slow-opening water control valve shall be located at the tap of the water line supplying the sprinkler system.

4.3.3.3.1.3 When the sprinkler system is put into operation, the slow-opening valve specified in 4.3.3.3.1.2 shall be sealed or locked in the open position, or be provided with a supervisory alarm.

4.3.3.3.1.4 A pressure gauge shall be provided at the point of connection.

4.3.3.3.1.5 The water line from the water main to the sprinkler system shall be metallic.

4.3.3.3.1.6 The water line from the water main to the sprinkler system of a belt drive shall be flexible metal or reinforced nonmetal if excessive vibration could reduce the reliability of the sprinkler system.

4.3.3.3.1.7 Fittings and piping shall have a rated pressure higher than the anticipated maximum pressure on the system.

4.3.3.3.2 General Installation Requirements.

4.3.3.3.2.1* Piping in sprinkler systems shall comply with NFPA 13.

4.3.3.3.2.2 Nonmetallic pipe shall not be used downstream of the sprinkler control valve unless investigated and approved for this purpose.

4.3.3.3.2.3 Hangers supporting sprinkler piping shall be metallic.

4.3.3.3.2.4 At least one hanger shall be attached to each length of pipe.

4.3.3.3.2.5* Sprinklers shall be standard orifice pendent, upright, or sidewall-type automatic sprinklers.

4.3.3.3.2.6* For sprinkler systems installed to protect the equipment and facilities indicated in 4.3.3.2.1(2) through 4.3.3.2.1(6), sprinklers shall be spaced no more than 3.66 m (12 ft) apart, and the protection of any one sprinkler shall not exceed 9.3 m^2 (100 ft^2).

4.3.3.3.2.7* Sprinklers shall be located so that the discharge will not be obstructed.

4.3.3.3.2.8 Sprinkler deflectors shall be located at a distance below the roof of not less than 25.4 mm (1 in.) nor greater than 508 mm (20 in.).

4.3.3.3.2.9 Roof cavities containing combustible material such as wood or coal in the area to be protected shall be protected by installation of upright sprinklers within the cavity at the top of riser pipes so that the deflectors are within 508 mm (20 in.) of the roof.

4.3.3.3.2.10 Wet-pipe sprinkler systems shall not be used where chance of freezing exists.

4.3.3.3.2.11 Provisions shall be made to drain all parts of the system.

4.3.3.3.2.12 Drain connections shall be sized as shown in Table 4.3.3.3.2.12.

4.3.3.3.2.13 Trapped piping sections shall be equipped with auxiliary drains or otherwise arranged to facilitate draining.

Table 4.3.3.3.2.12 Sizes of Drain Connections

Riser or Main Size	Size of Drain Connection
Up to 2 in.	¾ in. or larger
2½ in. to 3½ in.	1¼ in. or larger
4 in. and larger	2 in. only

For SI units, 1 in. = 25.4 mm.

4.3.3.3.3 General Alarm Requirements for Sprinkler Systems.

4.3.3.3.3.1 A waterflow switch or alarm valve capable of detecting the flow through one opened sprinkler shall be installed in the piping feeding the sprinklers.

(A) An inspector's test connection shall be provided at the end of the most remote line of the sprinkler system.

(B) The inspector's test connection shall simulate one sprinkler head in operation for sprinkler systems other than belt drive systems.

(C) In addition to 4.3.3.3.3.1(B), the inspector's test connection for belt drive systems shall simulate a minimum of eight sprinkler heads activating at the same time.

4.3.3.3.3.2 The alarm device shall be connected to an alarm system that will alarm at a constantly attended location. The alarm device shall provide a local audible and visual alarm.

4.3.3.3.3.3 The alarm system shall identify the sprinkler system involved.

4.3.3.3.3.4 In dry-pipe automatic sprinkler systems, the alarm system shall be actuated by a pressure switch associated with the trim on the dry-pipe device.

4.3.3.3.3.5 A paddle-type water flow switch shall be installed in wet systems only.

4.3.3.3.4 Antifreeze System. Where danger of freezing exists, sprinkler systems filled with antifreeze solution shall be permitted and shall meet the requirements of 7.6.2 and 7.6.3 of NFPA 13.

4.3.3.3.5* Dry-Pipe System. Where danger of freezing exists, a dry-pipe sprinkler system shall be permitted and shall meet the requirements of 4.3.3.3.5.1 through 4.3.3.3.5.7.

4.3.3.3.5.1 The dry-pipe valve and its accessories shall be installed in a separate area and shall be protected against freezing and mechanical injury.

4.3.3.3.5.2 If the separate area described in 4.3.3.3.5.1 is ventilated with return air, all electrical components shall be permissible or intrinsically safe.

4.3.3.3.5.3 Water pressure shall be regulated not to exceed the maximum pressure specified by the manufacturer of the dry-pipe valve.

4.3.3.3.5.4 The dry-pipe valve shall be installed in accordance with the manufacturer's instructions.

4.3.3.3.5.5 Mechanical grooved couplings, including gaskets used on dry-pipe systems, shall be listed for dry-pipe service.

4.3.3.3.5.6 Operation of the dry-pipe system and supervision of the system, including pressure of the air supply, shall be signaled to an attended location. Signaling to an attended location shall be permitted to utilize alarm systems serving fire detection equipment.

4.3.3.3.5.7 The system air supply shall be provided from a reliable source such as a dedicated compressor and shall be equipped with an air maintenance device.

4.3.3.3.5.8 Sprinklers shall be installed in the upright position on a dry-pipe system or be listed dry type or horizontal sidewall sprinklers installed according to the listing for dry-pipe systems.

4.3.3.3.6 Protection of Specific Hazards.

4.3.3.3.6.1* Automatic water-based fixed fire protection systems installed for the protection of Class I or Class II liquid storage areas shall be of the foam–water type.

4.3.3.3.6.2* Where the requirements of 9.4.6 dealing with underground belt drives are satisfied by installing automatic sprinkler systems, such systems shall comply with the requirements of 4.3.3.3.1.2 and 4.3.3.3.1.3.

4.3.3.4 Automatic Sprinkler System Acceptance Testing.

4.3.3.4.1 Flushing of Water-Line Connections.

4.3.3.4.1.1 Water-line connections and lead-in connections shall be flushed at the maximum flow rate available before connection is made to the sprinkler piping in order to remove foreign material.

4.3.3.4.1.2 Flushing shall be continued until the water is clear.

4.3.3.4.2 Flow Testing of Sprinkler Systems.

4.3.3.4.2.1 Wet-pipe closed automatic sprinkler systems shall be flow-tested by operating flow through at least one sprinkler head for non–belt drive areas and at least eight sprinkler heads for belt drive areas.

4.3.3.4.2.2 If the system contains fewer than eight sprinklers, all sprinklers or an inspector's test simulating all sprinklers shall be flow-tested as specified in 4.3.3.4.2.1.

4.3.3.4.2.3 With a water flow and pressure that is present under normal mine operating conditions, if the residual pressure measured downstream of the opened sprinklers is 70 kPa (10 psi) or greater for belt drive systems and 140 kPa (20 psi) for all other systems, the system shall be considered acceptable.

4.3.3.4.2.4 Closed sprinkler systems installed to protect areas where the water discharge could damage the area or its contents shall not be required to be tested by operating flow through opened sprinklers.

4.3.3.4.2.5 Where the condition(s) in 4.3.3.4.2.4 exist, the alternative test of operating flow through a 51 mm (2 in.) valve test connection shall be permitted to be used.

4.3.3.4.2.6 Portable sprinkler systems that are dismantled and reinstalled in new areas shall be flow-tested following the initial installation.

4.3.3.4.3 Tests of Dry-Pipe Sprinkler Systems.

4.3.3.4.3.1 Where there is no risk of freezing, new dry-pipe systems shall be flow-tested and hydrostatically tested in accordance with NFPA 13.

4.3.3.4.3.2 A dry-pipe valve shall be tested according to the manufacturer's recommendations.

4.3.3.4.3.3* Where there is risk of freezing in dry-pipe systems, an air pressure of 276 kPa (40 psi) shall be pumped up and allowed to stand 24 hours, and all leaks that allow a loss of pressure over 10.3 kPa (1½ psi) during the 24 hours shall be stopped.

4.3.3.5 Inspection, Maintenance, and Testing.

4.3.3.5.1 All fire suppression systems shall be tested after installation in accordance with the appropriate NFPA standard.

4.3.3.5.2 If an applicable NFPA standard does not exist, then a fire suppression system shall be tested in accordance with the manufacturer's or designer's instruction manual.

4.3.3.5.3 Testing shall not require the discharge of suppressant unless there is no other satisfactory manner in which the reliability and integrity of the system can be verified.

4.3.3.5.4* All persons who inspect, test, operate, or maintain fire suppression systems shall be trained.

4.3.3.5.5 Sprinkler System Maintenance.

4.3.3.5.5.1 All sprinkler systems shall be maintained in accordance with the manufacturer's requirements or in accordance with NFPA 25.

4.3.3.5.5.2* As a minimum, all closed-head sprinkler systems, except antifreeze systems, shall be flushed annually by operating flow through the end of the line drain(s) for the system to remove any silt buildup.

(A) If pendent sprinklers are used on wet-type sprinkler systems, the end sprinkler on each line shall be removed and examined annually to check for silt buildup.

(B) If silt buildup is found, all sprinklers on the line shall be removed, the line flushed, and new sprinklers installed.

4.3.3.5.5.3* As a minimum, deluge sprinklers and deluge water-spray systems shall be flow-tested on a monthly basis.

4.3.3.5.5.4 The strainer shall be flushed on a weekly basis, at a minimum.

4.3.3.5.6 Antifreeze Systems.

(A) Each year at the onset of freezing weather, a small amount of antifreeze shall be drawn from the drain valve and the test valve(s) and tested with a hydrometer to ensure that the solution is suitable for the lowest temperature expected.

(B) If the test described in 4.3.3.5.6(A) shows that the solution is not suitable, the solution shall be replaced.

4.3.3.6 Fire Suppression for Self-Propelled Equipment.

4.3.3.6.1* Fire suppression systems consisting of an agent container and a network of agent distribution hose or pipe with discharge nozzles attached shall be used to protect self-propelled equipment and shall comply with the following:

(1) The system shall suppress any potential fire on the equipment it is intended to protect.
(2) The fire suppression system shall be approved for the purpose, and the components shall be located or guarded to protect against damage.
(3) Fire suppression systems shall be actuated automatically, manually, or both.
(4) Automatically actuated systems designed to incorporate manual actuation shall be equipped with one or more such devices accessible for actuation and shall be maintained in operable condition.
(5) Discharge nozzles shall be provided with blow-off caps or other devices to prevent the entrance of moisture or other environmental materials into the piping.
(6) The protective device shall blow off, blow out, or open upon agent discharge.
(7) The electrical components of systems installed on equipment that might be operated in the last open crosscut or in return air shall be permissible.
(8) A standby source of power shall be provided if electrical power is the only means of actuation.
(9) All fire suppression equipment and systems shall be tested after installation in accordance with the manufacturer's or designer's recommendations.
(10) Testing shall not require the discharge of agent unless there is no other feasible way to evaluate the system.
(11)*An owner's or operations manual shall be provided for all fire suppression systems.
(12)*Fire suppression systems shall be inspected and maintained in accordance with the appropriate NFPA standard.

4.3.3.6.2* Fire suppression systems shall be provided for protection of attended, electrically powered, self-propelled equipment such as cutting machines, continuous miners, shearers, roof and coal drills, loaders, shuttle cars, scoops, and locomotives that use hydraulic fluid, unless fire-resistant hydraulic fluid is used.

4.3.3.6.3 Cutting machines, continuous miners, shearers, and other machines that supply water through a hose for dust control during mining shall be permitted to use this water source for fire protection, provided a diversion valve is at or out by the operator's station to permit quick and convenient diversion of water to the fire suppression nozzles.

4.3.4 Manual Fire Fighting.

4.3.4.1 Portable Fire Extinguishers.

4.3.4.1.1 General Requirements.

4.3.4.1.1.1* Portable fire extinguishers used in underground coal mines shall be listed, multipurpose (ABC) dry-chemical types having a minimum nominal capacity of 4.6 kg (10 lb) of extinguishing agent, and shall meet the requirements of NFPA 10.

4.3.4.1.1.2 Portable extinguishers shall be kept in their designated places.

4.3.4.1.1.3 Extinguishers shall be located where they will be accessible in the event of fire.

4.3.4.1.1.4 In areas where visual obstruction cannot be completely avoided, visible markings shall be provided to indicate the location.

4.3.4.1.1.5 Extinguishers subject to dislodgment shall be installed in brackets specifically designed for this problem.

4.3.4.1.1.6 Extinguishers shall be protected from physical damage.

4.3.4.1.1.7 Damaged extinguishers shall be repaired, replaced, or removed from service.

4.3.4.1.1.8 At least one hand-portable fire extinguisher having a nominal capacity of 9.1 kg (20 lb) with a minimum rating of 10-A:60-B:C shall be located outside of, but not more than 3.0 m (10 ft) from, the opening into each flammable and combustible storage area and maintenance shop.

4.3.4.1.1.9 The installation of manual or automatic fire suppression systems shall not waive the requirement of 4.3.4.1.1.8.

4.3.4.1.1.10 Where portable fire extinguishers are provided within flammable and combustible storage areas, travel distance to a portable extinguisher shall not exceed 12.2 m (40 ft).

4.3.4.1.2 Selection and Application.

4.3.4.1.2.1 Multipurpose (ABC) dry-chemical extinguishers shall be provided for protection of the following:

(1) Ventilation doors on trolley wire-supplied track haulageways
(2) Pumps and pump rooms
(3) Conveyor belt drives
(4) Belt head loading equipment
(5) Air compressors
(6) Electrical equipment such as transformers, load centers, rectifiers, circuit breakers, generators, and starters
(7) Rotary dump areas
(8) Battery-charging areas
(9) Intervals of 23 m (75 ft) along a longwall face unless washdown hose is present
(10) Flammable and combustible liquid storage areas
(11) Mobile equipment used for the storage, transport, and dispensing of combustible liquids
(12) Electric- or diesel-powered mobile equipment
(13) Self-propelled equipment

4.3.4.1.2.2 The installation of an automatic or manually operated fire suppression system shall not eliminate the requirement for a portable fire extinguisher.

4.3.4.1.2.3* At least one multipurpose (ABC) dry-chemical extinguisher having a nominal capacity of 13.6 kg (30 lb) or greater of agent or two multipurpose (ABC) dry-chemical extinguishers having a nominal capacity of 9.1 kg (20 lb) or greater of agent each shall be provided in each working section of a mine, including the headgate of a longwall face.

4.3.4.1.3 Inspection and Maintenance.

4.3.4.1.3.1 Portable fire extinguishers shall be inspected, maintained, and recharged as specified in NFPA 10, Chapter 7, and shall include the requirements of 4.3.4.1.3.2 through 4.3.4.1.3.9.

4.3.4.1.3.2* Visual Inspection.

(A) Portable fire extinguishers shall be inspected visually at least monthly.

(B) The visual inspection shall confirm the following:

(1) The extinguisher is in its designated place.
(2) The tamper seals are intact.
(3) The extinguisher gauge is in the operable range (if extinguisher is stored pressure type).
(4) There is no obvious physical damage or condition to prevent operation.

4.3.4.1.3.3 Extinguishers shall be subjected to a thorough maintenance examination at least once every 12 months.

4.3.4.1.3.4 Maintenance procedures shall include a thorough examination of the extinguisher, including mechanical parts, extinguishing agent, and the means of expulsion.

4.3.4.1.3.5 Any detected troubles or impairments shall be corrected or replaced immediately by competent personnel.

4.3.4.1.3.6 Each extinguisher shall have a durable tag or label securely attached on which the date of the maintenance services shall be recorded.

4.3.4.1.3.7 All extinguishers shall be recharged after any discharge.

4.3.4.1.3.8 All extinguishers shall be recharged as deemed necessary through inspection and maintenance.

4.3.4.1.3.9 Portable extinguishers shall be hydrostatically tested at intervals not exceeding those specified in NFPA 10, Chapter 8.

4.3.4.2 Hand Hose Line Systems.

4.3.4.2.1 Selection and Application.

4.3.4.2.1.1* Fire hose for use in underground coal mines shall be a minimum of 38 mm (1½ in.) in diameter, single or multiple jacket, and of a type suitable for coal mine use.

4.3.4.2.1.2 The hose shall meet the minimum applicable standards of NFPA 1961.

4.3.4.2.1.3 Hose lines employing natural fibers shall not be used in underground coal mines.

4.3.4.2.1.4* Fire hose, including couplings, shall be rated for the maximum line pressure that can exist on the mine water system, or there shall be provision for limiting the line pressure to the working pressure of the hose.

4.3.4.2.1.5 Nozzle flow pressure shall be adjusted to provide hose control.

4.3.4.2.1.6* Couplings for fire hose used in underground coal mines shall have straight, iron pipe threads or National Standard Thread.

4.3.4.2.1.7 Where hose or hose-connected equipment is brought in from outside the mine, compatible adapters shall be available.

4.3.4.2.1.8 Hose nozzles shall be capable of delivering a straight stream and a spray discharge.

4.3.4.2.1.9* Fire hose shall be stored in caches, and caches shall contain hose to reach all areas covered by the hydrants that the cache will serve.

4.3.4.2.1.10 Each cache shall contain at least one hose nozzle and one hose wrench.

4.3.4.2.1.11* Caches of fire hose shall be provided at strategic underground locations as follows:

(1) At each intersection with an active submain
(2) At the mouth of each panel
(3) At and on the intake side of each conveyor belt drive
(4) At the entrance to each shop and storage area as defined in 4.2.5, 4.2.8, and 4.2.9
(5) In each operating area
(6) At intervals not to exceed 1524 m (5000 ft) along the main haul route or travelway

4.3.4.2.1.12 Hand hose line systems, if used, shall be installed in accordance with NFPA 14 and shall be a minimum of either 38 mm (1½ in.) lined or 25.4 mm (1 in.) hard rubber.

4.3.4.2.1.13 Hand hose lines that are designated for fire fighting and that have the capability to be used in Class I or Class II liquid storage areas shall be equipped to discharge a foam–water solution and shall be in accordance with the applicable sections of NFPA 11.

4.3.4.2.2* Maintenance. Caches of fire hose shall be checked at least every 6 months to ensure that the inventory of hose, nozzles, wrenches, and adapters is complete, and the following requirements shall apply:

(1) At least one length of hose from each cache shall be pressure-tested annually in accordance with NFPA 1962.
(2) The tested hose shall be tagged and dated so that a different length of hose is tested each year.
(3) If any length of hose fails the pressure test, all lengths of hose in the cache shall be tested.
(4) Hose lines that fail the test shall be replaced.

4.3.4.3 Portable Foam-Generating Devices.

4.3.4.3.1 General Requirements.

4.3.4.3.1.1 Portable foam generators, fire hose, foam concentrate, and emergency fire-fighting materials in accordance with 4.3.4.5 shall be accessible within 60 minutes of fire notification.

4.3.4.3.1.2 Portable foam-generating devices and associated equipment shall be listed or approved for that purpose.

4.3.4.3.2 High-Expansion Foam.

4.3.4.3.2.1 Where high-expansion foam is used, provision shall be made to supply uncontaminated air for foam making.

4.3.4.3.2.2 The foam system shall be tested with the water supply to determine the quality of the foam-making capabilities.

4.3.4.3.3 Maintenance.

4.3.4.3.3.1 At least annually, a thorough maintenance examination of the foam-generating devices and associated equipment, including foam concentrate, shall be made by the mine operator.

4.3.4.3.3.2 Operation of foam-generating equipment during training sessions conducted at least annually shall satisfy the maintenance examination requirement.

4.3.4.4 Rock Dust.

4.3.4.4.1 At least 109 kg (240 lb) of bagged, dry rock dust shall be stored upwind and kept available for fire fighting at or near the following areas:

(1) Maintenance and shop areas
(2) Combustible liquid storage area
(3) Working section
(4) Belt drive area
(5) Belt-head loading area
(6) Ventilation doors on trolley wire–supplied track haulageways

4.3.4.4.2 Where it is impractical to store for fire extinguishment purposes, rock dust shall be permitted to be replaced with an additional portable extinguisher having a nominal capacity of 4.5 kg (10 lb) of multipurpose (ABC) dry-chemical extinguishing agent.

4.3.4.5 Emergency Materials.

4.3.4.5.1 Emergency materials for fighting mine fires shall be near the shaft bottom or other entrance to the mine.

4.3.4.5.2 If the shaft bottom or other entrance to the mine is more than 3.2 km (2 mi) from a working section, additional caches of emergency materials shall be located within 3.2 km (2 mi) of the working section.

4.3.4.5.3 Emergency materials shall include fire hose and necessary adapters, multiple hydrants, wrenches and nozzles, brattice boards and cloth, wood posts, cap pieces, wood wedges, spad guns and spads, or other specialized equipment for installing line brattice, nails, bags of sealant or cement, saws, hammers, axes, shovels, and picks.

4.3.4.5.4 Caches of emergency materials shall be checked at least every 6 months to ensure that the inventory of materials is complete.

4.3.4.6* Training.

4.3.4.6.1 All miners shall be instructed annually in fire prevention and fire-fighting techniques.

4.3.4.6.2 All employees shall be instructed in emergency evacuation procedures.

4.3.4.6.3 All persons who inspect, test, operate, or maintain fire suppression systems shall be trained in the functions they are to perform.

Chapter 5 Surface Mining Operations

5.1 General. This chapter shall cover surface bituminous and subbituminous coal and lignite mining operations.

5.2* Fire Prevention. Risk reduction practices shall follow the principles of minimizing ignition sources and reducing exposure of combustible materials to ignition sources.

5.2.1 Housekeeping.

5.2.1.1 Spills, leaks, excess lubricants, and combustible materials such as oil-soaked wastes, rubbish, and accumulations of environmental debris shall not be allowed to accumulate in quantities that could create a fire hazard.

5.2.1.2 Approved metal receptacles shall be provided where oil-soaked wastes or rubbish are not immediately removed to a safe place for disposal.

5.2.1.3 The storage and handling of flammable or combustible liquids on or within equipment shall be in accordance with NFPA 30.

5.2.1.4 Access to fire protection equipment on mining equipment shall be kept clear of obstructions.

5.2.2 Inspection and Maintenance of Equipment. Hydraulic, coolant, lubrication and fuel lines, and electrical wiring shall be inspected and maintained in accordance with the manufacturers' recommendations.

5.2.3 Flammable and Combustible Liquid Storage on Equipment and in Buildings. Flammable and combustible liquid storage and usage shall be in accordance with Sections 7.3 and 7.4.

5.2.4 Compressed Gas Storage and Usage. Compressed gas storage and usage shall be in accordance with Section 7.1.

5.3 Fire Protection.

5.3.1 Fire protection for the purposes of this standard shall be defined in the broad sense to include fire detection and fire suppression.

5.3.2 Fire suppression systems shall include dry chemical, wet chemical, gaseous, water mist, foam, or sprinklers.

5.3.3 Fire suppression systems and fire alarm systems shall be installed in accordance with applicable NFPA standards.

5.3.3.1 Fire suppression systems shall be tested and maintained in accordance with the appropriate NFPA standard.

5.3.3.2 Water Supplies. Fire suppression water supply shall be of sufficient quantity to extinguish the largest anticipated fire. This shall be accomplished with water trucks in pit areas or fire hydrants in coal processing areas.

5.3.4 Fire Extinguishers for Equipment.

5.3.4.1* A 9.1 kg (20 lb) ABC-type fire extinguisher shall be provided at intervals not to exceed 15.2 m (50 ft) travel distance, including the lower frame areas of draglines.

5.3.4.2 The fire-extinguishing agent applied by hand-portable extinguishers to hazards involving energized electrical equipment shall be nonconductive.

5.3.4.3 Portable extinguishers shall be maintained in accordance with NFPA 10 and kept in their designated places at all times.

5.3.4.4 Extinguishers shall be located on each vehicle and shall be accessible.

5.3.4.5 In areas where obstruction to visual observation cannot be completely avoided, visible markings shall be provided to indicate the location of the fire extinguishers.

5.3.4.6 Extinguishers installed under conditions where they can be subject to physical damage shall be guarded to protect against damage.

5.3.4.7 The installation of an automatic or manually operated fire suppression system shall not eliminate the portable fire extinguisher requirement.

5.3.4.8 Portable fire extinguishers shall be inspected, maintained, and recharged as specified in NFPA 10, Chapter 7, and the following:

(1) Portable fire extinguishers shall be inspected visually at least monthly.
(2) The visual inspection shall ensure the following:
    (a) The extinguisher is in its designated place.
    (b) The tamper seals are intact.
    (c) The extinguisher gauge is in the operable range (if the extinguisher is the stored-pressure type).
    (d) There is no obvious physical damage or condition that will prevent proper operation.
(3) Extinguishers found to be defective or deficient by visual inspection shall be replaced.
(4) Extinguishers shall be subjected to a maintenance examination at least once every year.
(5) Maintenance procedures shall include a thorough examination of the extinguishers, including mechanical parts, extinguishing agent, and expellant.
(6) Any troubles or impairments shall be corrected.
(7) All extinguishers shall be recharged after use in accordance with the manufacturer's recommendations.
(8)*Each extinguisher shall have a permanent tag attached on which the inspection date shall be recorded.

5.3.4.9 Portable extinguishers shall be tested hydrostatically at intervals not exceeding those specified in NFPA 10, Chapter 8.

5.3.5 Draglines, Electric Shovels, and Hydraulic/Electric Excavators.

5.3.5.1 Center Pin/Collector Ring Area.

5.3.5.1.1 An automatic fire suppression system shall be installed in the center pin/collector ring area of the dragline. If an electrical spark cannot communicate from the collector ring (e.g., a sealed ring) to the grease around the center pin, a fire suppression system is not required.

5.3.5.1.2 An automatic fire suppression system shall be installed in the ring gear area of shovels.

5.3.5.1.3 Suppression system alarms shall be transmitted to the operator's cab. An audible and visual alarm shall be provided.

5.3.5.1.4 A manual actuator shall be provided just outside the center pin/collector ring area.

5.3.5.2 Hydraulics.

5.3.5.2.1* An automatic fire suppression system shall be installed to protect hydraulic pump(s), hydraulic control valves, associated lines and equipment in the hydraulic pump area, and other areas where fires can propagate to.

5.3.5.2.1.1 If approved fire-resistive hydraulic fluid is used, then a fire suppression system is not required.

5.3.5.2.1.2 If an ignition source is not readily available, then a fire suppression system is not required.

5.3.5.2.2* The system shall send audible and visual alarms to the operator's cab.

5.3.5.2.3 A manual actuator shall be located just outside the hydraulic compartment area.

5.3.5.3 Lube Oil Pumping and Storage.

5.3.5.3.1* Automatic lube oil systems that are located in a segregated room shall be provided with an automatic fire suppression system.

5.3.5.3.2 The system shall send an audible and visual alarm to the operator's cab.

5.3.5.3.3 A manual actuator shall be located just outside the lube oil room.

5.3.5.3.4 Lube oil rooms shall have automatic door closers or shall have the door interlocked to shut upon actuation of the fire suppression system.

5.3.5.4 Transformers.

5.3.5.4.1 Oil-filled transformers located in the tail section, enclosed rooms, or other inaccessible locations shall be provided with an automatic fire suppression system.

5.3.5.4.1.1 The system shall transmit an audible and visual alarm to the operator's cab.

5.3.5.4.1.2 A manual actuator shall be located just outside the transformer area.

5.3.5.4.2* Transformers located in areas other than those listed in 5.3.5.4.1 shall be protected with a Class BC, minimum 45.4 kg (100 lb), fire extinguisher.

5.3.5.4.3 Oil analysis, including dissolved gas, shall be conducted on combustible oil-filled transformers based upon manufacturer's recommendations or ANSI/NETA MTS-,*Standard for Maintenance Testing Specifications for Electrical Power Distribution Equipment and Systems*, whichever is more stringent.

5.3.5.4.4 Thermographic scanning shall be performed on transformers at least annually.

5.3.5.5 Electrical Room or Cabinet.

5.3.5.5.1 Enclosed electrical rooms shall be protected with a total flooding gaseous extinguishing agent or equivalent fire suppression system.

5.3.5.5.1.1 The system shall be installed in accordance with NFPA 2001 or other applicable NFPA standards.

5.3.5.5.1.2 The system shall be actuated by a smoke, ultraviolet/infrared (UV/IR), or heat detector system and send an audible and visual alarm to the operator's cab.

5.3.5.5.1.3 The ventilation system shall be interlocked to the gaseous extinguishing system to shut down upon first detection.

5.3.5.5.1.4 The room shall be sealed to maintain the design gaseous extinguishing concentration.

5.3.5.5.1.5 Pre-discharge alarms shall be provided in rooms provided with automatic suppression systems.

5.3.5.5.2 Electrical rooms shall be maintained at a positive pressure to reduce the chances of dust entering the room.

5.3.5.5.3 Electrical cabinets shall be protected with a gaseous fire suppression system or equivalent fire protection system.

5.3.5.5.3.1 The system shall be installed in accordance with NFPA 2001 or other applicable NFPA standards.

5.3.5.5.3.2 The system shall be actuated by a smoke, UV/IR, or heat detector system and send an audible and visual alarm to the operator's cab.

5.3.5.5.4* Thermographic scanning shall be performed on the electrical switchgear and motor starters at least annually.

5.3.5.6 Manual Extinguishing Equipment.

5.3.5.6.1 Minimum 45.4 kg (100 lb) A:B:C-type extinguishers shall be accessible to persons on the main deck of the dragline.

5.3.5.6.2 The location and number of extinguishers shall be determined by what is practical for the machine.

5.3.6 Hydraulic/Diesel Excavators.

5.3.6.1 An automatic fire suppression system shall be provided to protect the engine compartment, hydraulic pumps, and associated equipment.

5.3.6.1.1 For hydraulic systems above 567.8 L (150 gal) in the lines, a dual agent system shall be provided.

5.3.6.1.2 A manual actuator shall be located in the operator's cab and at the means of egress from the machine.

5.3.6.2 The machine shall be interlocked to shut down upon discharge of the extinguishing system.

5.3.6.3 A means shall be provided to automatically relieve the hydraulic pressure upon discharge of the extinguishing system.

5.3.6.4 Adequate fire resistance shielding shall be provided between the hydraulic hoses and the turbocharger and engine manifold to prevent hydraulic fluid from being sprayed on hot mechanical parts.

5.3.6.5 The fire detection electrical wiring within fire hazard areas, such as battery compartments, engine compartments, and so forth, shall be outfitted with a fire-resistant sleeve.

5.3.6.6* Fire-suppression system manual actuation lines shall not be routed near high heated surfaces and shall not be routed within fire hazard areas unless fitted with fire-resistant sleeves.

5.3.7 Mobile Equipment.

5.3.7.1 Fire Protection. Portable extinguishers installed on mobile mining equipment, including but not limited to mobile generators and compressors, shall have a minimum rating of 2-A:10-B:C and a nominal capacity of 2.3 kg (5 lb) of extinguishing agent.

5.3.8 Self-Propelled Equipment.

5.3.8.1 Portable Fire Extinguishers.

5.3.8.1.1* All self-propelled surface mining equipment, including but not limited to bulldozers, front-end loaders, haulage trucks, cranes, graders, scrapers, draglines, drills, shovels, and diesel and electrical equipment, shall be equipped with at least one listed portable, multipurpose (ABC), dry-chemical extinguisher having a nominal capacity of 4.5 kg (10 lb) of agent or greater.

5.3.8.1.2 Portable extinguishers installed on small units of self-propelled mining equipment, including but not limited to miniature loaders and individual personnel transports, shall have a minimum rating of 2-A:10-B:C and a nominal capacity of 2.3 kg (5 lb) of extinguishing agent.

5.3.8.2 Fire Detection.

5.3.8.2.1 Fire detectors shall be permitted to be used to initiate audible or visual warning, automatic actuation of a fire suppression system, or equipment shutdown.

5.3.8.2.2 Fire detectors shall be tested and listed for the application.

5.3.8.2.2.1 If fire detectors are used with a pre-engineered fire suppression system then they shall be included in the fire suppression system listing.

5.3.8.2.3 Compartment sizes and contours, airflow patterns, obstructions, and other characteristics of the protected area shall determine the placement, type, sensitivity, durability, and, where applicable, number of detectors.

5.3.8.2.4 All fire detection systems and applicable equipment shall be tested after installation in accordance with *NFPA 72* and fire suppression systems standards.

5.3.8.2.4.1 It shall not be necessary for testing to require the discharge of any associated fire suppression system.

5.3.8.2.5* At least every 6 months, all fire detection systems, including alarms, shutdowns, and other associated equipment, shall be thoroughly examined and checked for proper operation in accordance with the manufacturer's recommendations.

5.3.8.2.5.1 Any equipment found deficient shall be repaired or replaced, and the system retested for operation in accordance with the manufacturer's instructions.

5.3.8.2.6 Between the maintenance examinations or tests, the detection system shall be inspected visually, in accordance with an approved schedule necessitated by conditions as determined by the mine operator.

5.3.8.3 Fixed Suppression Systems.

5.3.8.3.1 Haul trucks with a capacity of over 77 metric tons (85 tons) shall have a fixed fire suppression system protecting the engine compartment and hydraulic pump and other hazard areas.

5.3.8.3.2* Other large mining equipment such as but not limited to dozers, endloaders, drills, graders, and scrapers shall have a fixed fire suppression system protecting the engine compartment and hydraulic pump and other hazard areas.

5.3.8.3.3 Mining equipment requiring a fire suppression system shall be protected by a system to suppress potential fires in the protected areas and shall comply with the following:

(1) The fire suppression system shall be listed or approved for the purpose.
(2) Where installed, the equipment shall be located or guarded so as to be protected against physical damage.
(3) Fire suppression systems shall be automatically actuated.
(4)*Automatically actuated systems shall also have a manual actuator capable of being activated from the operator's compartment or other location.
(5) Agent distribution hose or pipe shall be secured and protected against damage, including abrasion and corrosion.
(6) Except for automatic sprinkler systems, discharge nozzles shall be protected against entrance of environmental debris, including moisture, dust, dirt, or insects, by blow-off caps or other similar devices or materials.
(7) Except for automatic sprinkler systems, the nozzle cover shall open or blow off upon discharge of the system.
(8) The automatic fire suppression system shall be installed so that system actuation causes shutdown of the protected equipment.
(9) Up to a 30-second delay shall be included in the design of the interlock system for the operator to maintain control of the equipment.

5.3.8.3.4 A standby source of power shall be provided where electrical power is the only means of fire suppression system actuation.

5.3.8.3.5 All fire suppression equipment and systems shall be tested after installation in accordance with the manufacturer's or designer's recommendations.

5.3.8.3.5.1 Testing shall not require the discharge of suppressant unless there is no other manner in which the reliability and integrity of the system can be verified.

5.3.8.3.6 An installation-and-maintenance or owner's manual that describes system operation and maintenance requirements shall be provided for all fire suppression equipment.

5.3.8.3.7* In accordance with the manufacturers' or designers' recommended inspection and maintenance procedures and schedules, but not to exceed every 6 months, all fire suppression systems, including alarms, shutdowns, and other associated equipment, shall be thoroughly examined and checked for proper operation by trained and competent personnel.

5.3.8.3.7.1 Any equipment found deficient shall be repaired or replaced, and the system retested for proper operation.

5.3.8.3.7.2 Between regular maintenance examinations or tests, the system shall be inspected visually, in accordance with the manufacturer's or designer's recommended schedule.

5.3.8.3.7.3 Testing shall be in accordance with the applicable NFPA standards.

5.3.8.3.8 Fire suppression systems shall be maintained in operating condition at all times.

5.3.8.3.9 Use, impairment, and restoration of the system shall be reported to the mine operator.

5.3.8.3.10 All persons who can be expected to inspect, test, maintain, or operate a fire suppression system shall be trained to perform their intended tasks.

5.3.8.3.11 Where inadvertent discharge of the fire suppression system during servicing could result in injury to personnel, provisions shall be made to safeguard against accidental actuation of the system.

5.3.8.3.12 All operators, supervisors, and maintenance personnel of self-propelled and mobile equipment shall be trained in the use of fire suppression equipment.

Chapter 6 Coal Processing

6.1 General. This chapter covers coal preparation, crushing, screening, and drying.

6.1.1 Materials and Construction.

6.1.1.1 Coal mine surface buildings and structures, housing, and supporting coal-processing and coal-handling equipment shall be of noncombustible construction.

6.1.1.2 Dry coal screening, crushing, dry cleaning, and other operations producing coal dust shall be conducted in open structures to prevent the accumulation of dust concentration levels that can create explosion hazards.

6.1.1.2.1 Where open structures are impractical, enclosed buildings shall be provided with explosion venting in accordance with 6.2.3 and shall be located so as to minimize fire and explosion exposure to major buildings and equipment.

6.1.1.2.2 Location of the processes described in 6.1.1.2 in the main plant building shall be permitted, provided the dust-producing area is equipped with explosion venting in accordance with 6.2.3 and is separated from the remainder of the building by construction designed to withstand the pressure buildup from an explosion prior to pressure relief by means of explosion vents.

6.1.2 Coal Dust Control.

6.1.2.1 Dedusters.

6.1.2.1.1 All dedusting equipment shall be connected directly to a suction system capable of moving enough air to prevent the leakage of dust from the system.

6.1.2.1.2 The suction system shall discharge the dust-laden air by the shortest possible route to collectors outside the building.

6.1.2.2* Pneumatic Cleaners.

6.1.2.2.1 Dust-collecting systems with suction hoods at the cleaners, suction ducting that maintains at least a 20 m/sec (4000 ft/min) air velocity, and dust collectors having pressure release venting shall be installed.

6.1.2.2.2 Belt conveyor–type transfers and loading points associated with the cleaners shall be hooded similarly and connected to dust collectors.

6.1.3 Coal Storage. Coal storage facilities shall be in accordance with 9.5.2.

6.2 Fire and Explosion Prevention.

6.2.1 Electrical Classification of Hazard.

6.2.1.1 Plant areas of open construction where coal dust or any combustible gases liberated from the coal are dispersed to the open atmosphere shall be classified nonhazardous.

6.2.1.2 Plant areas isolated from the coal process, such as control rooms, electrical equipment rooms, or substations, that are provided with ventilation to prevent the accumulation of combustible gases or coal dust shall be classified nonhazardous.

6.2.1.3 Enclosed areas of processing plants where coal is wet to prevent particles from becoming airborne or where dry coal dust does not accumulate shall be classified nonhazardous.

6.2.1.4* Enclosed areas where the failure or malfunction of the ventilation would result in the accumulation of explosive concentrations of methane gas shall be designated as Class I, Division 2 locations in accordance with Article 500 of *NFPA 70*.

6.2.1.4.1* Electrical equipment approved as "permissible" by the Mine Safety and Health Administration (MSHA) shall be acceptable in locations classified Class I, Division 1.

6.2.1.5 Areas of a processing plant normally designated as Class I shall be permitted to be considered nonhazardous, provided the following conditions are met:

(1) Ventilation to prevent an accumulation of an explosive or ignitible mixture of gases
(2) Failsafe continuous methane monitoring designed to sound an alarm when the methane–air mixture reaches 20 percent of the lower explosive level (LEL) or 1 percent methane by volume
(3) An interlock to stop the process equipment automatically when the methane–air mixture reaches 40 percent of the LEL or 2 percent methane by volume
(4) An electrical system arranged so that when methane concentrations reach 40 percent of the LEL, all electrical circuits including control circuit conductors are deenergized
(5) Any equipment that is needed to restore the plant to a methane–air mixture of less than 20 percent of the LEL or 1 percent methane by volume, such as lighting, ventilation, or sump pumps, installed in accordance with Class I, Division 1 requirements

6.2.1.6* Enclosed areas in which coal dust is not in suspension in explosive or ignitible quantities or in which coal dust might be present in explosive or ignitible quantities or might be in suspension in the air due to a malfunction shall be designated as Class II, Division 2 in accordance with Article 500 of *NFPA 70*.

6.2.1.7* The structure of a preparation plant shall be connected to a common electrical ground.

6.2.1.7.1 Any electrical equipment that is mounted on a concrete pad shall be grounded to the metal structure with a shunt.

6.2.1.7.2 Where the structure is nonmetallic, a separate grounding grid for equipment shall be provided.

6.2.1.8 Positive pressure shall be maintained in process control rooms to prevent the entry of fugitive dust.

6.2.1.9 Electrical Equipment Rooms. Positive pressure shall be maintained in electrical equipment rooms, such as switchgear rooms, motor control centers, and cable-spreading rooms, that have a potential for fugitive dust entry.

6.2.1.9.1 Thermographic scanning shall be performed on switchgear and motor starters on an annual basis.

6.2.1.10 Tools that are actuated by electrical power shall not be used in areas with explosive gases or dusts.

6.2.1.11 Transformers. Oil analysis, including dissolved gas, shall be conducted on combustible oil-filled transformers based upon manufacturer's recommendations or ANSI/NETA MTS, *Standard for Maintenance Testing Specifications for Electrical Power Distribution Equipment and Systems*, whichever is more stringent.

6.2.1.12 A smoke detector system shall be provided in MCC rooms or other critical electrical rooms. The system shall be installed in accordance with *NFPA 72* and send an alarm to a constantly attended location.

6.2.2 Dust Collectors and Dust Removal Equipment.

6.2.2.1 Dust collectors or dust suppression systems using water-based sprays shall be used to reduce dust in suspension at coal transfer points.

6.2.2.2 Those areas in which combustible dust is or might be in suspension in the air continuously, intermittently, or periodically under normal operating conditions shall be provided with a dust-collecting system or systems to collect such dust and prevent its discharge to the atmosphere.

6.2.2.2.1 All coal-handling equipment or machinery that produces dust shall be connected to a dust collector with ducts and hoods that are designed to provide suction volume and velocity to collect and transport all the dust produced.

6.2.2.2.2 Hoods, enclosures, and ducts shall be of noncombustible construction, designed and maintained in accordance with NFPA 91.

6.2.2.2.3 All dust collectors, other than those that are an integral part of dust-producing equipment, shall be located outside the working areas, preferably outside the building or in separate rooms that are vented to the outside.

6.2.2.3 When a plant or handling facility is planned, special consideration shall be given to the location of the dust-producing equipment with respect to the location of the dust collection devices to ensure that the connecting ducts will be as straight and as short as possible.

6.2.2.3.1* All dry dust collectors shall be of noncombustible construction, equipped with explosion doors or vents.

6.2.2.3.2 The entire dust-collecting system shall conform to NFPA 91.

6.2.2.4 In no case shall the design of the dust removal system be such that the dust is drawn through the fan before entering the collector. Fans shall be of noncombustible construction.

6.2.2.5* Ducts shall be designed to maintain a velocity of not less than 22.9 m/sec (4500 ft/min) to ensure the transport of both coarse and fine particles and to ensure re-entrainment if for any reason the particles should fall out before delivery to the dust collector (e.g., in the event of a power failure).

6.2.2.5.1 In bag-type dust collectors, the bags shall be constructed of antistatic, fire-resistant material and shall be provided with an electrical ground.

6.2.2.5.2 Dust collector hoppers shall be sloped at approximately 60 degrees to ensure material flow.

6.2.2.5.2.1 Zero-speed switches and high-level alarms shall be used to identify conditions that can lead to spontaneous combustion.

6.2.2.5.2.2 Hopper discharge valves or screw conveyors shall be provided to discharge the dust continually.

6.2.2.5.2.3 Hoppers shall not be used as storage bins.

6.2.2.5.3 Hood takeoffs shall have a minimum area of four times the area of the duct.

6.2.2.5.3.1 Ductwork also shall be supplied with blast gates and dampers for individual pickup volume adjustment.

6.2.3 Explosion Venting.

6.2.3.1* Explosion venting shall be provided in areas where coal dust might be present in explosive or ignitible quantities, such as in coal preparation plant buildings, and in sections of buildings housing screens, pneumatic coal-cleaning equipment, dryers, and other dust-producing machinery.

6.2.3.2 Ventilating hoods and exhaust ducts shall not be acceptable as explosion-venting devices unless they are designed for a dual purpose and function to provide direct release of excess pressure to the outside.

6.2.3.3 Equipment vents or ducts used to direct the energy of an explosion in equipment to the outside of the building or a safe location shall be as short as possible and shall be designed to withstand the explosion pressure.

6.2.3.3.1 Vent closures, which might be necessary to permit proper functioning of equipment and to prevent the escape of dust during normal operation, shall be designed to open at the lowest possible increase in pressure or shall be of flexible or frangible materials that blow out or rupture to permit the release of explosion pressure.

6.2.4* Flammable and Combustible Liquids and Liquefied Petroleum Gas. Flammable and combustible liquids and compressed gases shall be stored and used in accordance with Chapter 7.

6.2.5 Maintenance. The user shall have responsibility for establishing a maintenance program that ensures that equipment is in working order.

6.2.5.1 All coal-handling equipment and machinery shall be maintained in accordance with the manufacturers' recommendations.

6.2.6 Housekeeping. Provision shall be made for cleaning to prevent the accumulation of coal dust.

6.2.6.1 Combustible waste materials shall not be permitted to accumulate in locations where a fire or an explosion hazard can be created.

6.3* Preparation Plants and Crusher Buildings. This section shall apply to preparation plants, tipples, crushers inside buildings, and crushers in belowgrade areas. Open air crushers do not pose a significant hazard and shall be excluded from the requirements of this section.

6.3.1 Building Construction.

6.3.1.1 Buildings and equipment shall be shaped, installed, or protected so as to minimize the surface area on which coal dust can accumulate.

6.3.1.2 Access for cleaning or washing down shall be provided.

6.3.1.3 Access platforms or walkways installed between floors shall be permitted to be open-grid construction to facilitate cleaning.

6.3.1.4 Walls or partitions isolating sections of the plant that contain dust-producing operations shall be constructed and installed to minimize the transmission of dust to adjacent areas.

6.3.1.5 To prevent the accumulation of dust on exposed wall or partition framing, metal siding or other equivalent material shall be installed on the side facing the dust-producing section.

6.3.1.6 Doors in the walls or partitions required by 6.3.1.4 shall be self-closing.

6.3.1.7 Drain systems shall be provided in areas where cleaning is accomplished by washing down.

6.3.1.8 Two remote means of egress shall be provided on each floor of the plant.

6.3.1.9 Emergency lighting shall be provided at the means of egress stairways in accordance with NFPA *101*, Section 7.9.

6.3.1.10* Emergency exit signs shall be provided at the means of egress stairways in accordance with NFPA *101*, Section 7.10.

6.3.1.11 If lightning protection is required, it shall be in accordance with NFPA 780.

6.3.1.12 Electrical Equipment. Transformers, switchgear, motor starters, and other electrical equipment shall be installed in accordance with *NFPA 70*.

6.3.1.12.1* Transformers located outside of the preparation plant shall be far enough away or provided with a fire barrier wall and containment or drainage to limit damage to the building if the transformer were on fire.

6.3.1.12.2* Combustible oil-filled transformers located inside the preparation plant shall be enclosed in a transformer vault constructed in accordance with *NFPA 70*.

6.3.1.12.3* Where a combustible oil-filled transformer is located on the roof of the preparation plant, it shall be provided with a fire barrier and spill containment to limit fire damage to the building.

6.3.2 Fire Protection.

6.3.2.1 Portable Extinguishers.

6.3.2.1.1 Every building or room of a plant where combustible material is present or dry coal is processed or handled shall be provided with approved portable multipurpose fire extinguishers.

6.3.2.1.2 The number of approved portable extinguishers, their type, and their distribution shall be in accordance with NFPA 10 except that the smallest extinguisher shall have a nominal capacity of 9.1 kg (20 lb) of agent and a minimum rating of 10-A:60-B:C.

6.3.2.1.3 Extinguishers employing agents having a B:C rating shall be permitted to be used if the hazard is confined solely to electrical equipment.

6.3.2.2 Fixed Fire Protection Systems.

6.3.2.2.1* Where required by the authority having jurisdiction, fixed fire protection systems shall be provided and shall be designed in accordance with the appropriate NFPA standards, depending on the agent utilized.

6.3.2.2.1.1 Where a pre-engineered fire suppression system is used, it shall be designed and installed in accordance with the fire suppression system manufacturer's listed installation and maintenance manual.

6.3.2.2.2 Working plans for the fixed fire protection system shall be submitted for approval to the authority having jurisdiction.

6.3.2.2.3 Combustible hydraulic and lube oil systems that exceed 94.6 L (25 gal) and are located in below-grade areas shall be protected by an automatic fire suppression system.

6.3.2.3 Standpipe and Hose Systems.

6.3.2.3.1* Class III standpipe systems shall be provided in all coal preparation plants and crusher buildings in accordance with NFPA 14.

6.3.2.3.2 When automatic sprinkler systems are to be supplied through the standpipe system, hydraulic calculations shall be used to ensure that the piping and the water supply meet the hose and automatic sprinkler demands simultaneously.

6.3.2.3.3 Hose stations on or in conveyor galleries shall be provided with hoses that are of length equal to the distance between water supply connections.

6.3.2.3.4 Fire hose shall be provided in an accessible area in order to fight a fire involving spirals.

6.3.2.4 Water Supply.

6.3.2.4.1* Availability. An available supply of water shall be provided for fire protection systems and manual fire-fighting purposes.

6.3.2.4.2 Fire Mains. Where fire mains and hydrants are provided, the water supply system shall be installed and maintained in accordance with NFPA 24.

6.3.2.4.3 Other Water Supplies. Where public or private fire mains are not provided, alternative water supplies complying with NFPA 1142 shall be provided.

6.3.2.4.4* Capacity.

6.3.2.4.4.1 The water supply capacity shall be capable of providing the estimated water needed for fire-fighting purposes for a minimum duration of 2 hours.

6.3.2.4.4.2 Water pumps installed as part of a process water system and designed for the calculated flows and pressures required for fire fighting shall be permitted to be used to supply fire mains.

6.3.2.5 Inspection and Maintenance of Fire Protection Equipment.

6.3.2.5.1 Portable extinguishers shall be maintained in accordance with NFPA 10.

6.3.2.5.1.1 Fire extinguishers shall be inspected on a 6-month basis.

6.3.2.5.2 Water-based fire protection systems shall be maintained in accordance with NFPA 25.

6.3.2.5.3 Any fire protection system, including sprinklers, installed in accordance with the requirements of this standard shall be maintained to provide assurance that the system will operate.

6.3.2.5.4 All persons who inspect, test, or maintain fixed fire protection systems shall be trained in accordance with the appropriate NFPA standards and the manufacturers' specifications.

6.3.2.6 Surveillance.

6.3.2.6.1 Periodic surveillance for fire hazards shall be conducted when the plant, or any part thereof, is not in operation or not constantly attended.

6.3.2.6.2 Frequency of surveillance shall be dependent on the type of coal product involved and its susceptibility to self-heating and other site conditions.

6.3.2.6.3* Smoke detectors shall be provided in electrical equipment rooms.

6.3.2.6.3.1 Fire alarm systems shall be installed in accordance with *NFPA 72*.

6.3.2.6.3.2 Audio and visual notification alarms shall be provided in the area, and the signal shall be transmitted to a constantly attended location.

6.4 Dryers.

6.4.1* General.

6.4.1.1 Thermal coal-drying systems shall be located at least 30.5 m (100 ft) from any underground coal mine opening.

6.4.1.2 Dryers that have been idle for more than 30 days or shut down because of a fire or any other emergency condition during normal operation shall be checked to ensure that there is no burning material within the system before being placed back in service.

6.4.2 Loss Prevention Design Features. Dryer heating units that are fired by pulverized coal shall be installed, operated, and maintained in accordance with NFPA 85.

6.4.2.1 Dryers of the direct-fired type shall be designed and operated so that combustion is complete as possible within the furnace/air heater before the gases of combustion come in direct contact with the coal drying in the drying chamber.

6.4.2.2 Dryers shall be designed and constructed to be dust-tight, with smooth surfaces to prevent the accumulation of coal.

6.4.2.3 Where coal can be exposed to excessive heat on normal or emergency shutdown, a bypass stack with an automatically controlled damper shall be installed to direct the products of combustion away from the coal.

6.4.2.4 Thermal dryer systems that have a hot gas inlet or plenum chambers where fly ash or coal siftings might accumulate shall be equipped with drop-out doors or ports to facilitate removal of these solids.

6.4.2.4.1 Where continuous means of removing drop-out solids are not provided, checking and manual clean-out shall be provided as conditions warrant.

6.4.2.5* All internal areas of thermal coal dryers where coal solids could possibly hang up or accumulate under any abnormal operating condition, such as in the drying chamber or dry cyclone collector, shall be equipped with explosion relief vents that open directly to the outside atmosphere.

6.4.2.5.1 These explosion relief vents shall be of the quantity, size, and location to operate in excess of the design normal pressure.

6.4.2.5.2 Explosion vents shall be checked or tested at least once each month, and records kept to verify these checks.

6.4.2.5.3 Explosion vents shall be directed away from personnel work areas and walkways.

6.4.2.6 During system operation, visual checks shall be made of all the mechanical components and equipment associated with the drying system as conditions warrant.

6.4.2.7* Indirect heat exchange–type dryers, such as thermal disk processors, shall be given special consideration in the design of fire protection for the dryer and dryer building.

6.4.3 Instrumentation and Control.

6.4.3.1 Instrumentation and control panels on thermal dryers shall be located in an area relatively free of moisture, vibration, dust, and noise.

6.4.3.2 The panel shall be located within the range and view of the supervising operator.

6.4.3.3 The operator control room shall be provided with windows or other means, such as video cameras, that give visual contact with the thermal drying system.

6.4.3.4 The panel shall include recording-type control instruments, monitoring indicators, alarms, and temperature limits set to maintain normal operation.

6.4.3.5 Audible and visual alarms shall be interlocked electrically to provide shutdown of the drier when temperatures are exceeded or other emergency malfunctions occur.

6.4.3.6 Control instruments shall be checked and serviced by a technician at least every 3 months.

6.4.3.7 Where pneumatic controls are used, instrument quality air shall be provided.

6.4.3.8 A schematic diagram showing the locations of thermocouples, pressure taps, and other controls shall be posted at the control panel.

6.4.3.9 Written procedures, including start-up, normal shutdown, and emergency shutdown procedures, shall be provided and posted at the control panel.

6.4.3.10 All main fans shall be inspected and shall have bearing temperature and vibration detectors.

6.4.3.11 Coal feed bins shall have low-level alarms.

6.4.4 Fire Protection for Drying Chambers. Drying chambers shall be protected by an automatic water spray system.

6.4.4.1 The automatic spray system shall include a manual control.

6.4.4.2 The source for the fire protection water shall be such that the required volume flow rate and pressure of clean (solid-free) water are available at all times and that the exposed piping is protected against freezing.

6.4.5* Explosion Venting.

6.4.5.1 Buildings shall be provided with explosion venting in accordance with NFPA 69 and shall be located to minimize fire and explosion exposure to other buildings and equipment.

6.4.5.2 Cyclone collectors used with dryers shall be equipped with explosion vents equal in size to the cross-sectional area of the exhaust sleeve to supplement the venting area provided at the exhaust opening.

6.4.5.3 Dryers shall be designed and installed, if possible, with their explosion vents opening directly to the outside.

6.4.5.3.1 This venting shall be permitted to be accomplished by installation of the dryer along an outside wall of the building, directly under the roof, or by a portion of the dryer being extended through the roof.

6.4.5.3.2 If such locations are not practicable, ducts to the outside of the building shall be as short as possible and designed to withstand explosion pressure.

6.4.5.3.3 Access floors, platforms, walkways, and stairs on the thermal dryer structure shall be located so that personnel are not in the line of an explosion vent.

6.5 Conveyors. Conveyors shall be in accordance with Section 9.1.

6.6 Mobile Equipment. Mobile equipment used in coal processing areas shall conform to 5.3.7.

Chapter 7 Storage and Use of Compressed Gases and Flammable and Combustible Liquids

7.1* Compressed Gas Storage and Usage — Cutting and Welding.

7.1.1 Procedures and Maintenance of Equipment.

7.1.1.1 Cutting and welding shall be performed only by persons who have been task trained.

7.1.1.2 Personal protective equipment shall be worn by personnel during welding or flame cutting operations.

7.1.1.3 Before any cutting or welding is performed, prior approval shall be granted by management or its designated agent.

7.1.1.4 Compressed gas shall be used only for its intended purpose.

7.1.1.5 Compressed oxygen shall not be used to blow coal dust from clothing or machinery.

7.1.1.6 Manifolding of cylinders containing gases used for cutting and welding shall be permitted only in shops ventilated with sufficient quantity and velocity to dilute, render harmless, and clear away flammable or explosive concentrations of vapors.

7.1.1.7 When not in use, the compressed gas cylinder valve shall be closed.

7.1.1.8 Cutting and welding equipment shall be maintained in operating condition with all safeguards in place and functioning.

7.1.1.9 Flashback and backflow preventers shall be installed at the outlets of all pressure regulators and on the hose connections used in cutting, welding, brazing, and soldering torches.

7.1.2 Fire Prevention and Control.

7.1.2.1* Cutting or welding shall not be performed on or within containers or tanks that have stored combustible or flammable materials until such containers or tanks have been purged and cleaned or have been inerted.

7.1.2.2 Cutting or welding shall not be performed within 15.2 m (50 ft), measured horizontally, of explosives, blasting agents, or flammable or combustible liquid storage areas unless separated by a noncombustible barrier.

7.1.2.3 Electrical cutting and welding equipment shall be electrically grounded.

7.1.2.4 All machinery and operations producing combustible dust within range of welding sparks shall be shut down prior to the start of the welding or cutting operation and shall remain inoperative until a final inspection is completed.

7.1.2.5* Before cutting and welding operations are undertaken, the following precautions shall be observed:

(1) The immediate area shall be cleaned and cleared of combustible material and, if underground, wetted down with water or coated with rock dust.
(2) Open gear cases and combustible machine components located within 7.6 m (25 ft) of cutting or welding operations shall be covered with noncombustible material.
(3) Fire-extinguishing equipment, including fully charged and operable multipurpose (ABC) dry-chemical extinguishers, rock dust, or water hose, shall be within 7.6 m (25 ft) of the cutting or welding operation.
(4) In the case of a portable fire extinguisher, a single unit having a nominal capacity of 9.1 kg (20 lb) with a minimum rating of 4-A:40-B:C shall be within 7.6 m (25 ft) of the cutting or welding operation.
(5) Tests for methane gas (CH_4) shall be made before cutting or welding in any area where methane gas is likely to be present, and the following shall apply:
    (a) Cutting or welding shall not be permitted to begin or continue unless the concentration of methane gas is less than 1 percent by volume.
    (b) Methane concentration shall be continuously monitored during the cutting and welding operation.
(6) Where cutting or welding is necessary inby the last open crosscut, a continuous fire watch shall be maintained.
(7) Where inby equipment to be modified or repaired can be moved, it shall be moved outby the last open crosscut before cutting or welding.
(8) Ventilation shall be established prior to and maintained during cutting or welding.
(9) Flammable and combustible liquids shall not be dispensed within 15.2 m (50 ft) of cutting or welding operations.
(10) Freshly painted surfaces shall be permitted to dry so that ignitible vapor is not present before cutting or welding.
(11) When conducting cutting and welding operations inside buildings, in draglines, or underground, a permit shall be prepared and signed by the person performing the work and by an individual designated by management to authorize cutting and welding operations.

7.1.2.6 Combustibles posing a fire hazard shall be relocated or protected with a fire-retardant cover or fire-retardant barrier.

7.1.2.7 Where welding or cutting with an arc or a flame is performed where combustible materials are present and cannot be removed or protected from ignition sources, a fire watch shall be provided.

7.1.2.7.1 Where a fire watch is required, it shall be maintained for a minimum of 30 minutes after completion of cutting or welding operations to detect and extinguish smoldering combustibles.

7.1.2.7.2 The fire watch shall have fire-extinguishing equipment available and be trained in its use.

7.1.2.7.3 Fire watchers shall be familiar with the facilities and the procedures for sounding an alarm in the event of a fire.

7.1.2.8 Openings or cracks in walls, partitions, floor decks, or ducts shall be covered tightly with a noncombustible material to prevent the passage of sparks to adjacent areas.

7.1.2.9 Where welding is being performed on a metal wall, partition, ceiling, or roof, precautions shall be taken to prevent ignition of combustibles on the other side due to conduction or radiation.

7.1.2.10 In confined spaces, positive ventilation shall be established prior to start-up of cutting or welding operations.

7.1.2.11 Noncombustible barriers shall be installed below welding or cutting operations that are being performed in or over shafts, silos, and similar openings.

7.1.2.12 Inspection.

7.1.2.12.1 Inspection for sparks, smoldering material, and fire shall be made during cutting or welding.

7.1.2.12.2 After completion of the work, a search of the area, including the floors above and below, shall be made for fires and for development of smoldering fires.

7.1.3 Underground Transport. Compressed gas cylinders for cutting or welding shall be transported as follows:

(1) The cylinders shall be disconnected from regulators.
(2) The cylinders shall be protected with a metal cap or headband (fence-type metal protector around the valve stem).
(3) The cylinders shall be secured by devices that will hold them in place during transit.
(4) The cylinders shall be placed in electrically insulated, substantial containers designed to hold the cylinders during transit on a trolley wire haulage system.
(5) The cylinders shall be labeled "empty" or "MT" if the gas has been expended.

7.1.4 Underground Storage. Compressed gas cylinders stored underground shall meet all the requirements of Section 7.1.

7.1.4.1* Compressed gas cylinders shall be clearly marked using the designations of the U.S. Department of Transportation (DOT).

7.1.4.2 Compressed gas cylinders shall be placed in storage areas that shall be designated for the purpose, constructed of noncombustible material or rock-dusted, and free of trash and combustible or flammable liquids.

7.1.4.3 Compressed gas cylinders shall be stored and secured in an upright position or angled with the valve end elevated.

7.1.4.4 Compressed gas cylinders shall be protected against damage from the following:

(1) Falling material
(2) Contact with power lines and energized electrical machinery
(3) Heat from cutting or welding operations

7.1.4.5 The valves of the compressed gas cylinder shall be closed and protected from physical damage when not in use.

7.1.4.5.1 Hoses from compressed gas shall have flash arresters on the regulator side and shall be drained after use.

7.1.4.6 Compressed gas cylinders shall not be stored or left unattended inby the last open crosscut.

7.1.4.7 Where located in other than underground shops, compressed gas cylinders not in use shall have the regulators removed, and the valves shall be protected by being covered with protective metal caps, by tank design, or by other approved equivalent protection.

7.1.4.8 Flammable compressed gas shall be segregated from oxygen by a fire-resistive barrier (e.g., steel plating or concrete blocks) or by a distance of 6.1 m (20 ft).

7.1.5 Surface Storage.

7.1.5.1 Storage of compressed gases on an excavating machine shall be limited to that used on a daily basis.

7.1.5.2 Acetylene, oxygen, and other compressed gas cylinders shall be kept in the upright position and secured against falling over.

7.1.5.3 A metal or caged barrier shall be provided above cylinders in storage if there is the potential for falling objects.

7.1.5.4 Flammable compressed gas shall be segregated from oxygen by a fire-resistive barrier (e.g., steel plating or concrete blocks) or by a distance of 6.1 m (20 ft).

7.1.5.5 Storage of flammable gases and oxygen shall be located outside buildings or in a room designed in accordance with NFPA 55.

7.1.5.6 All electrical equipment within an enclosed storage room containing flammable gases shall be Class I, Division 2, Group A, B, C, or D.

7.1.5.7 Outside storage areas shall be kept clear of dry vegetation and combustible materials for a minimum distance of 7.6 m (25 ft).

7.1.5.8 Storage areas shall be provided with physical protection from vehicle damage.

7.1.5.9* Compressed gas cylinders shall be clearly marked using the designations of the DOT.

7.1.5.10 Empty cylinders shall be clearly marked “Empty” or “MT” or stored in a separate area.

7.2 Liquid Propane Storage and Use. The storage, use, and handling of liquefied petroleum gases (LP-Gases), such as propane or butane, shall be in accordance with NFPA 58.

7.3 Flammable and Combustible Liquid Storage Tanks on the Surface.

7.3.1* Design and Location of Storage Tanks.

7.3.1.1 Storage tanks shall be built, installed, and used in accordance with NFPA 30.

7.3.1.2* The tank shall be listed for its use.

7.3.1.3 Aboveground flammable liquids storage tanks shall be located a minimum of 15.2 m (50 ft) from important structures.

7.3.1.4 Aboveground combustible liquid storage tanks shall not be stored closer than 1.5 m (5 ft) from important structures.

7.3.1.5 Aboveground tanks shall not be located within 30.5 m (100 ft) of mine openings, fan installations, hoist houses, or any buildings connected to these operations.

7.3.1.6 The contents of the storage tank shall be identified by the designations given in NFPA 704.

7.3.2* Control of Spillage from Aboveground Tanks. Facilities shall be provided so that any accidental discharge will be prevented from endangering important facilities or adjoining property or from reaching waterways.

7.3.3 Normal and Emergency Venting.

7.3.3.1 Atmospheric storage tanks shall be vented in accordance with API 2000, *Standard for Venting Atmospheric and Low-Pressure Storage Tanks*.

7.3.3.2 As an alternative to 7.3.3.1, the normal vent shall be at least as large as the largest filling or withdrawal connection, but in no case shall it be less than 31.7 mm (1¼ in.) nominal diameter.

7.3.3.3 Aboveground tanks storing flammable liquids shall have the vent normally closed and be equipped with a flame arrester.

7.3.3.4* Emergency Relief.

7.3.3.4.1 Emergency relief shall be provided for all aboveground tanks storing material with a flash point less than 93.3°C (200°F).

7.3.3.4.2 The relief shall be in the form of a relief valve or a weak roof-to-shell seam.

7.3.3.5 Tanks containing material with a flash point greater than 93.3°C (200°F) that are located in the same diked area as liquids with lower flash points shall also conform to 7.3.3.4.

7.3.3.6* Vent piping shall be located so that the discharge is above the fill pipe opening and at least 3.7 m (12 ft) above the adjacent ground level.

7.3.4 Fuel Lines.

7.3.4.1 Fuel lines shall be equipped with valves to cut off fuel at the source.

7.3.4.2 Fuel lines with flexible piping shall be equipped with a fusible link activated automatic shutoff valve located at the point where the fuel line exits the storage tank.

7.3.5 Leakage and Overfill of Buried Tanks.

7.3.5.1 Buried tanks with flammable liquids shall have a leak detection program in effect.

7.3.5.2 Accurate inventory records of buried tanks with flammable liquids shall be maintained.

7.3.5.3 Buried tanks shall be equipped with an overfill alarm interlocked to shut off the feed when the tank is 95 percent full and to alarm at 90 percent.

7.3.6 Vehicle Barriers. Vehicle barriers shall be provided around aboveground stationary storage tanks or fuel pumps that are located in an area subject to vehicular traffic.

7.3.7 Control of Ignition Sources.

7.3.7.1 Signs warning against smoking or open flames shall be posted so they can be readily seen.

7.3.7.2 Storage tanks containing flammable liquids shall be grounded.

7.3.7.3 Tank trucks with flammable liquids shall be grounded by being electrically bonded to the fill pipe when storage tank filling operations are taking place.

7.3.7.4 Areas surrounding storage tanks shall be kept free of grass, weeds, underbrush, or other combustible material such as trash or leaves for at least 7.6 m (25 ft) in all directions.

7.3.8 Fire Extinguishers. Two fully charged and operable 9.1 kg (20 lb) extinguishers with minimum ratings of 4-A:40-B:C shall be provided within 9.1 m (30 ft) of the tank or pump.

7.4 Flammable and Combustible Liquid Storage on Surface Equipment and in Buildings.

7.4.1 The storage, use, and handling of flammable and combustible liquids in surface buildings shall conform with NFPA 30, except Sections 18.4 and 21.8 and Chapters 1, 2, 3, 4, and 15.

7.4.2 Flammable and combustible liquids on equipment, except in fuel tanks on vehicles, shall be stored and handled in accordance with NFPA 30.

7.4.3 Flammable liquids of a quantity greater than 94.6 L (25 gal) shall be stored in a flammable liquids cabinet.

7.4.4 All flammable aerosols shall be stored in a flammable liquids cabinet.

7.4.5* On equipment, combustible liquid storage in drums or totes shall not exceed a 1-day supply.

7.4.6 Upon request, the mine operator shall provide the authority having jurisdiction with information regarding the composition and flash point of the flammable and combustible materials.

7.4.7 Smoking and Open Flames.

7.4.7.1 Smoking and open flames shall be prohibited in areas or locations where fire or explosion hazards exist.

7.4.7.2 Signs warning against smoking and open flames shall be posted.

7.4.8 Vehicle Refueling.

7.4.8.1 Vehicles using liquid fuels shall be refueled only at locations designated for that purpose and from approved dispensing pumps and nozzles.

7.4.8.2 Engines, except diesel engines, shall be shut off during refueling.

7.5 Flammable Liquids Stored and Used Underground.

7.5.1 General.

7.5.1.1* Electrical equipment in flammable liquid storage areas shall be classified as one of the following:

(1) Class I, Division 1 as specified in *NFPA 70*
(2) "Permissible" electrical equipment

7.5.1.2 Flammable liquids in storage shall be kept in closed containers.

7.5.1.3 Flammable liquids shall be permitted to be used only where there are no open flames or other sources of ignition within the possible path of vapor travel in flammable concentrations.

7.5.1.4 Flammable liquid containers shall be returned to a flammable liquid storage area after use.

7.5.1.5 All aerosol cans shall be treated as containing flammable liquids unless otherwise specifically identified.

7.5.1.6 Individual aerosol cans that are used regularly in normal operations shall be permitted on mobile equipment or in tool cabinets and shall be protected from mechanical damage.

7.5.2 Flammable Liquid Containers.

7.5.2.1 Flammable paints shall be stored only in original containers or cans of not over 19 L (5 gal) capacity.

7.5.2.2 All other flammable liquids shall be transferred to a listed safety can prior to being transported underground.

7.5.2.3 Safety cans containing Class IA flammable liquids shall not exceed 7.6 L (2 gal) capacity.

7.5.2.4 All flammable liquid containers shall be labeled with the word "Flammable."

7.5.2.5 Flammable liquid containers shall be stored in a stable manner.

7.5.3 Flammable Liquid Storage Areas.

7.5.3.1 Flammable liquids shall be stored in one of the following:

(1) Listed or approved noncombustible storage cabinets
(2) Cabinets meeting the requirements specified in Section 9.5 of NFPA 30
(3) An enclosure of fire-resistive construction

7.5.3.2 In operating areas, containers of flammable liquids and aerosol cans shall be stored at least 7.6 m (25 ft) away from potential ignition sources such as energized trolley wire, energized electrical equipment, and other operating equipment.

7.5.3.3 The aggregate quantity of flammable liquids, including aerosol cans, in a flammable liquid storage area shall not exceed 227 L (60 gal).

7.5.4 Dispensing Flammable Liquids.

7.5.4.1 Flammable liquids shall be drawn from or transferred into containers using only the following methods:

(1) From safety cans
(2) From a container by means of a device that draws through an opening in the top of the container
(3) By gravity through a listed or approved self-closing valve or self-closing faucet

7.5.4.2 Transferring flammable liquids by means of an electric pump or pressurizing a container with air shall be prohibited.

7.5.4.3 Transferring flammable liquids by pressure of inert gas shall be permitted only if controls, including pressure relief devices, are provided to limit the pressure so it cannot exceed the design pressure of the container.

7.5.4.4 At least one portable fire extinguisher having a nominal capacity of 9.1 kg (20 lb) with a minimum rating of 4-A:60-B:C shall be located not more than 9.1 m (30 ft) from any area where flammable liquid is dispensed.

7.6 Combustible Liquids Stored and Used Underground.

7.6.1 General.

7.6.1.1 This chapter shall not apply to combustible liquids in use, such as the following:

(1) Diesel fuel in the fuel tanks of diesel-powered vehicles
(2) Hydraulic fluid in the reservoirs of hydraulic equipment
(3) Lubricating oil in the lubrication reservoirs of operating equipment

7.6.1.2 Combustible liquids in approved tanks or containers meeting the following requirements shall be exempt from the requirements for storage areas:

(1) Class II combustible liquids stored in containers meeting the requirements of this chapter and not exceeding 227 L (60 gal)
(2) Class III combustible liquids stored in containers or approved tanks as specified in this chapter and not exceeding 2498 L (660 gal)

7.6.1.3 Combustible liquid containers shall be stored and shall be kept closed while stored in the following manner:

(1) Drums holding 208 L (55 gal) and 114 L (30 gal) shall be set vertically, unless seam height will not allow, and not over one drum high.
(2) Drums holding 60.6 L (16 gal) shall be set vertically and not over two drums high.
(3) Pails holding 19 L (5 gal) shall be set vertically and not over four pails high.
(4) Cartons holding grease cartridges shall not be stacked over three cartons high.

7.6.1.4 Ventilation shall be provided wherever combustible liquids are stored to prevent the accumulation of ignitible vapors.

7.6.2 Combustible Liquid Containers and Tanks.

7.6.2.1 Tanks for handling combustible liquids shall be substantially constructed and fitted with filler caps, vents, and discharge valves that are protected in the event of derailment or ribbing of the vehicle carrying the tanks.

7.6.2.2* Containers shall be acceptable to the authority having jurisdiction.

7.6.2.3 Containers larger than 19 L (5 gal) shall be provided with vacuum and pressure relief.

7.6.2.4 The capacity limitations for combustible liquids in containers and portable tanks shall be in accordance with the definitions for *container* and *portable tank* in Chapter 3.

7.6.2.5 Combustible liquid storage tanks intended for fixed installation and portable installations in accordance with NFPA 30 shall be of materials compatible with the liquid stored.

7.6.2.6 Atmospheric tanks shall be built in accordance with NFPA 30.

7.6.2.7 The operating pressure of storage tanks shall not exceed their design working pressure.

7.6.2.8 Low-pressure tanks shall be built in accordance with NFPA 30.

7.6.2.9 The operating pressure of the vessel shall not exceed the design working pressure.

7.6.2.10* Pressure vessels shall be built in accordance with NFPA 30.

7.6.2.11 Storage tanks shall be vented to prevent the development of vacuum or pressure from distorting the shell or roof of the tank as a result of filling or emptying and atmospheric temperature changes.

7.6.2.12 Protection shall also be provided to prevent overpressure from any filling source exceeding the design pressure of the tank.

7.6.2.13* Storage tank vents shall be at least as large as the filling or withdrawing lines but no less than 31.7 mm (1¼ in.) nominal inside diameter.

7.6.2.14 If more than one fill or withdraw line can be used simultaneously, the vent capacity shall be based on the maximum anticipated simultaneous flow.

7.6.2.15 Vent pipes shall be constructed to drain toward the tank without sags or traps to collect liquid.

7.6.2.16 Connections for all tank openings shall be liquidtight.

7.6.2.17 Each connection to a tank through which liquid normally can flow shall be provided with an external valve located at the shell of the tank.

7.6.2.18 Tanks containing combustible liquids shall be provided with a means for quick cutoff of flow in the event of fire in the vicinity of the tank.

7.6.2.19 Openings for manual gauging, if independent of the fill pipe, shall be kept closed when not gauging.

7.6.2.19.1 Each opening for any liquid shall be protected against liquid overflow and possible vapor release by means of a spring-loaded cap or other device.

7.6.2.19.2 Substitutes for manual gauging shall be permitted.

7.6.3* Transfer and Transport of Combustible Liquids.

7.6.3.1 Combustible liquid shall be permitted to be transferred into the mine by pipeline, portable tank, closed container, or safety can.

7.6.3.2 When combustible liquid is transferred into the mine, it shall be transported or transferred directly to the storage area or location where it will be used.

7.6.3.3 Combustible liquid shall not be transported in the same conveyance with personnel unless the items are secured or are small enough to be carried by hand without increasing the risk of an accident.

7.6.3.4 Combustible liquid containers or tanks loaded on rail or trackless vehicles shall be secured against shifting and damage during transit.

7.6.3.5 Rail or trackless vehicles that carry supplies for production areas in addition to combustible liquids shall have provisions for securing or separating those supplies from the lubricants and combustible liquids so that, in the event of derailment or ribbing, the supplies will not puncture containers or tanks.

7.6.3.6 Vehicles carrying combustible liquids shall be kept clean of accumulations of oil, grease, and other combustible material.

7.6.3.7 Spilled combustible liquids shall be cleaned up immediately.

7.6.3.8 Any remaining residue shall be covered with an oil absorbent or rock dust.

7.6.3.9 Combustible liquid containers or tanks shall be at least 305 mm (12 in.) below energized trolley wires or protected from contacting the wire by insulation while being transported by trolley wire–powered systems.

7.6.3.10* The quantity of combustible liquid in containers or tanks off-loaded from transport vehicles and stored in an operating area shall not exceed a 3-day supply for operations in that area.

7.6.3.11 A single tank or container with a capacity exceeding a 3-day supply shall be permitted.

7.6.3.12* Pipeline systems used for combustible liquid transfer shall be permitted to be either wet or dry pipe installations.

7.6.3.12.1 Piping, valves, and fittings used for combustible liquid transfer shall be designed for the expected working pressures and structural stresses as follows:

(1) Piping, valve, and fitting burst strengths shall be at least four times the static pressure.
(2) The pipeline shall be designed to withstand the mechanical and thermal stresses caused by exposure to fire.

7.6.3.12.2 A manual shutoff valve shall be installed in the pipeline at the surface storage tank and at the point of underground discharge.

7.6.3.12.3 An additional shutoff valve shall also be installed in each branch line where the branch line joins the main line.

7.6.3.12.4 The pipeline system shall be guarded and protected against physical damage.

7.6.3.12.5 Guarding by choice of location shall be considered an acceptable practice.

7.6.4 Temporary Areas for the Storage of Combustible Liquids in Portable Containers.

7.6.4.1 Portable combustible liquid storage areas shall meet one of the following criteria:

(1) They shall be located a minimum of 30.5 m (100 ft) from explosives magazines, electrical substations, shops, working faces, or other combustible liquid storage areas.
(2) They shall be separated from explosives magazines, electrical substations, shops, working faces, or other combustible liquid storage areas by unexcavated coal or rock or by a masonry bulkhead.

7.6.4.2 Unless equipped with an approved fire protection system, the storage area shall be a minimum of 30.5 m (100 ft) from any shaft station and 7.6 m (25 ft) from energized trolley wire.

7.6.4.3 A portable combustible liquid storage area shall be recessed or otherwise located and protected from accidental damage by mobile equipment or blasting.

7.6.4.4 The aggregate quantity of diesel fuel in a combustible liquid storage area for portable containers or tanks shall not exceed 1893 L (500 gal).

7.6.4.5 The aggregate quantity of Class II and Class III combustible liquids in a combustible liquid storage area for portable containers or tanks shall not exceed 3785 L (1000 gal).

7.6.5* Fixed Areas for Class II Liquid Storage.

7.6.5.1 Fixed combustible liquid storage areas shall be located as follows:

(1) A minimum of 30.5 m (100 ft) from explosives magazines, electrical substations, shaft stations, slope bottoms, and shops
(2) A minimum of 30.5 m (100 ft) from other flammable or combustible liquid storage areas or separated by one of the following:
    (a) Unexcavated coal
    (b) Rock
    (c) Masonry bulkhead with a minimum thickness of 102 mm (4 in.) of blocks or 51 mm (2 in.) of reinforced gunite
(3) A minimum of 30.5 m (100 ft) from any working face and out of the line of sight of blasting or a minimum of 152 m (500 ft) within line of sight from any working face to avoid damage from fly rock
(4) A minimum of 7.6 m (25 ft) from normally energized trolley wire

7.6.5.2 All fixed combustible liquid storage areas shall be enclosed and protected by an approved, fixed automatic fire suppression system.

7.6.5.2.1 All fixed combustible liquid storage area enclosures shall be of noncombustible construction, including floor, roof, roof supports, doors, and door frames.

7.6.5.2.2 Exposed coal within all fixed combustible liquid storage areas shall be covered with noncombustible materials such as gunite, shotcrete, or preformed masonry.

7.6.5.2.3 Bulkheads, if used, shall be sealed and be built of or covered with noncombustible materials.

7.6.5.2.4 All fixed combustible liquid storage area enclosures shall be constructed to provide suitable spill containment or shall be provided with a suitable floor drain to direct spilled liquid to a containment sump or vessel.

7.6.5.2.5 All openings to the storage area enclosures shall be sealed with fire-resistive stoppings.

7.6.5.2.6 The access opening through which containers are moved shall be located on the intake side.

7.6.5.2.7* All doors shall be of the self-closing type and shall be listed or approved and constructed of noncombustible materials.

7.6.5.2.8 A personnel door shall be provided on the side where air enters the enclosure.

7.6.5.2.9 The storage area enclosure shall be vented directly to the return or the surface.

7.6.5.2.10* Tanks shall rest 305 mm (12 in.) above the ground or on foundations made of concrete, masonry, piling, or steel.

7.6.5.2.11 Tank foundations shall be designed to prevent accumulation of combustible liquid under the tank, to minimize the possibility of uneven settling of the tank, and to minimize corrosion in any part of the tank resting on the foundation.

7.6.5.2.12 All piping, valves, and fittings shall be suitable for the expected working pressures and structural stresses.

7.6.5.2.13 Ventilation shall be provided to prevent the accumulation of ignitible vapors.

7.6.5.2.14 Empty or idle combustible pallet storage within the combustible liquid storage area shall not be permitted.

7.6.5.2.15 The aggregate quantity of Class II and Class III combustible liquids in a fixed combustible liquid storage area shall not exceed 18,927 L (5000 gal), of which Class II shall not exceed 3785 L (1000 gal).

7.6.6 Fixed Storage Areas for Class III Combustible Liquids. Class III combustible liquids shall be stored in fire-resistive containers within an enclosure of fire-resistant construction.

7.6.7 Storage, Transport, and Dispensing of Combustible Liquids Using Mobile Equipment.

7.6.7.1 Where combustible liquids are stored on mobile equipment such as mobile service trucks, the equipment shall be parked at a fixed location or a location that meets the requirements of 7.6.4 when not in use.

7.6.7.2 The aggregate quantity of combustible liquids carried on mobile equipment shall not exceed 3785 L (1000 gal).

7.6.7.3 Diesel fuel tank trucks shall not exceed 1893 L (500 gal) storage capacity.

7.6.8* Dispensing Combustible Liquids.

7.6.8.1 Class III combustible liquids shall be permitted to be dispensed through the application of positive pressure to containers or tanks only where the containers or tanks are certified as pressure vessels.

7.6.8.2 Class II combustible liquids shall not be dispensed using compressed gas.

7.6.8.3 Where electrically powered pumps are used to dispense combustible liquids, a switch or circuit breaker shall be provided at a location away from dispensing devices, including remote pumping systems, to shut off the power to all dispensing devices in an emergency.

7.6.8.4 Dispensing nozzles for Class II combustibles shall be of the self-closing type without a latch-open device.

7.6.8.5 At least one portable fully charged and operable fire extinguisher having a nominal capacity of 9.1 kg (20 lb) with a minimum rating of 4-A:60-B:C shall be located not more than 9.1 m (30 ft) from any area where combustible liquid is dispensed.

7.6.8.6 Dispensing Class II combustible liquid from containers or tanks shall be accomplished by an approved transfer pump or by gravity flow.

7.6.8.6.1 Where needed, containers or tanks shall be equipped with an approved vent.

7.6.8.6.2 If a manual valve is used, it shall be of the self-closing type without a latch-open device.

7.6.8.7 Spillage shall be cleaned up.

7.6.8.8 Remaining residue shall be covered with an oil absorbent or rock dust.

Chapter 8 Mine Surface Buildings

8.1 Construction.

8.1.1 This chapter shall include mine offices, bathhouses, warehouses, vehicle storage, shops, and permanent miscellaneous buildings.

8.1.2 Offices over 1394 m^2 (15,000 ft^2), warehouses over 929 m^2 (10,000 ft^2), and shops over 465 m^2 (5000 ft^2) shall be constructed of noncombustible materials or provided with an automatic sprinkler system installed in accordance with NFPA 13.

8.2 Fire Prevention.

8.2.1 No smoking shall be allowed in warehouses.

8.2.2 Combustible storage shall be maintained at least 0.9 m (3 ft) from electrical panels and electric resistance heaters.

8.2.3 Oily waste or rags that can create a fire hazard shall be placed in covered metal containers.

8.2.4 Battery rooms shall be in accordance with *NFPA 70*, Article 480.

8.2.4.1 Battery-charging installations shall be located in a designated area that is protected against damage from mobile equipment.

8.2.4.2 Each battery-charging installation shall be equipped with the following:

(1) Approved portable multipurpose fire extinguisher(s)
(2) Ventilation for the removal of generated gases from charging batteries
(3) A means for flushing spilled electrolyte

8.3 Life Safety.

8.3.1 Two means of egress shall be provided from multistory buildings.

8.3.2 For office, bathhouse, and warehouse areas, emergency lighting shall be provided in each stairwell or hallway that is the means of egress in accordance with NFPA *101*.

8.3.3 For office, bathhouse, and warehouse areas, emergency exit signs shall be provided along the means of egress.

8.4 Flammable and Combustible Liquids.

8.4.1 All storage and handling of flammable and combustible liquids shall conform to the guidelines established in NFPA 30.

8.4.2 The quantity of flammable liquids and aerosols stored outside a flammable liquids storage cabinet shall not exceed 94.6 L (25 gal).

8.4.3 Other than in shops, the quantity of combustible liquids outside a flammable liquids storage cabinet or room constructed in accordance with NFPA 30 shall not exceed 454 L (120 gal).

8.4.4 Dispensing of flammable or combustible liquids in warehouses shall be prohibited.

8.4.5 Storage of acetylene, oxygen, or other welding gases inside warehouses shall be prohibited.

8.4.6 Drip pans shall be provided to catch leakage or spillage wherever flammable or combustible liquids are dispensed.

8.4.7 Fusible link–actuated automatic closers shall be provided on all parts cleaning tanks.

8.5* Compressed Gas Storage and Usage. Storage and use of compressed gases in and around mine buildings shall be in accordance with Section 7.1.

8.6 Fire Detection and Protection.

8.6.1 For multistory office buildings, a central station or proprietary alarm system shall be installed in accordance with *NFPA 72*.

8.6.1.1 Alarms shall include smoke detectors, duct detectors, and manual pull stations.

8.6.1.2 In addition, if sprinklers are installed, water flow, valve tamper, and low building temperature alarms shall be provided.

8.6.1.3 All equipment shall be listed or approved for its intended use.

8.6.2* If sprinkler systems are installed, they shall be in accordance with NFPA 13.

8.6.3* If fire hydrants are installed, they shall be in accordance with NFPA 24.

8.6.4 If a building is more than two stories high, a standpipe system shall be installed in accordance with NFPA 14.

8.6.5 If a gaseous fire suppression system is installed in a computer or telephone equipment room, it shall be in accordance with NFPA 2001.

8.6.6* Fire extinguishers shall be provided and maintained in accordance with NFPA 10.

8.6.6.1 Fire extinguishers shall be inspected at least every 6 months.

8.7 Water Supplies. If sprinklers or fire hydrants are installed, water supplies shall be capable of providing the required flow rate and pressure necessary for the fire protection features for at least one hour.

Chapter 9 Coal Conveyance and Storage

9.1* Conveyors — General.

9.1.1* Belt conveyors shall meet the following minimum requirements:

(1) Belt alignment limit switches shall be provided on conveyors to shut down belts that are tracking improperly.
(2) Slip switches shall be provided to detect a slipping or jammed belt and shall be interlocked to shut off driving power when the belt stops or slows down by more than 20 percent of its normal speed.
(3) Slip switches shall be tested on an annual basis.
(4) Shutoff power shall be provided on contributing conveyors to prevent any operating conveyor from discharging material to a stopped downstream conveyor.
(5) Means shall be provided to remove tramp metal and other foreign objects as early in the handling process as possible.
(6) Hydraulic systems for belt alignment, if provided, shall use only listed fire-retardant hydraulic fluids or shall be protected by an automatic fire protection system.
(7) Alarms shall annunciate in the operator's control room.
(8) Electrical equipment shall be classified as Class II, Division 2, Group F in all areas where required by *NFPA 70*.
(9) Guarding for machinery in the drive area and at other points along the belt shall be made of noncombustible material.

9.1.2* Structures supporting belt conveyors shall be designed to prevent coal accumulations.

9.1.2.1 The design shall include any surface near the belting that can catch and retain fine coal liable to ignite spontaneously.

9.1.3 Consideration shall be given to the possibility of static electrical discharge at the conveyor head and tail pulleys located in dry climates where bituminous and lower ranking–type coals are handled.

9.1.3.1 Factors that shall be considered are belting materials, belt speed, and housekeeping of spilled coal dust.

9.1.3.2 Where such conditions as described in 9.1.3 exist, the use of static dissipators or eliminators shall be considered.

9.1.4 Attention shall be given to the prevention of and cleaning of accumulations of fine coal dust beneath and close to belt conveyors.

9.2 Overland Conveyors.

9.2.1 Chute plug alarms shall be provided for long runs of belt or critical conveyor systems.

9.2.2 The conveyor path shall be kept free of all grass, weeds, trash, or any other material that could create an exposure to the belt should it catch on fire.

9.2.3 Motor control center (MCC) buildings for conveyor systems shall be kept free of accumulations of coal dust.

9.3 Below-Grade Reclaim Conveyors.

9.3.1 Methane detection shall be provided in below-grade reclaim conveyor areas.

9.3.2 Equipment shall be interlocked to de-energize upon detection of a 2 percent concentration of methane.

9.3.3 Portable methane detectors are an acceptable alternative to fixed detectors, provided a reading is taken once per shift.

9.3.4 Hydraulic units more than 7.6 m (25 ft) inside the entrance and greater than 189 L (50 gal) total capacity shall have listed fire-resistive hydraulic fluid or shall be provided with an automatic fire suppression system. The fire suppression system shall be interlocked to shut down the hydraulic unit and send an alarm to a constantly attended location.

9.4 Underground Conveyors.

9.4.1 Underground conveyor belts shall be of a flame-resistant material and approved by the authority having jurisdiction.

9.4.2 Entries in which belt conveyors are installed shall be kept free of accumulations of coal and coal dust around the belt idlers, pulleys, and belt edges and shall be rock-dusted.

9.4.3* Fixed combustible material such as posts, cribbing, and roof supports shall be guarded from contact with the belt by the use of noncombustible material or by distance and shall be located at a distance of at least 152.4 mm (6 in.) from any idler or pulley.

9.4.4 Belt conveyor installations shall use a support structure without a deck between the upper and lower belt flights.

9.4.5 Belts that carry the load of the belt on a low-friction metal deck without rollers shall be permitted to be used.

9.4.6 Automatic Fire Suppression Systems at the Belt Drive.

9.4.6.1 Deluge water spray systems, foam systems, closed-head sprinkler systems, or dry-chemical systems automatically actuated by rise in temperature shall be installed at main and secondary belt conveyor drives.

9.4.6.1.1 If sprinkler or water systems are installed, they shall comply with 4.3.3.3 and 9.4.6.3 of this standard.

9.4.6.1.2 If dry chemical systems are installed, they shall be installed and maintained in accordance with NFPA 17 and the manufacturer's instructions.

9.4.6.2 Fire suppression systems shall extend to the drive areas of belt conveyors, including drive motor(s), reducer, head pulley, and belt storage unit (takeup), including any hydraulic power unit; its electrical controls; and the top and bottom of the first 15.2 m (50 ft) of belt from the drive on the downwind side.

9.4.6.2.1 Where a pre-engineered dry chemical fire suppression system is to be used, protection shall also be provided for the top surface of both the top and bottom belts, and the bottom surface of the top belt of the first 15.2 m (50 ft) of fire-resistant belt or 45.7 m (150 ft) of non-fire-resistant belt from the drive on the downward side.

9.4.6.3 Water-Based Fire Suppression Systems.

9.4.6.3.1 Water Supply.

9.4.6.3.1.1 The water supply shall be free of excessive sediment and corrosives. An approved strainer with a flush-out connection and manual shutoff valve shall be provided.

9.4.6.3.1.2 The water supply shall provide the required flow for not less than 60 minutes.

9.4.6.3.1.3* Approved or listed flexible connections shall be permitted from the water main to the pressure reducing device or shutoff valve to the sprinkler system.

(A) The flexible connection shall be rated at a pressure that exceeds the maximum water pressure expected on the system.

(B) If a non-metallic connection is used, it shall not be within 3.0 m (10 ft) of the belt drive motors or primary roller drive.

9.4.6.3.1.4 If a pressure regulator is used, it shall be set below the maximum pressure allowed by the pressure rating of the piping and fittings.

9.4.6.3.1.5 If a pressure regulator is used, it shall be inspected and tested on a weekly basis to ensure that it is functioning properly and the sprinkler system has the right amount of pressure.

9.4.6.3.2 General Sprinkler Requirements. Sprinkler systems shall meet the following requirements:

(1) The sprinklers shall be installed in accordance with NFPA 13 as far as practical, and shall have components that have been listed.
(2) The sprinkler head activation temperature shall not be less than 65.6°C (150°F) or greater than 148.9°C (300°F).
(3) Sprinklers shall be kept free of excessive rock dust, muck, conveyor string, or any other material that can block the discharge or insulate the fusible link.
(4) The application rate shall not be less than 10.2 L/min/m^2 (0.25 gpm/ft^2) of the top surface of the top belt, bottom surface of the top belt, and the top surface of the lower belt.
(5) With a water flow and pressure than is present under normal mine operating conditions, the residual pressure measured downstream of the opened sprinklers or the 8-head inspector's test connection of 70 kPa (10 psi) or greater for belt drive systems shall be maintained at all times.
(6) Maximum distance between nozzles on a branch line shall not exceed 2.4 m (8 ft).
(7) Piping for the deluge, foam, or closed-head sprinkler system shall be metal and listed for sprinkler applications.
(8)*Sprinkler piping shall be supported by UL-listed pipe hangers or other substantial metal supports such as angle iron, U bolts, or heavy chain.
(9) The system shall be interlocked to shut down the conveyor and provide an audible and a visual alarm.
(10) The components of the system shall be located so as to minimize the possibility of damage by roof fall or by the moving belt and its load.

9.4.6.3.3 Deluge Water Systems. Deluge water spray systems shall meet the requirements of 9.4.6.3.3.1 through 9.4.6.3.3.4.

9.4.6.3.3.1 The system shall be activated by heat detectors or no less effective means.

(A) Detectors shall be located at the belt drive, hydraulic takeup unit (unless fire-resistive fluid is used), discharge roller, and the roof above the conveyor.

(B) Detectors at the roof line should be spaced 2.4 m to 3.0 m (8 ft to 10 ft) apart along the entire length of the protected area of the belt.

9.4.6.3.3.2 The water spray nozzles shall be full cone, corrosion resistant [if less than 0.95 cm (⅜ in.) inside diameter or K-factor 4.2 or lower], and provided with blow-off dust covers.

9.4.6.3.3.3 If water spray sprinklers or open-head sprinklers are used, blow-off dust covers are not required to keep them clean as long as they are flow tested in accordance with 4.3.3.5.5.3.

9.4.6.3.3.4 A closed sprinkler head shall be used over the electrical controls.

9.4.6.3.4 Foam Systems.

9.4.6.3.4.1 Foam systems shall meet the requirements of 9.4.6.3.4.2 through 9.4.6.3.4.5.

9.4.6.3.4.2 The system shall be activated by heat detectors or no less effective means.

(A) Detectors shall be located at the belt drive, hydraulic takeup unit (unless fire-resistive fluid is used), discharge roller, and the roof above the conveyor.

(B) Detectors at the roof line should be spaced 2.4 m to 3.0 m (8 ft to 10 ft) apart along the entire length of the protected area of the belt.

9.4.6.3.4.3 The nozzles shall be full cone, corrosion resistant [if less than 0.95 cm (3⁄8 in.) inside diameter or K-factor 4.2 or lower], and provided with blow-off dust covers.

9.4.6.3.4.4 The system shall have a capacity to last 25 minutes.

9.4.6.3.4.5 A closed sprinkler head should be used over the electrical controls.

9.4.6.3.5 Maintenance and Testing. Fire suppression systems shall be maintained and tested in accordance with 4.3.3.5.

9.4.7 Manual Extinguishing.

9.4.7.1 Water lines shall be installed parallel to the entire length of belt conveyors and shall be equipped with fire taps with valves at 91.4 m (300 ft) intervals.

9.4.7.2 The threads on the hose taps shall be protected against dirt and rock grit that can prevent a quick connection.

9.4.7.3 The hose tap at the belt drive area shall be at least 15.2 m (50 ft) upwind of the belt drive.

9.4.7.4* At least 152.4 m (500 ft) of fire hose with fittings shall be stored at strategic locations along the conveyor belt, that is, at transfer points, drive areas, and tailpieces.

9.4.7.5 For each conveyor belt exceeding 610 m (2000 ft) in length, an additional cache of materials as specified in 9.4.7.4 shall be provided.

9.4.7.6 For mines using a track haulage system, the same criteria as those in Section 9.2 through 9.2.3 shall be met.

9.4.7.7 The following materials shall be stored within 91.4 m (300 ft) or 5 minutes of a belt drive:

(1) 152.4 m (500 ft) of fire hose or a high-expansion foam device and 61 m (200 ft) of hose
(2) Tools to open a stopping between the belt entry and the adjacent intake entry
(3) 109 kg (240 lb) of rock dust

9.4.7.8 Foam.

9.4.7.8.1 The foam generator shall produce foam sufficient to fill 30.5 m (100 ft) of belt haulageway in not more than 5 minutes.

9.4.7.8.2 A 1-hour supply of foam shall be kept on hand.

9.4.7.9 The entry containing the main water line and crosscuts containing water outlets shall be accessible.

9.4.7.10 Suitable communication lines to the surface shall be provided in the belt haulageway or adjacent entry.

9.4.7.11 A crew consisting of at least five members for each shift shall be trained in fire-fighting operations. Fire drills shall be held at intervals not exceeding 6 months.

9.4.7.12 Two 9.1 kg (20 lb) dry-chemical extinguishers shall be located at the drive areas.

9.4.8* A dust suppression water spray system actuated by a “conflow” switch or similar device shall be provided at the belt feeder.

9.4.9 Electrical equipment shall be permissible where required by the authority having jurisdiction.

9.5* Coal Storage — General. Coal bins, bunkers, and silos shall meet the following requirements:

(1) Storage durations shall be limited to prevent spontaneous combustion.
(2) Equipment shall be of noncombustible construction designed to minimize coal hang-up.
(3) Means shall be provided to remove burning, wet, or smoldering coal so it can be disposed of without producing an explosion or a fire.

9.5.1 Storage Bins.

9.5.1.1 All interior bins handling dusty material shall be vented in accordance with 6.2.2.

9.5.1.2 Storage bins for coal shall be located so that sources of heat not intended specifically to control the temperature of coal do not raise the temperature of the coal in the bin, causing spontaneous combustion materially.

9.5.2 Coal Silos.

9.5.2.1 Coal shall not be stored in silos and bunkers for long periods. If coal must be stored for a long period, air entrainment shall be prevented using the following methods:

(1) Covering the top of the stored coal with a binder material
(2) Inerting the stored coal with recommended inert gas

9.5.2.2 Areas in the storage (hideouts) that can allow pockets of coal to form, dry, and combust spontaneously shall be removed.

9.5.2.3 Storage silos shall be constructed of noncombustible material.

9.5.2.4 Electrical equipment shall be installed to meet the requirements of *NFPA 70* in effect at the time of installation.

9.5.2.5 If a dust collector is provided, it shall be equipped with explosion relief panels in accordance with NFPA 68. The dust collector shall be grounded and have antistatic, fire-resistant bags.

9.5.2.6 Wash-down hoses shall be provided at the bottom of the silo.

9.5.2.7 Dual high-level cutoff switches shall be provided for the silo. The feed conveyor shall be interlocked to shut down on the low–high indication.

9.5.2.8 The silo shall be maintained on a regular cleaning schedule to minimize the buildup of coal beneath the hopper and other areas inside the silo.

9.5.2.9 Deluge water spray systems, foam systems, closed-head sprinkler systems, or dry-chemical systems automatically actuated by rise in temperature shall be installed over the belt drive areas on top of a silo.

9.5.3 Stacker Tubes and Coal Storage Piles.

9.5.3.1 Coal piles shall be designed to minimize the entrainment of air.

9.5.3.1.1 Minimization shall be permitted by development of a compacted edge around the pile.

9.5.3.1.2 The edge described in 9.5.3.1.1 shall be sealed with binder to aid in sealing.

9.5.3.2 Hot spots or areas of spontaneous combustion shall be removed by digging.

9.5.3.3 The use of water for extinguishment shall be used at a minimum.

9.5.3.4 Active storage piles shall be worked to prevent dead pockets of coal, a potential source of spontaneous heating.

9.5.3.5 Coal piles shall not be located above heat sources, such as steam lines, or sources of air, such as manholes.

9.5.3.6 Coal placed in long-term storage shall be piled in layers, appropriately spread, and compacted prior to the addition of subsequent layers to reduce air movement and to minimize water infiltration into the pile.

9.5.3.7 Where possible, storage piles shall be arranged to allow access to the pile with earth-moving equipment in the event of developing hot spots or fire.

Chapter 10 Truck, Rail, and Barge Loadouts

10.1 Construction.

10.1.1 The loadout shall be constructed of noncombustible material.

10.1.2 Conveyor systems shall be in accordance with Section 9.1.

10.2 Fire Prevention.

10.2.1 No smoking shall be allowed in the loadout control room.

10.2.2* Loadout control rooms shall be designed, constructed, and maintained to reduce the chances of coal dust entering the room.

10.2.3 Combustible storage shall be maintained at least 0.9 m (3 ft) from all electrical panels, gas-fired heaters, and electric resistance heaters.

10.2.4 Trash and other unnecessary combustibles shall not be allowed to accumulate in the loadout control room.

10.2.5 Motor control centers shall be thermographically scanned on an annual basis to identify hot spots and loose electrical connections.

10.2.6 Hydraulic equipment shall have the following alarms interlocked to shut down the equipment:

(1) Low oil pressure
(2) High oil temperature
(3) Low oil level

10.3 Life Safety.

10.3.1 Two means of egress shall be provided from the loadout control room if the room is more than two levels high.

10.3.2 For multistory buildings, emergency lighting shall be provided in accordance with NFPA *101*.

10.3.3 For multistory buildings, emergency exit signs shall be provided along the means of egress.

10.4 Fire Detection and Protection.

10.4.1 A smoke detector system shall be installed in the loadout control room in accordance with *NFPA 72*.

10.4.1.1 The smoke detector system shall actuate an audible and visual alarm system.

10.4.1.2 For infrequently occupied or remote locations, the system shall send an alarm to a constantly attended location.

10.4.2* A gaseous fire suppression system shall be installed in loadout control rooms that are not regularly occupied and located in remote areas.

10.4.3 An automatic fire suppression system shall be installed to protect hydraulic pumps that have a capacity over 189.3 L (50 gal) and are located on an upper floor.

10.4.3.1 The system shall be actuated by a heat detector system.

10.4.3.2 The system shall be interlocked to shut off the power to the unit.

10.4.3.3 A listed fire-resistive fluid shall be an acceptable alternative to an automatic fire suppression system.

10.5 Manual Fire Fighting.

10.5.1* Fire extinguishers shall be provided in accordance with NFPA 10.

10.5.2 For multistory buildings, an emergency response plan shall be developed with the input of the local fire department.

10.5.3 For areas subject to flood, an emergency response plan shall be developed to include fire-fighting procedures during a flood.

Chapter 11 Emergency Response, Manual Fire Fighting, and Training

11.1* Emergency Procedures.

11.1.1 Emergency procedures shall be provided to instruct all miners in the location and use of fire-fighting equipment, location of escapeways and exits, and evacuation procedures.

11.1.2 The emergency procedures shall include a specific fire-fighting and evacuation plan with procedures for evacuation of all miners not required for fire-fighting activities, rapid assembly and transportation of personnel and equipment to the fire scene, and operation of the fire suppression equipment available at the mine.

11.1.3 Instruction in emergency procedures shall be provided to all miners on an annual basis.

11.1.4 Instruction in the location of fire-fighting equipment, location of escapeways and exits, and evacuation procedures shall be provided to all miners prior to entering an active mining area for the first time.

11.1.5 All employees shall receive annual instruction on emergency evacuation procedures.

11.1.6 All employees shall receive annual instruction on the procedures for discharging portable fire extinguishers and the proper method of fire attack.

11.1.7 For underground mines, the following additional criteria shall be met:

(1) Fire drills shall be held on a 90-day basis. A record of the drill shall be kept and include the date, the number of

persons participating, the area of the mine involved, the procedures followed, and the equipment used.
(2) At least two miners in each working section on each production shift shall be proficient in the use of all fire suppression equipment in that section and know the location of the equipment.
(3) Visitors shall be trained on the hazards they might encounter and in the appropriate emergency procedures.

11.1.8 The local fire department shall be requested or invited to make an annual tour of the surface area of the mine buildings. The tour shall include all surface buildings, major equipment, the location of flammable and combustible liquid storage, a discussion of the water supply availability, and the location of electrical shutoffs.

11.2 Underground Operations.

11.2.1 General.

11.2.1.1 An emergency response team shall be available and trained in basic fire-fighting techniques that would include, but not be limited to, fire hose, foam generators, fire extinguishers, and smoke control.

11.2.1.2 Each operator of attended equipment and each miner assigned to job duties normally in sight of the equipment shall be proficient in the use of the fire suppression devices on that equipment.

11.2.1.3 On a maintenance shift, the foreman and at least one miner for every five shall be proficient in the use of fire suppression equipment available in the mine and know the location of the equipment.

11.2.2 Fire-Fighting Team. Mines shall have a fire-fighting team trained in basic fire-fighting techniques, for example, hose streams and foam generation.

11.2.2.1 The fire-fighting team shall have at least 16 hours of refresher training per year.

11.2.2.2 The team shall consist of at least five members on each shift.

11.2.2.3 Self-contained breathing apparatus (SCBA) and fire-retardant coats, boots, and gloves shall be provided for the fire-fighting team.

11.2.3 Emergency Vehicle.

11.2.3.1 All mines shall be provided with an emergency vehicle outfitted with fire hose, appropriate fittings, a "Y" or a "siamese" connection, two adjustable fire department–quality fog nozzles, various tools, and pressure regulators (where necessary).

11.2.3.2 If an underground water car is provided, it shall be at least 3785 L (1000 gal) capacity and shall have at least 91.4 m (300 ft) of fire hose with nozzles.

11.2.3.2.1 A water car shall be capable of providing flow through a hose of 190 L/min (50 gpm) at a nozzle pressure of 345 kPa (50 psi).

11.2.3.2.2 A portable dry-chemical car shall be permitted to be provided as long as it carries the extinguishing capacity equivalent to a water car.

11.2.3.2.3 The dry-chemical car described in 11.2.3.2.2 shall be no farther than 3.2 km (2 mi) from each working section.

11.2.4 Foam Generator. A high-expansion foam generator shall be available within 60 minutes of fire notification and have enough foam to supply the fire-fighting operation for 35 minutes.

11.2.5 Fire Hose and Hydrants.

11.2.5.1* Water lines installed parallel to haulage tracks using mechanized equipment in the track or adjacent entry shall be equipped with outlet valves at intervals of not more than 152.4 m (500 ft), and with 152.4 m (500 ft) of fire hose with fittings suitable for connection shall be provided at strategic locations.

11.2.5.2 Hydrants shall be provided along belt conveyors at intervals not to exceed 91.4 m (300 ft).

11.2.5.3 At least 152.4 m (500 ft) of fire hose shall be provided for each belt flight and strategically positioned within that belt flight.

11.2.5.4 The threads on the hose and hydrants shall be protected against dirt and rock grit.

11.2.5.5* Multiple hydrant assemblies, with the tools needed for their installation, shall be provided as part of each cache of emergency materials.

11.2.5.6 Fire hose shall be lined with a material having flame-resistant qualities meeting requirements for hose in the U.S. Bureau of Mines' Schedule 2G.

11.2.5.6.1 The covers of the fire hose shall be polyester or other material with flame-spread qualities and mildew resistance equal or superior to polyester.

11.2.5.6.2 The bursting pressure shall be at least four times the water pressure at the valve to the hose inlet with the valve closed.

11.2.5.6.3 The maximum water pressure in the hose nozzle shall not exceed a gauge pressure of 689.5 kPa (100 psi).

11.2.6 Emergency Materials. In addition to specific area equipment, the following equipment shall be readily available at locations not exceeding 3.2 km (2 mi) from each working section:

(1) 304.8 m (1000 ft) of brattice boards
(2) Two rolls of brattice cloth
(3) Two hand saws
(4) 11.3 kg (25 lb) of 8d nails
(5) 11.3 kg (25 lb) of 10d nails
(6) 11.3 kg (25 lb) of 16d nails
(7) Three claw hammers
(8) 25 bags of wood fiber plaster or 10 bags of cement (or equivalent material)
(9) 4536 kg (5 tons) of rock dust

11.3 Surface Operations.

11.3.1* Surface mines shall meet the same requirements for fire-fighting teams listed in 11.2.2 unless public fire fighters are available within 30 minutes with the capability to fight the most difficult fire at the mine site.

11.3.2 Fire extinguishers shall be provided in accordance with NFPA 10.

11.3.3 If fire hydrants are provided, they shall be installed in accordance with NFPA 24.

11.3.4 If fire hydrants are not provided, water trucks shall be the fire-fighting water source.

11.3.4.1 Water trucks shall be equipped with a pump, fire hose, nozzles, and appropriate fittings.

11.3.4.2 The water truck shall be equipped with a water cannon (turret).

11.3.4.3 The water truck shall be equipped with a connection to enable the fire department to take suction from the tank.

11.3.5 Fire hose and couplings shall be listed or approved. Cotton- or cotton-polyester-jacketed hose shall be treated in accordance with the U.S. Department of Agriculture Forest Service Specification 182 for mildew resistance.

11.3.6 Water lines shall be capable of delivering at least 378.5 L/min (100 gpm) at a hose nozzle pressure of 689.5 kPa (100 psi).

11.3.7 The water pressure at the hose nozzle shall not be excessively high so as to present a hazard to the hose operator.

11.3.8 The hose connections shall have threads compatible with the local fire department's hoses, or a supply of adapters shall be available to adapt the hose connections to the fire department hoses. The local fire department shall be consulted to ensure thread compatibility for hose connections.

Annex A Explanatory Material

Annex A is not a part of the requirements of this NFPA document but is included for informational purposes only. This annex contains explanatory material, numbered to correspond with the applicable text paragraphs.

A.1.1.1 In the development of this document, the data in NIOSH Information Circular 9470, "Analysis of Mine Fires for All Underground and Surface Coal Mining Categories: 1990–1999," were examined. Table A.1.1.1 shows the number of fires for underground coal mines, surface fires at underground coal mines, at surface coal mines, and at coal preparation plants, as well as the number of fire injuries and coal production for the time period from 1990 to 1999.

Analysis of the data shows a general decrease in the number of fires over the 10-year period, particularly from 1996 to 1999, while coal production increased slightly. The largest number of fires over the 10-year period, as well as for each 2-year time period, occurred at surface coal mines. There were 164 injuries due to fire during the 10-year period, with the number decreasing significantly over the last 4 years. There were two fatalities in 1991.

A.1.3 Because of the uniqueness of coal mining, provisions in this standard can differ from commonly accepted fire protection standards and guides for other types of occupancies.

A.3.2.1 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

A.3.2.2 Authority Having Jurisdiction (AHJ). The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

Table A.1.1.1 Number of Coal Mine and Preparation Plant Fires, Injuries Due to Fire, and Coal Production from 1990 to 1999

	Number of Fires*					
Years	Underground Coal Mines	Surface at Underground Coal Mines	Surface Coal Mines	Coal Preparation Plants	Number of Fire Injuries*	Coal Production† (10^6 short tons)
1990–1991	25	17	67	23	59	2,004
1992–1993	18	14	37	22	29	1,928
1994–1995	23	16	47	18	39	2,059
1996–1997	6	7	40	8	19	2,155
1998–1999	15	11	24	20	18	2,218
1990–1999 Total	87	65	215	91	164	10,364

†Derived from MSHA "Injury Experience in Coal Mining" publications.

A.3.2.4 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A.3.3.33 Mobile Equipment. Mobile equipment includes, but is not limited to, wheeled, skid-mounted, track-mounted, or rail-mounted equipment capable of moving or being moved.

A.4.2 Potential sources of ignition include, but are not limited to, the following:

(1) Smoking
(2) Open flames
(3) Cutting and welding
(4) Hot surfaces
(5) Frictional heat
(6) Static, electrical, and mechanical sparks
(7) Spontaneous ignition, including heat-producing chemical reactions
(8) Radiant heat

A.4.2.5.1 Automatic-closing doors provide a higher level of fire protection and are therefore recommended.

A.4.2.6 Belt fires originating away from the drive area usually have been caused by idlers with defective or stuck bearings. Tests have shown that such idlers can become moderately hot [93.3°C to 149°C (200°F to 300°F)]. The coal task group has been unable to find reliable evidence that idlers can become hot enough to ignite fire-retardant belting directly.

It appears that a warm or hot idler can cause fine coal dust accumulated around the idler to ignite. Then, when the belt has been stopped, coal burning beneath the belt ignites the belting.

The key to avoiding belt fires is to prevent the accumulation of fine coal dust around idlers. If a metal deck is provided between the carrying strand and the return strand of the belt, coal dust accumulates around the troughing idlers. Where possible, return idlers should be supported at a substantial height above the bottom so that coal dust is not likely to build up around return idlers. With proper clearance beneath these idlers, accumulations of coal dust can be cleaned up more easily.

Slat-type, self-cleaning tail pulleys are recommended. Coal dust discharged by such pulleys should be cleaned up frequently. Both good maintenance and good fire prevention necessitate that noisy bearings, which might indicate probable failure, be changed promptly before they become hot.

Conveyor belt fires have been caused by belts that lose proper alignment, with the edge of the moving belt then contacting combustible material. Loss of alignment can result from a number of factors, including displacement of idlers or pulleys and movement of supporting structure, spillage of conveyed material, and failure of a bearing (typically on a pulley). Where alignment is affected significantly, the edge of the belt can rub abrasively on the structure and objects near the edge of the belt. If the object on which the belt rubs is metal, the metal can become worn and heated. The edge of the belt can be damaged extensively, but the belt probably will not ignite because a point on the edge of the moving belt is in contact with the metal for only a very short period and will cool before it returns to the point of contact. The metal can become quite warm, but because it is a good conductor of heat, it will not become hot enough to ignite the belt if the belt stops. Nevertheless, if the material contacted is wood or another combustible, the combustible material could be heated by the friction of the edge of the moving belt until it ignites. Keeping combustible material away from the edge of the belt and use of alignment switches should prevent such fires.

A.4.2.11 Spontaneous combustion potential of coal depends on a number of factors, including mining practices, mining conditions, geology, and reactivity of the coal. The contributions of these factors can be determined by using a number of methods, including a NIOSH computer program named SPONCOM, which is available from the NIOSH web page.

A.4.2.11.2 Means to reduce the risk of spontaneous combustion include but are not limited to monitoring and trending of combustible gases, sealing, inerting, and using ventilation controls.

A.4.3 For further information see NIOSH Information Circular 9452, *An Underground Coal Mine Fire Preparedness and Response Checklist: The Instrument.*

A.4.3.1.1.1 Routing of water lines has caused severe problems in fighting fires at some large mines. These mines had multiple intake shafts spaced apart at considerable distances. Such ventilation can create a neutral point between the shafts, with fresh air moving from each shaft toward the neutral point. At the original opening of one mine, a water source was established and the water line was extended as the mining developed farther away from the original opening. With the water line extended to each new intake shaft and passing through each neutral point, a condition of opposite direction of flow of air and water existed beyond each neutral point.

If a fire occurs in an area of opposite flow, the fire has to be approached in the same direction as the airflow, but the water flow is moving through the fire area. Usually water lines in a fire area are damaged or broken by falling sections of burning roof. When a water line breaks in such a situation, the fire fighters are without water, and direct fire fighting is no longer possible. The fire then can be controlled only by sealing. At least one large coal mining company now provides an additional water source at each new intake shaft to ensure the ability to fight such fires.

The likelihood of this problem appears to be increasing as more mines are ventilating belt entries with air moving outby, while the water flow is inby. In some cases, mine management has recognized the problem and has developed procedures to change the direction of airflow in the event of a fire. Reversing the airflow should be done at a point close to and outby the fire to avoid pushing smoke-laden air back onto the fire. After the belt entry outby the fire has been cleared of smoke, the airflow can be reversed for the full length of the entry if desired.

Mines that obtain their water supply from an underground source also can have this problem of opposite directions of air flow and water flow. Usually there is no sure solution except to provide an alternative source of water or a large storage of water on the surface. If the power for the pumps is fed from the high-voltage system that feeds the mine and the fire damages the high-voltage cable anywhere on the system, the power can trip the entire system and shut down the pumps. Coordination of the electrical protective equipment or even a separate power supply might be needed to ensure that the pumps continue to supply water for fire fighting.

Even in situations where air and water are flowing in the same direction, management must recognize that water lines or hydrants in a burning entry are likely to be broken by the falling sections of burning roof. In such situations, a planned shutdown of the water line should be undertaken as soon as possible so a multiple hydrant can be installed in the water line at a convenient location close to the fire. With the multiple hydrant in place, at least three fire hose can be served effectively from the water line.

Because of the many factors that should guide the choice of location of water lines and hydrants, management should be properly qualified to select these locations, but management also should be able to justify its choice. Reliability of the water supply and ability of fire hose streams to reach a fire at any location or entry served by the water line should be the criteria by which the location is chosen.

A.4.3.1.1.9 Shutoff valve intervals of 305 m (1000 ft) are recommended. Indicator-type shutoff valves with labels specifying the normal operating position are recommended.

A.4.3.1.2.1 Water distribution lines generally cannot meet the capacity requirements of 4.3.1.2.1 unless 127 mm (5 in.) or 152.4 mm (6 in.) pipe is used for main water lines and 101.6 mm (4 in.) pipe is used for branch lines to producing areas. Higher nozzle pressures are recommended.

A.4.3.1.2.2 The required hose stream water demand equals a minimum supply of 817,650 L (216,000 gal).

A.4.3.1.3.1 Hydrants in a coal mine normally are only a valve screwed onto a tee that is installed on the water line. For the female coupling of a fire hose to be connected to a male thread, a pipe nipple usually is screwed into the discharge side of the valve. Because the threads of steel pipe nipples generally corrode if left exposed, brass nipples often are used instead of steel nipples. Many mines have begun to use Schedule 80 plastic nipples instead of steel. Regardless of the nipple material, the threads of the nipple should be protected against physical damage.

A properly designed system of hydrants and fire hose should make a good connection of fire hose lines to the hydrants without the need for tools.

The choice of locations for hydrants should be made to ensure that fire hose lines can be laid quickly from hydrants located on the water line through crosscuts to a fire located in any parallel entry or crosscut, rather than to provide convenience for use in the entry where the water line is located.

A.4.3.1.3.2 Hydrants should preferably be located in crosscuts, and stoppings in such crosscuts should be fitted with a man door.

A.4.3.2 Automatic detection systems and automatic sprinkler systems in mining facilities need to be specifically addressed for the following reasons:

(1) The contents of a mine occupancy are continually changing. Most items are not fixed and are designed to be moved with the mining operation. A mine operates as a heavy-duty excavation construction site and, thus, has the same transitory nature as a construction site.
(2) Unlike aboveground industrial occupancies, great distances are not unusual within an underground mine. Mines covering 64.75 km^2 (25 mi^2) or more are common.
(3) Mines have extremely harsh and unusual environments compared to aboveground industrial occupancies. Heavy concentrations of combustible dusts, the presence of explosive gases, temperature extremes, saturated humidity conditions, standing water, unstable strata, roof-to-floor heights that vary from 710 mm to 6.1 m (28 in. to 20 ft), and complex ventilation systems are all commonplace. The possibility of abuse from heavy machinery is a common hazard.
(4) Mining occupancies exhibit unique physical characteristics not found in any other type of occupancy. One example is the extreme pressures that can occur in a water line.
(5) Mines employ specialized facilities, equipment, and production processes not utilized in other industries. Fire protection efforts that fail to consider the unusual operating characteristics and fire protection requirements of underground coal mining systems could result in nonoptimal protection or the inadvertent introduction of hazards.

30 CFR 75.1103-4 provides requirements for installing fire detection systems in underground coal mines in the United States.

A.4.3.2.1.1 An automatic fire detector is a device designed to detect the presence of fire and initiate action. For the purpose of this standard, automatic fire detectors are classified as follows:

(1) *Heat detector*: a device that detects an abnormally high temperature or rate of temperature rise
(2) *Smoke detector*: a device that detects the visible or invisible particles of combustion
(3) *Flame detector*: a device that detects the infrared, ultraviolet, or visible radiation produced by a fire
(4) *Fire-gas detector*: a device that detects gases produced by a fire
(5) *Other fire detectors*: devices that detect a phenomenon other than heat, smoke, flame, or gases produced by a fire

Fire detectors should be installed as follows:

(1) *Vertical Placement.* Because the hot gases from a fire will rise owing to buoyancy forces, combustion products initially will be stratified near the roof of an entry. As the stratified gas layer moves away from the fire, the resultant cooling and dilution eventually will produce a well-mixed flow of combustion products. Data from full-scale fires indicate that some degree of stratification can exist at distances of hundreds of feet from the source of the fire.

    Because of this effect, fire detectors should be located at a vertical distance from the entry roof that does not exceed 25 percent of the average entry height. For example, in an entry with a height of 1.8 m (6 ft), the maximum distance from the roof at which a sensor should be located is 0.5 m (1½ ft). The maximum distance refers to the location of the actual sampling intake of the detector used.
(2) *Lateral Placement.* In general, the point of origin of a fire is unpredictable. It can occur along the floor, ribs, or roof of the entry. To provide optimum protection, it is recommended that the fire detectors be located within 0.6 m (2 ft) of the approximate midpoint of the entry.

    For entries in which the point of origin of the fire can be better estimated (such as a belt entry), the detectors should be located in such a manner that they provide for the estimated best coverage of that entry.

A.4.3.2.1.3 Batteries charged by the mine power system should indicate the condition of the batteries upon either manual or automatic activation of a battery check circuit.

For further information see *NFPA 72*.

A.4.3.2.1.4 Electrical equipment classified as "permissible" or "intrinsically safe" is certified as meeting the requirements of 30 CFR, Part 18, Chapter 1.

A.4.3.2.2.1 Based on U.S. Bureau of Mines Report of Investigation 9570, "Hazards of Conveyor Belt Fires," CO and smoke detectors provide a significant improvement over point type heat detectors in warning of a potential fire on conveyor belts.

A.4.3.2.2.2 U.S. Bureau of Mines Report of Investigation 9380, "Fire Detection for Conveyor Belt Entries," provides information on smoke and CO sensor alarm levels and sensor spacing as a function of belt entry cross-sectional area and belt entry air velocity.

A.4.3.3.1.1(3) Depending on the size of the equipment, additional manual actuators could be needed to provide quick access for activation of the system.

A.4.3.3.1.1(4) For further information on flame resistance, see 30 CFR 18.65.

A.4.3.3.1.1(6) Open-head deluge and water spray systems can be kept free of blockage by regular flow of water through the system. For example, fire suppression on continuous miners can be flowed once per shift to keep the nozzles clean. Deluge water spray systems at belt drives can be flowed weekly to keep the nozzles clean.

A.4.3.3.1.4 For criteria of equivalent protection, see 30 CFR 75.1107-13.

A.4.3.3.2.1 Wet-pipe automatic sprinkler systems have been found to be the preferred fire suppression systems for underground coal mines for the following reasons:

(1) They are the simplest systems available.
(2) They are the most reliable systems available.
(3) They provide selective operation, because only sprinklers close to the fire operate.
(4) They have the best performance record, especially on fires of Class A materials and of Class IIIB combustible liquids.
(5) They need minimal maintenance.
(6) They are nonelectrical.
(7) They use a limited quantity of water.
(8) The initial investment is low.

The major problem associated with automatic sprinkler systems in underground coal mines is the possibility of exposure to freezing conditions during cold weather. Another problem that can exist in very deep mines is that some of the listed components for automatic sprinkler systems might be unable to withstand the very high water pressure encountered (see U.S. Bureau of Mines Report of Investigation 9451, "Effect of Pressure on Leakage of Automatic Sprinklers"). It is not uncommon to encounter pressures above a gauge pressure of 3448 kPa (500 psi). The committee recommends testing sprinkler system components under anticipated maximum pressures. If sprinkler components are found to be unable to withstand the maximum pressure of the water line, the use of pressure regulators might be necessary. Experience has shown that pressure regulators can require considerable maintenance. Also, if the pressure regulating valve should leak, it might be necessary to provide a small relief valve on the discharge side of the regulating valve to prevent overpressure.

A.4.3.3.2.1(1) Under Report No. H0122086, "Suppression of Fires on Underground Coal Mine Conveyor Belts," the Department of the Interior, U.S. Bureau of Mines (USBM), conducted a series of full-scale fire tests.

The tests demonstrated that standard, 12.7 mm (½ in.) orifice, nominal 100°C (212°F) automatic sprinklers, located over the belt on 3 m (10 ft) centers, effectively controlled every test fire while opening only two sprinklers, with residual pressure held to a constant a gauge pressure of 69 kPa (10 psi).

From the time that the USBM tests were conducted, underground belts have tended to become wider to carry increased tonnage; therefore, belt fire suppression systems should be designed to supply more sprinklers than indicated by these tests. Because many conveyor belts stretch a long distance in a straight line, a fire scenario would involve only a portion of the belt, regardless of the overall length of the belt. Because the actual incidence of belt fires is low in underground coal mines, and most of those are in the area of the belt drive and the belt takeup, protection of only the area from the discharge pulley to the end of the takeup is needed. If the belt structure contains a deck between upper and lower strands of the belt, automatic sprinklers should be located beneath the deck, virtually doubling the size of the sprinkler system.

If the sprinkler system is extended to cover a distance greater than 30.5 m (100 ft) in one direction from the point where the pipe holding the automatic sprinklers along the roof is fed, then a hydraulic calculation of the system is recommended. Long runs of pipe should be flow tested as required by 4.3.3.5.5.1, with the eight open sprinklers installed at the distant end of the pipe run. Branch piping intended to protect limited areas should be piped with adequately sized pipe to carry the required water flow. Table A.4.3.3.2.1(1) should be used to determine the minimum size of pipe.

Larger systems should be separately flow tested as required by 4.3.3.5.5.1.

Table A.4.3.3.2.1(1) Minimum Pipe Sizes per Number of Sprinklers

Pipe Size	Maximum Number of Sprinklers on Pipe
1 in.	2
1¼ in.	3
1½ in.	5
2 in	10
2½ in.	20
3 in.	40
3½ in.	65
4 in.	100

For SI units, 1 in. = 25.4 mm.

A.4.3.3.2.2 Because many air compressors are moved frequently, the fire suppression system needs to be equally portable. Some compressors that have a deck or lid over the compressor have been fitted with piping and sprinklers attached to the underside of the deck. Other compressors without a deck have suitable piping with at least two sprinklers 3 m (10 ft) apart. The piping is made to be attached to roof bolts or otherwise suitably supported over the centerline of the compressor. The piping needs to be equipped with a pressure switch that prevents the operation of the compressor unless the piping is under pressure and with a flow switch that shuts the compressor down if water flows. If a fire hose is used to connect the piping to a water line, the connection point of the hose to the sprinkler piping should be located so that a fire on the compressor will not damage the fire hose.

A.4.3.3.3.1 NFPA 13 requires a minimum 140 kPa (20 psi) residual pressure for ordinary hazard pipe schedule sprinkler systems.

A.4.3.3.3.2.1 Pipe and fittings that permit limited motion of the pipe are recommended, as they allow the pipe to be held closer to the roof. If threaded fittings are used, steel pipe with extra-strength threaded fittings is recommended. Copper, aluminum, or other approved materials could be permitted if they are adequate for the pressure.

A number of mines use aluminum pipe or tubing with groove-type couplings and fittings. Where water pressure does not exceed 3448 kPa (500 psi), grooved couplings that have a 12.7 mm (½ in.) female national pipe thread (FNPT) outlet are used to provide connections for sprinklers. Piping put together in this manner can be located closer to an undulating roof, especially if the pipe lengths are short enough to put the couplings (and the automatic sprinklers) on 3 m (10 ft) centers. Mines that use groove-type couplings can have most of the piping precut and grooved in the shop, which simplifies installation underground. Rolled grooves are recommended because they do not reduce the strength of the pipe as much as the cut grooves do. If cut grooves are used, Schedule 40 or heavier pipe should be used.

A.4.3.3.3.2.5 Some automatic sprinklers might not withstand the water pressure that can be encountered in deep mines. Information on the effect of high water pressure on automatic sprinklers can be found in U.S. Bureau of Mines Report of Investigation 9451, "Effect of Pressure on Leakage of Automatic Sprinklers."

Under U.S. Bureau of Mines Report of Investigation 9538, "Performance of Automatic Sprinkler Systems for Extinguishing Incipient and Propagating Conveyor Belt Fires Under Ventilated Conditions," NIOSH conducted a series of full-scale fire tests under ventilated conditions of 1.1 and 4.0 m/s (225 and 800 ft/min) for fires up to 10.8 MW. The tests demonstrated that pendent and horizontal sidewall types were both able to extinguish incipient belt fires. Directional sprinklers showed a slightly improved performance in terms of maximum heat release rate at the lower airflow. Both pendent and horizontal sidewall sprinkler types were able to extinguish propagating fires. Horizontal sidewall sprinklers showed an increased effectiveness compared to the pendent sprinklers because of the increased upstream coverage area of the water discharge in terms of maximum heat release rate.

A.4.3.3.3.2.6 The restrictions on sprinkler spacing apply to sprinklers on the same line and those located between sprinklers on adjacent lines.

A.4.3.3.3.2.7 Where sprinkler positioning is such that full coverage can be impaired, such as where a single line of sprinklers protects a belt conveyor with little clearance, a flow test should be conducted to determine if adequate wetting of surface areas is achieved. Additional sprinklers should be provided in the event that adequate coverage is not achieved, or alternative arrangements such as rotated lines or sidewall sprinklers should be considered. Consideration also should be given to the need for noncombustible baffles to protect sprinklers from the discharge of adjacent sprinklers located within 1.8 m (6 ft).

A.4.3.3.3.5 Dry-pipe automatic sprinkler systems are more complex and more difficult to design and install than wet-pipe systems. The committee recommends that all systems be designed and installed by skilled and experienced personnel.

A pressure relief valve, set to relieve at a pressure below the maximum pressure rating of the dry-pipe valve, should be installed between the pressure regulating valve and the dry-pipe valve. The reclosing pressure of the relief valve should be higher than the set pressure of the regulating valve.

A.4.3.3.3.6.1 Underground shaft mines that use diesel-powered equipment generally employ underground diesel fuel storage areas to facilitate equipment refueling. Adit-type mines in the western United States might initially locate diesel fuel storage and refueling facilities on the surface; however, as the active mine workings progress farther from the adit portal(s), these facilities will likely be moved underground.

A common means of fire protection in many underground diesel fuel storage areas is the use of fixed water sprinkler systems. However, this situation represents a significant safety hazard. According to the NFPA *Fire Protection Handbook*, water sprinklers can be permitted to be used on diesel fuel for control but not for extinguishment.

In "The Health and Safety Implications of the Use of Diesel-Powered Equipment in Underground Mines," a report by an interagency task group prepared for MSHA in 1985, the simple conclusion was that "water spray or fog usually will not extinguish diesel fuel fires."

In an underground coal mine, fire control is not sufficient; fire extinguishment is essential for the following reasons:

(1) Unlike an underground metal or nonmetal mine, the mineral in a coal mine is combustible. All fire prevention and protection provisions in an underground coal mine are aimed at preventing the ignition of the coal. In a metal or nonmetal mine, if fire control efforts are unsuccessful in extinguishing a fire on a piece of diesel equipment or a diesel fuel fire, personnel can be evacuated and the fire can be allowed to consume all available fuel materials, thereby self-extinguishing. In an underground coal mine, this practice would almost certainly result in the ignition of the coal and the consequent loss of part or all of the mine.
(2) Even if a fire does not grow in intensity or spread to the coal, toxic smoke and fire gases are produced as long as it burns, which can endanger persons within the mine.
(3) According to the NFPA *Fire Protection Handbook*, overpressure failure of containers exposed to fire is considered the principal hazard of closed-container flammable and combustible liquid storage.
(4) Even a "controlled" fire can cause such container failure, producing a fire so intense that the sprinkler system is unable to control it, much less extinguish it.
(5) Water sprays are not effective in extinguishing pressure fires, running fuel fires, and obstructed spill fires, all of which could occur in a diesel refueling area.
(6) Water supplies are limited in many underground mines. Fire "control" should be considered temporary, because when the water supply is depleted, the fire will grow immediately to the maximum intensity.
(7) The vapor pressure of diesel fuel increases with elevation, due to reduced barometric pressure. As a result, even fuels without flash point–reducing additives can become flammable, depending on the altitude at which they are used. This reduction in flash point can result in reclassification of

the diesel fuel to a Class IC flammable liquid. There is no clear consensus in the literature and industry practice as to the effectiveness of fixed water sprays in controlling and extinguishing fires involving Class IC flammable liquids. Although industry practice strongly favors fixed water sprays for such applications, the literature and available research results clearly indicate the ineffectiveness of fixed sprays on Class IC liquids, especially in the case of pressure fires, running fuel fires, and obstructed spill fires.

Therefore, water sprinkler systems installed for the protection of diesel fuel storage areas are considered inadequate; foam–water systems should be utilized. See the applicable sections of NFPA 16.

A.4.3.3.3.6.2 The alarm system that serves sprinklers protecting the drive area of a belt conveyor also should be permitted to serve as the fire detection system installed over that portion of the belt conveyor.

A.4.3.3.4.3.3 The clapper of a differential-type dry-pipe valve should be held off its seat during any test in excess of 345 kPa (50 psi), to prevent damaging the valve.

A.4.3.3.5.4 The special suppression system manufacturer is a good source for training regarding their equipment. Other acceptable training resources can be available.

A.4.3.3.5.5.2 The system could have several end-of-line drains if parts of the system dead end.

A.4.3.3.5.5.3 Deluge sprinklers might need to be flowed more frequently than monthly to keep the sprinkler systems clean. If caps are not used on water spray systems, they also might need to be flowed more frequently than monthly to keep the nozzles clean.

A.4.3.3.6.1 The actuation of a fire suppression system on self-propelled equipment should cause shutdown of the protected equipment.

A.4.3.3.6.1(11) Because exposure to some agents or their decomposition products could be hazardous to personnel, it is recommended that the appropriate NFPA standard for the agent under consideration be consulted to determine the agent's use and limitations, recognizing that the mine environment can make prompt evacuation difficult.

A.4.3.3.6.1(12) A dry chemical system should be inspected every 6 months in accordance with NFPA 17.

A.4.3.3.6.2 Pipe or hose supplying open spray nozzles should be sized to avoid excessive pressure loss. Open nozzles provide a good spray pattern with 6.9 kPa to 137.9 kPa (10 psi to 20 psi) of water pressure at the nozzles. If nozzle pressure exceeds 172.4 kPa (25 psi), additional or larger orifice nozzles can be permitted to be used to increase the water flow. If nozzle pressure is less than 137.9 Pa (20 psi), smaller orifice nozzles should be used to increase the pressure. The objective is to obtain the maximum flow of water at a pressure high enough to provide a reasonable spray pattern.

The water spray should be directed upward to wet the roof over the machine. This prevents the fire from spreading to the coal, which should be the primary objective of the fire protection system. Also, water will fall back down onto the machine, cooling and possibly extinguishing the flames. Alternatively, the nozzles can be directed at the fire hazard areas of the machine. The risk of this method is that the fire could be in an area not covered by the sprays and could spread to the coal.

A.4.3.4.1.1.1 Larger capacity extinguishers that provide more agent and longer discharge time are recommended.

A.4.3.4.1.2.3 It is not the intent of 4.3.4.1.2.3 to allow two lower rated fire extinguishers to be used to achieve a higher overall rating.

A.4.3.4.1.3.2 Visual inspections require documentation only at 6-month intervals.

A.4.3.4.2.1.1 Hydrants should be located to ensure that fire hose can be laid quickly from hydrants, which are located on the water line in any of the entries, through crosscuts to a fire located in parallel entries or crosscuts, rather than being located for convenient use in the entry where the water line is located.

A.4.3.4.2.1.4 Fire hose should be purchased as an entire unit that consists of the hose and couplings. The pressure rating should include both the hose and the couplings.

A.4.3.4.2.1.6 These threads are also referred to as National Pipe Straight Hose (NPSH). National Hose (NH) is also known as National Standard Thread (NST) and National Standard (NS).

Threads of 38 mm (1½ in.) or 50 mm (2 in.) hose couplings should be straight, iron pipe thread, now labeled NPSH. While it is always preferable to use fire hose adapters, NPSH couplings can be attached to standard male pipe threads. This is especially important because of the large number of hydrants needed on water lines.

Where the gasket of a fire hose coupling is in good condition, the coupling should be tightened with bare-hand pressure only. It usually will not leak. Hose wrenches are needed to uncouple hose only. Overtightening couplings with hose wrenches harms the gaskets.

Rocker lug couplings are preferred to pin-type couplings.

Most mines use NPSH threads because the couplings will attach to male pipe threads of the same size.

A.4.3.4.2.1.9 In many fires, fire hose has to be carried to the fire. If manual transport is necessary, the hose should be coiled into "bundles" or "doughnuts," with the male coupling at the center. In this manner, the hose is in proper orientation for use, and the exposed threads of the male coupling are protected. Hose lengths should be limited to 30.5 m (100 ft) or less, because greater lengths make the hose bundle too large and heavy.

It is sometimes preferable to coil bundles or doughnuts of fire hose starting with the approximate center point of the hose at the center of the bundle. A coil made in this manner positions the hose couplings on the outside so the hose can be laid starting at the hydrant moving toward the nozzle or from the nozzle back to the hydrant with equal efficiency.

Where high pressures are a concern, pressure relief devices can be used. The devices can be stored with the hose cache.

A.4.3.4.2.1.11 Consideration should be given to providing caches at intervals of less than 1524 m (5000 ft) where conditions warrant. A single hose cache might satisfy more than one of the required locations.

A.4.3.4.2.2 Fire hose requires special consideration at coal mines. Cotton- or linen-jacketed hose should not be used, as it is subject to mildew attack. Even mildew-treated hose does not endure. Rubber-lined and rubber-jacketed hose resists mildew attack, but this type of hose is heavy, stiff, and expensive. Neoprene-lined, polyester hose with rocker lug couplings is probably the best hose for mine use. The use of pin-type couplings should be avoided because the pins are easily broken or knocked off.

In low coal and where the water supply can deliver about 3.2 L/sec (50 gpm) at proper pressure, 38 mm (1½ in.) hose should be used. Where the water supply is able to provide 378 L/min to 460 L/min (100 gpm to 120 gpm) at proper pressure, 50 mm (2 in.) hose is preferable. Hose of 64 mm (2½ in.) has no advantage over 50 mm (2 in.) hose, and the extra weight and cost of 64 mm (2½ in.) hose is considerable.

Many mines have standardized on 38 mm (1½ in.) fire hose, even though their water lines can supply substantially more water than is required to get proper discharge from a 38 mm (1½ in.) hose nozzle. Some of these mines provide at least two valved connections (hydrants) in operating areas so that more than a single 38 mm (1½ in.) hose line can be used if needed. In some cases, short lengths of pipe with two or more hydrants are available for use at other points along the water lines. These multiple hydrants can be put in the line at joints where the water line is joined with grooved couplings.

While the total water flow of two 38 mm (1½ in.) hose lines is about the same as one 50 mm (2 in.) hose line, in the opinion of many experienced mine fire fighters, two 38 mm (1½ in.) hose lines provide greater flexibility during a fire-fighting operation.

A.4.3.4.6 While regulatory agencies have legal powers and responsibilities in a mine fire situation, the mine operator should have a preplanned organization capable of managing an effective fire-fighting effort. This organization has to be prepared, resolute, and capable. As part of periodic training, the organization should conduct fire drills that involve all levels of mine management. The regulatory agencies also should be invited to participate in fire drills. Training develops management capability and promotes cooperation between concerned agencies and mine management.

A.5.2 Fires adversely affect all types of self-propelled and mobile surface mining equipment, including, but not limited to, trucks, front-end loaders, crawlers, drills, shovels, and draglines. Most fires occur on or near engine exhaust systems, high-speed drive lines, malfunctioning high-pressure–high-temperature hydraulic systems, or faulty electrical components.

Total elimination of fire hazards is impossible, because sources of ignition and fuel for fires are inherent in the basic equipment design. The problem is further complicated by the collection of environmental debris. Therefore, efforts to reduce fire losses must be aimed at fire prevention and fire suppression.

To improve fire protection and prevention on surface mining equipment, some manufacturers of mining equipment emphasize the reduction of the fire potential of specific items in the original design of their equipment. Such items include turbochargers, exhaust manifolds and exhaust pipe shielding and insulation, location of combustible and flammable liquid reservoirs, and hydraulic and fuel-line routing.

Most surface mining equipment is required to have at least one hand-portable extinguisher mounted in a readily accessible location. Extinguishers are most effective when used by trained operators. However, considering the size and configuration of machines found at a mine, fires can be difficult or impossible to fight with a hand-held extinguisher. For this reason, fire suppression systems have been developed to aid in suppressing those fires that are hard to access and thereby to reduce “off-road” equipment fire losses.

The key to operator protection is early detection of fires to provide a warning to the operator, fuel shutoff to minimize fuel for the fire, and fire suppression during its earliest stages. Specialized systems to perform these functions can be required to protect the operator and the machines. To be totally effective, however, system operation must be fully understood by owners and operators, and provisions must be made for periodic inspection and maintenance.

Fire suppression systems, including hand-portable extinguishers, offer the mining industry a cost-effective tool by which personnel and investments in mining equipment can be protected.

A.5.3.4.1 This paragraph is not intended to include the boom of a dragline or shovel.

A.5.3.4.8(8) The same record tag or label can also indicate if recharging was performed.

A.5.3.5.2.1 A dry-chemical system is the preferred system for these areas.

A.5.3.5.2.2 Smoke detectors are not recommended because of the harsh environment.

A.5.3.5.3.1 Automatic systems are not necessary if the area is easily accessible for manual fire fighting.

A.5.3.5.4.2 Carbon dioxide would not be the best choice for fighting this type of fire due to the potential for the gas to be dispersed before the oxygen concentration is reduced enough to affect the fire.

For transformers over 5000 kVA, a fixed fire suppression system is recommended.

A.5.3.5.5.4 Based on the condition of the equipment, a higher frequency than annual scanning might be needed.

A.5.3.6.6 Equipment in this category is generally a vehicle weight of 90,720 kg (200,000 lb) or more and the size of a Hitachi 1800, Caterpillar 5230, Komatsu PC1000-6, Liebherr R984, DeMag H95, and Hitachi 1100.

A.5.3.8.1.1 Depending on the size of the vehicle and size of the fire, a 9.1 kg (20 lb) fire extinguisher could be more effective.

A.5.3.8.2.5 NFPA and manufacturers require 6-month inspections.

A.5.3.8.3.2 The following are examples of large equipment:

(1) Track dozer of 300 horsepower or more or 31,752 kg (70,000 lb) weight or more (e.g., Caterpillar D8R)
(2) Front-end loader of 400 horsepower or more and vehicle weight of 45,360 kg (100,000 lb) (e.g., Caterpillar 988)
(3) Wheel dozer of 300 horsepower or more and vehicle weight of 27,216 kg (60,000 lb) or more (e.g., Caterpillar 824G)
(4) Grader of 275 horsepower or more and vehicle weight of 24,948 kg (55,000 lb) or more (e.g., Caterpillar 16H)
(5) Pull-type scraper of 450 horsepower or more and vehicle weight of 44,453 kg (98,000 lb) or more (e.g., Caterpillar 631E)
(6) Scraper with push/pull twin engine of 450 horsepower and 490 horsepower or more and vehicle weight of 51,257 kg (113,000 lb) or more (e.g., Caterpillar 637E)

(7) Blast hole drill of 360 horsepower or more and weight of 30,845 kg (68,000 lb) or more (e.g., Ingersol-Rand DM-30)

A.5.3.8.3.3(4) Depending on the size of the equipment, additional ground-level manual actuators could be needed to provide quick access for manual activation of the system.

A.5.3.8.3.7 Six months is required by NFPA standards and manufacturers. The fire suppression system manufacturer is a good source for proper training regarding their equipment. Other acceptable training resources might be available.

A.6.1.2.2 Pneumatic coal-cleaning systems employ low-pressure air, usually pulsed, to effect a separation between relatively dry coal and mechanically associated impurities. The coal is usually 19 mm (¾ in.) and smaller, with up to 4 percent surface moisture. The pickup of fines from the feed coal in the process air stream creates a potentially explosive mixture. However, approximately 2 m/sec (400 ft/min) air velocity dissipates methane from the coal and, in practice, reduces explosion and fire hazards to very low proportions inside the equipment. Nonetheless, in the area surrounding the equipment, a potential fire hazard exists from unintentionally vented fine coal, and the potential for all hazards increases where the cleaners are preceded by thermal dryers.

A.6.2.1.4 Electrical components of ventilation equipment installed in the open and separated from the ventilation air being pulled from the hazardous area can be permitted to be considered nonhazardous.

A.6.2.1.4.1 Electrical equipment classified as "permissible" is certified as meeting the requirements of 30 CFR Part 18, Chapter 1.

A.6.2.1.6 Approved, intrinsically safe electrical equipment can be permitted to be used in any areas classified as "hazardous."

A.6.2.1.7 The intent of this requirement is the avoidance of arcing ignition sources resulting from differing electrical potentials between metal structural elements or between any such element and ground. The metal building elements might include the building frame (beams, columns, etc.), roof panels, building or control room panels, building utilities such as piping, ducts, or conduit, or other items. The objective of connecting metal parts to a ground is recognized as the best means of avoiding arcing between building elements or between those elements and ground or other grounded items. Any arrangement that provides both a good ground and a system of metal continuity from the ground to all metal elements achieves the intent. Where construction provides solid, secure metal-to-metal contact, the necessary continuity normally is provided. In cases where grounding is in question, resistance measurements should be made between the most remote elements or the most suspected elements or both and ground. If tests show less than 0.1 ohm resistance to ground, the arrangement can be permitted to be considered satisfactory. Testing should be done during dry weather when ground moisture is at a minimum. If lightning protection is provided, additional bonding of major building members to lightning system conductors might be required. Such bonding, however, can be permitted to serve the grounding needs covered by this requirement.

A.6.2.2.3.1 For further information, see NFPA 68.

A.6.2.2.5 Round ducts should be used wherever possible. All ducts should limit the number of bends and irregularities that could interfere with free airflow. Rectangular ducts should be used only where clearance prevents the use of round ducts. Rectangular ducts should be made as nearly square as possible to minimize the deposit of combustible materials.

A.6.2.3.1 Provision of 0.1 m^2 (1 ft^2) of building vent for each 2.3 m^3 (80 ft^3) of volume or space in which an explosion might occur generally is considered adequate for coal preparation plants, although the amount of venting needed to minimize structural damage that might be caused by a dust explosion varies according to the strength of the building, extent of the hazard, location and distribution of vents, properties of the coal dust, and other factors. Reference should be made to NFPA 68 in the sizing of explosion vents.

A.6.2.4 Bulk storage of Class II combustible liquids should be located outside the preparation plant and should be appropriate for the nature of the liquids and the quantities being stored. Tanks within the preparation plant should be of limited size, holding no more than the quantities needed for one and one-half shifts of operation. Each tank should be fitted with an overflow pipe of ample size to return the full volume of the transfer pump to the bulk storage tank. Tanks within the preparation plant should be isolated from the rest of the plant. The isolated area containing the tanks should be protected with an automatic sprinkler system that can provide a density of 6.1 L/min · m^2 (0.15 gpm/ft^2) over the entire area with all heads flowing. The floors beneath these tanks should have curbs, adequate slope, and floor drains able to handle the liquid from the tanks as well as the discharge from all automatic sprinklers.

A.6.3 A typical coal preparation plant process begins with raw coal entering a breaker where coal and undesirables, such as rocks, are separated. From the breaker, the coal is crushed and screened to size and then transferred, usually by belt conveyor, to the washing process. During the washing process, the dirty coal is separated from clay and rock by water washing or by chemical flotation. From the washing process, the clean, wet coal is conveyed to a drying process whereby surface moisture is reduced. A variety of dryers can be used, such as centrifugal, fluidized bed, or thermal disk processors. From the drying process, the clean, dry coal is conveyed to storage facilities, such as bins, silos, and coal barns, and then loaded out for transport or shipment by rail, surface, or conveyor for downstream use. *(See Figure A.6.3.)*

A.6.3.1.10 Phosphorescent exit signs can be used to identify building exits.

A.6.3.1.12.1 Refer to NFPA 850 for guidance on spacing transformers from buildings.

A.6.3.1.12.2 *NFPA 70* requires a 3-hour fire-rated room for transformers with combustible oil. This can be decreased to a 1-hour rated room if automatic fire suppression is provided.

A.6.3.1.12.3 Refer to NFPA 850 for guidance on fire barriers and spill containment for transformers.

A.6.3.2.2.1 Examples of where fixed protection might be needed in coal preparation include conveyor belts, galleries, tunnels, beneath bins, transfer houses, silo head houses, dust collectors, rotary compressors, and other areas such as switch gear rooms, control rooms, change houses, and combustible and flammable liquids storage or process areas. These areas should be considered ordinary hazards. Areas with noncombustible construction or noncombustible contents are areas where fixed protection might not be needed.

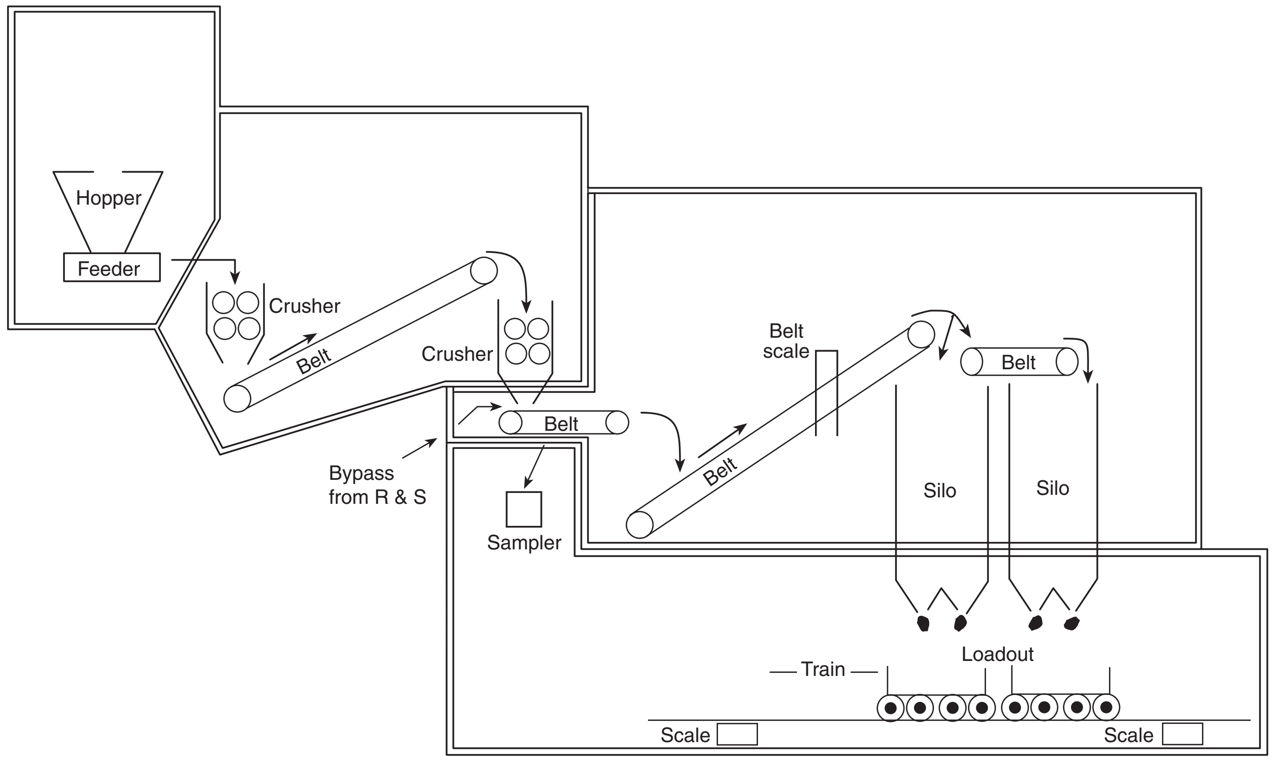

FIGURE A.6.3 Typical Coal Preparation Plant.

A.6.3.2.3.1 Standpipes should be located in exterior stairways. Where exterior stairways are not provided, standpipes should be located as close to stairways as practicable. This arrangement will provide fire fighters with ready access to fire-fighting water. Ideally, plants should have exterior stairways with standpipes on opposite ends of the plant. These stairways will provide fire fighters with two angles of attack.

When applying water, fire fighters should exercise care to avoid the use of solid hose streams in locations where the streams could create explosions by disturbing dust deposits.

Fire hose should not be used for washdown purposes.

In plants where the vibration anticipated is sufficient to cause movement of the fire protection system resulting in the wear of water piping at the hangers, it might be necessary to install vibration absorbers.

A.6.3.2.4.1 A readily available supply can include a dedicated fire protection water supply, a pond or other large body of water, an industrial process water system, or large water trucks (tankers). If water trucks (tankers) are used, they should be of a capacity and quantity to deliver a continuous source of water for the duration of the fire-fighting effort. Personnel should be trained in emergency vehicle operation and mobile water supply shuttle procedures. If an impounded body of water is provided, it should be close and accessible enough to the protected property to allow fire fighters a quick response.

A.6.3.2.4.4 Chapter 8 and Appendix G of NFPA 1142 outline suggested methods for determining the estimated water supply (fire flow) that can be necessary for fire-fighting purposes.

A.6.3.2.6.3 A gaseous fire suppression system can also be considered for important motor control center (MCC) rooms or for rooms that contain input/output (I/O) cabinets. A gaseous fire suppression system or smoke detector system can also be considered for the preparation plant control room.

A.6.4.1 Thermal coal dryers can be of any type that conforms to the requirements of Section 6.4, including rotary dryers, continuous carrier dryers, vertical tray and cascade dryers, multilouver dryers, suspension or flash dryers, and fluidized bed dryers. These direct-fired convection-type dryers constitute the majority of currently operational units. Almost all these units utilize special direct-fired air heater–type furnaces, usually coal fired by stokers or by pulverized fuel systems.

A.6.4.2.5 For further information, see NFPA 68.

A.6.4.2.7 Thermal oil systems are used in coal preparation plants to indirectly dry coal in thermal disk processors. Severe losses have occurred due to lack of inadequate sprinkler protection, poor siting and confinement of expansion and storage tanks and heaters, improper piping arrangement, and inadequate interlocks and controls. Even though the woodworking industry has unique equipment that needs hot oil applications, the hot oil heating and distribution systems are similar, and the concepts provided in NFPA 664 can be utilized for the coal preparation industry.

Chapter 8 of NFPA 664 is the primary reference in NFPA standards for thermal oil systems used in industrial processes. While NFPA 664 addresses loss prevention in a specified occupancy (wood products), other standards might be applicable to any industrial process featuring thermal oil systems.

A.6.4.5 Guidance for design of vent ducts is provided in NFPA 68.

A.7.1 Gas and electric welding or cutting procedures should be in accordance with NFPA 51B.

A.7.1.2.1 For additional information, see NFPA 326 and AWS F4.1, *Recommended Safe Practices for the Preparation for Welding and Cutting Containers and Piping That Have Held Hazardous Substances.*

A.7.1.2.5 If the coal is susceptible to spontaneous combustion, water should not be used to wet down the area. Rock dust should be used.

A.7.1.4.1 For information on labeling of compressed and liquefied gas cylinders, see CGA C-7, *Guide to the Preparation of Precautionary Labeling and Marking of Compressed Gas Containers.*

A.7.1.5.9 For information on labeling of compressed and liquefied gas cylinders, see CGA C-7, *Guide to the Preparation of Precautionary Labeling and Marking of Compressed Gas Containers.*

A.7.3.1 Buried tanks do not create a fire hazard but preferably should be at least 1.5 m (5 ft) from all buildings.

A.7.3.1.2 Information on the design and construction of atmospheric tanks can be found in API 650, *Standard for Welded Steel Tanks for Oil Storage*; UL 142, *Standard for Steel Above-Ground Tanks for Flammable and Combustible Liquids*; or UL 80, *Standard for Steel Inside Tanks for Oil Burner Fuels or Other Combustible Liquids.*

Low pressure tanks and pressure vessels can be permitted to be used as atmospheric tanks.

A.7.3.2 This can be accomplished by diking or drainage with remote impounding. See 22.11.2 of NFPA 30 for additional details.

A.7.3.3.4 For additional information see Annex B of NFPA 30.

A.7.3.3.6 For additional information see Section 27.8 of NFPA 30.

A.7.4.5 Combustible liquid storage in drums or totes preferably should be stored outside.

A.7.5.1.1 Electrical equipment classified as "permissible" is certified as meeting the requirements of 30 CFR Part 18, Chapter 1.

A.7.6.2.2 Containers and portable tanks for combustible liquids authorized by the U.S. Department of Transportation should be acceptable as storage containers.

A.7.6.2.10 Information on the design and construction of pressure vessels can be found in the ASME *Boiler and Pressure Vessel Code*, "Code for Unfired Pressure Vessels," Section VIII, Division I.

A.7.6.2.13 Information on venting can be found in API 2000, *Standard for Venting Atmospheric and Low-Pressure Storage Tanks.*

A.7.6.3 The terms *transfer* and *transport* are used synonymously to mean movement of combustible liquid in closed containers, tanks, safety cans, or pipelines between underground locations.

A.7.6.3.10 The greatest risk of fire involving substantial quantities of combustible liquids exists when rail supply cars are being moved, especially on a trolley wire–powered rail system. In contrast, cars parked where trolley and feed wire are absent or de-energized represent a distinctly lower risk. Limiting the storage of lubricants in operating areas to a 3-day rather than a 1-day supply reduces the frequency of transport and, as a result, the overall risk of fire.

A.7.6.3.12 Where pressurized pipeline systems are used for combustible liquid transfer, consideration should be given to providing a pressure-sensing interlock downstream of the transfer pump discharge. This interlock should be suitable for Class I, Division 2 locations and should be arranged to shut down the pump immediately upon loss of line pressure.

A.7.6.5 The principal Class II combustible liquid used in a coal mine is diesel fuel.

A.7.6.5.2.7 There are no listed doors for storage areas in underground mines.

A.7.6.5.2.10 Information on tank foundations can be found in Appendix E of API 650, *Standard for Welded Steel Tanks for Oil Storage*, and Appendix B of API 620, *Recommended Rules for the Design and Construction of Large, Welded, Low-Pressure Storage Tanks.*

A.7.6.8 No requirements for bonding or grounding to dissipate static electricity are included in NFPA 30, which does not require bonding or grounding for combustible liquids handled at temperatures below their flash points.

It is recognized, however, that certain conditions can exist that could necessitate bonding or grounding, such as those of temperature and altitude, which can reduce the flash point of diesel fuel.

For additional information on static electricity, see NFPA 77.

A.8.5 A manifold system should be considered for all new installations in shop buildings.

A.8.6.2 Automatic sprinkler protection provides the most affordable fire protection. Where water supplies are adequate, sprinkler protection should be strongly considered for office and warehouse occupancies.

A.8.6.3 If an adequate water supply is available, a fire hydrant should be installed within 15.2 m (50 ft) of the warehouse, shop, and office building.

A.8.6.6 For office buildings, a minimum of one 4.6 kg (10 lb) extinguisher should be provided for every 279 m^2 (3000 ft^2) of building area. Travel distance from any point to the nearest extinguisher should not exceed 22.9 m (75 ft). For shop and warehouse areas, a minimum 9.1 kg (20 lb) extinguisher should be provided for every 22.9 m (75 ft) travel distance within the building.

Large-wheeled, dry-chemical or foam extinguishers should be considered for shop and warehouse areas. The type of fires that can occur in these areas can be too large to be handled by a hand-held extinguisher.

A.9.1 Unless the conveyor is very long, burning coal on a moving belt is not likely to ignite the belt. Also, if the belt should ignite, the burning of the belt is likely to be extinguished after the burning coal has been discharged and the belt continues to run. No reports of running conveyor belts in and around preparation plants that have caught fire and burned have been located. Every reported case of belts catching fire and burning has occurred after the belts have been stopped.

Some preparation plants use the froth flotation process to separate impurities from fine coal. The agents typically used in froth flotation are Class II combustible liquids. The coal recovered from the froth cells is coated minimally with these agents. It has been found that frothed coal carried on conveyor belts will coat the belting with the agents, causing the coated belting to ignite easily and the flame spread to become significantly more rapid than usual. It is recommended that belts that carry frothed coal be protected with automatic sprinklers. While the froth flotation process operates as a water slurry and presents no risk of fire, the reagents normally used are No. 2 fuel oil and methyl isobutyl carbinol (MIBC), which are Class II combustible liquids.

Fortunately, evidence of heating is easy to detect. During the early stage of heating, the odor is unmistakable. When heating is more advanced, smoke and steam also might be apparent. If the hot coal is in an exposed storage pile, the hot material can be dug out and wetted. If the hot material has to be loaded onto a conveyor belt, the loading areas should be hosed down, and water should be applied to the hot material before or as it is loaded onto the belt.

Tunnels under silos or storage piles should be ventilated adequately and should be protected with a system of automatic sprinklers. Separate hose for fire fighting should be provided. The main tunnel should have exit routes at opposite ends of the tunnel.

A.9.1.1 The U.S. Mine Safety and Health Administration standards found in 30 CFR for fire-retardant conveyor belt materials should be used as a guide. Fire-retardant belt materials will burn and, therefore, might require additional fire protection.

Stockpile conveyors, reclaim conveyors, and conveyors going to loadout silos or bins should be fire-resistant belt.

Rip detection also can be considered for long runs or critical belt systems. Critical factors to be considered should be the impact on production if the belt is lost, the cost of the belt itself, availability of spare belting, length of time to repair the belt, and alternatives to bypass the belt if it is lost.

A.9.1.2 A steel deck, which often is placed between the top and bottom strands of a belt conveyor, should not be used. It is recommended that existing decks be removed.

Belt galleries that use supporting trusses with substantial length of span should be set entirely beneath the belt so that, in the event of a fire, the loaded structural members of the truss are not seriously exposed to the heat of the burning belt. The supports for the troughing and return idlers should not be structural parts of the truss. The covering for the belt should be partially open on the walkway side, allowing access to the belt and to the belt idlers for maintenance and fire fighting.

Belts that are located entirely within relatively long-span supporting trusses should be protected by a fixed fire protection system.

Provision for removing burning coal to a safe area utilizing conveyors should be considered. These conveyors might require manual water spray to cool smoldering coal. Flanged openings can be used for removing burning coal if adequate planning and equipment have been provided.

A.9.4.3 To minimize potential frictional ignition, alignment switches can be permitted to be provided at intervals sufficient to prevent the belt from contacting such materials.

A.9.4.6.3.1.3 The flexible hose should be attached at a point where it is least exposed to a fire ignition source, such as the drive rollers.

A.9.4.6.3.2(8) Pipe hangers should be designed to support five times the weight of the water-filled pipe plus 114 kg (250 lb) at each point of piping support. Hanger rods should be at least 9.5 mm (3⁄8 in.) thick for pipe up to 102 mm (4 in.). U hooks should be at least 8 mm (5⁄16 in.) thick for pipes up to 50.8 mm (2 in.). Eye rods should be at least 9.5 mm (3⁄8 in.) thick for pipe up to 102 mm (4 in.). This information is taken from Section 9.1 of NFPA 13.

A.9.4.7.4 Adjustable fog nozzles should be provided for all hoses.

A.9.4.8 Transfer points can also require dust suppression.

A.9.5 The key concept in coal storage is to prevent spontaneous combustion. Preventing spontaneous combustion requires all of the following:

(1) Eliminating air entrainment in the coal
(2) Eliminating heat sources near the storage
(3) Preventing moisture in the coal

A.10.2.2 This process can be accomplished by pressurization, sealing the room, or air filtration. Housekeeping and coal-wetting agents also can be used to reduce the coal dust in the room. Coal dust should not be allowed to accumulate inside electrical cabinets.

A.10.4.2 CO_2 systems are not recommended for occupied areas. If a CO_2 system is used, it should have a maintenance lockout.

A.10.5.1 If the building has a standpipe system, a fire hose can be used as a substitute for a fire extinguisher as detailed in NFPA 10.

A.11.1 For mines where the response time of the public fire department is in excess of 30 minutes, an emergency organization that is trained in basic fire-fighting techniques should be developed. Training should consist of the use of large extinguishers and small hose streams 38 mm (1½ in.) to provide immediate fire-fighting efforts until the local fire department arrives. This training would also include procedures for using fire hose off a water truck or any other nearby sources of water. A crew consisting of at least five members for each shift should be trained in fire-fighting operations. Detailed fire-fighting procedures should be developed for each type of potential fire, for example, dragline, shovel, mobile equipment, warehouse, and office. Training should be conducted based on those scenarios.

A.11.2.5.1 Two portable water cars, readily available, can be used in place of the water lines prescribed in 11.2.5.1.

A.11.2.5.5 A multiple hydrant is a short length of 76.2 mm (3 in.) or 102 mm (4 in.) pipe, usually with three valved outlets (hydrants) to which fire hose lines can be connected. If the mine is equipped with a foam generator for fighting fires, there should be an additional outlet to feed the generator. An alternative is to assemble the hydrants from grooved pipe fittings that also have threaded tee connections to which the valved outlets are connected. The multiple hydrants should have adapters that allow them to be connected to any of the pipe sizes in use at the mine.

A.11.3.1 Surface fire-fighting teams should be trained and equipped in accordance with 11.2.2.

Standard for

Fire Prevention and Control in Metal/Nonmetal Mining and Metal Mineral Processing Facilities

2015 Edition

This edition of NFPA 122, *Standard for Fire Prevention and Control in Metal/Nonmetal Mining and Metal Mineral Processing Facilities*, was prepared by the Technical Committee on Mining Facilities. It was issued by the Standards Council on November 11, 2014, with an effective date of December 1, 2014, and supersedes all previous editions.

This edition of NFPA 122 was approved as an American National Standard on December 1, 2014.

Origin and Development of NFPA 122

In 1978 the Technical Committee on Mining Facilities, through its membership and current Mine Safety and Health Administration regulations, identified the need for guidance in storage and handling of flammable and combustible liquids in underground nonmetal mines. The first edition of NFPA 122 was approved in 1986 as a result and was titled NFPA 122, *Storage of Flammable and Combustible Liquids Within Underground Metal and Nonmetal Mines (Other than Coal).* The second edition was issued in 1990 and included a variety of minor editorial changes to provide consistency with the other NFPA Mining Facilities documents.

The 1995 edition was a complete revision that focused the document on the overall fire protection of metal and nonmetal mines, as indicated by the document's new title, NFPA 122, *Standard for Fire Prevention and Control in Underground Metal and Nonmetal Mines.* Furthermore, this edition incorporated the requirements that were previously included in NFPA 124, *Standard for Fire Protection of Diesel Fuel and Diesel Equipment in Underground Mines*, which was withdrawn. Further changes included editorial corrections and revisions that provided consistency with other NFPA mining-related standards.

The 2000 edition of the standard was reconfirmed by the technical committee. There were no technical changes made. The fire risk assessment material in Appendix A was editorially moved to Appendix B.

In 2004, the Technical Committee reorganized the mining standards and combined NFPA 121, *Standard on Fire Protection for Self-Propelled and Mobile Surface Mining Equipment*, with NFPA 122. The committee also added a new Chapter 13, Fire Protection of Surface Metal Mineral Processing Plants. The committee incorporated the concept of conducting a fire risk assessment throughout the standard.

For the 2010 edition, the technical committee assigned a task group the responsibility of revising NFPA 122 to update the existing fire protection requirements that were included in portions of existing Sections 4.3 and 7.4 to improve operator safety and the reliability of the required suppression systems. Similarly, Chapter 12, Fire Prevention and Fire Protection of Surface Mining Equipment, was completely revised to make it consistent with fire protection industry practices and the updated provisions in NFPA 120, *Standard for Fire Prevention and Control in Coal Mines.*

Concurrently, another task group was assigned the responsibility of revising NFPA 122 to include fire protection requirements for hydro-metallurgical solvent extraction (SX) plants. This resulted in two new sections being added into Chapter 13, Section 13.18 for new and existing hydro-metallurgical solvent extraction (SX) plants and Section 13.19 for new hydro-metallurgical solvent extraction (SX) plants. Sections 13.18 and 13.19 include a fire risk assessment of the facility and requirements for fixed fire suppression systems. To support these new sections on hydro-metallurgical solvent extraction (SX) plants, additional references and definitions were added to Chapters 2 and 3, respectively.

NFPA and National Fire Protection Association are registered trademarks of the National Fire Protection Association, Quincy, Massachusetts 02169.

The Metal/Nonmetal Mining Task Group for the 2010 edition consisted of the following members: Larry Moore, Chair, FM Global; Steve Behrens, Swiss Re; Dennis Brohmer, Tyco Fire Suppression & Building Products; J. J. Kenny, Marsh; L. Harvey Kirk, MSHA; Mario Orozco, Zurich; Pierre Tousignant, QIT Quebec; and Mark Yarbro, Freeport MacMoran Mining.

The 2014 edition of NFPA includes various technical and editorial updates. The committee has established a common definition and a protection scheme for *self-propelled*, *mobile equipment*, and *portable equipment*.

This list represents the membership at the time the Committee was balloted on the final text of this edition. Since that time, changes in the membership may have occurred. A key to classifications is found at the back of the document.

NOTE: Membership on a committee shall not in and of itself constitute an endorsement of the Association or any document developed by the committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on safeguarding life and property against fire, explosion, and related hazards associated with underground and surface coal and metal and nonmetal mining facilities and equipment.

NFPA 122

Standard for

Fire Prevention and Control in Metal/Nonmetal Mining and Metal Mineral Processing Facilities

2015 Edition

IMPORTANT NOTE: This NFPA document is made available for use subject to important notices and legal disclaimers. These notices and disclaimers appear in all publications containing this document and may be found under the heading "Important Notices and Disclaimers Concerning NFPA Standards." They can also be obtained on request from NFPA or viewed at www.nfpa.org/disclaimers.

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates that explanatory material on the paragraph can be found in Annex A.

A reference in brackets [ ] following a section or paragraph indicates material that has been extracted from another NFPA document. As an aid to the user, the complete title and edition of the source documents for extracts in mandatory sections of the document are given in Chapter 2 and those for extracts in informational sections are given in Annex C. Extracted text may be edited for consistency and style and may include the revision of internal paragraph references and other references as appropriate. Requests for interpretations or revisions of extracted text shall be sent to the technical committee responsible for the source document.

Information on referenced publications can be found in Chapter 2 and Annex C.

Chapter 1 Administration

1.1 Scope.

1.1.1* This standard covers minimum requirements for safeguarding life and property against fire and related hazards associated with metal and nonmetal underground and surface mining and metal mineral processing plants.

1.1.2 As applies to underground mining, this standard shall cover only the following:

(1) Diesel-powered equipment
(2) Storage and handling of flammable and combustible liquids

1.1.3 As applies to underground mining, this standard shall not cover flammable and combustible liquids produced in underground mines, such as shale oil mines.

1.1.4 As applies to surface mining, this standard shall cover only the following:

(1) Mobile equipment in use without its own motive power train and normally moved by self-propelled equipment
(2) Self-propelled equipment that contains a motive power train as an integral part of the unit and is not rail-mounted

1.1.5 This standard shall not cover buildings or employee housing and support facilities for a mining operation, or preparation or use of explosives.

1.1.6* As applies to metal mineral processing, this standard shall cover fire and related hazards associated with metal mineral processing plants — whether underground or on the surface — including but not limited to conveying, crushing, fine milling, beneficiation, flotation, hydro-metallurgical solvent extraction, drying, filtering, ore and concentrate storage, and support facilities for the mineral processing activity.

1.1.7* As applies to surface metal mineral processing plants, this standard shall not cover the following:

(1) Solvent extraction plants
(2) Pressure-leaching processes
(3) Alumina refineries
(4) Nonmetal mineral processing plants
(5) Metal smelters including roasting, sintering, and calcining
(6) Metal refineries such as electrowinning or electrorefining processes
(7) Gas, liquid, or solid waste handling or storage systems

1.1.8 Nothing in this standard is intended to prohibit the use of new methods or devices, provided sufficient technical data are submitted to the authority having jurisdiction to demonstrate that the new method or device is equivalent in quality, effectiveness, durability, and safety to that specified by this standard.

1.2 Purpose. This standard shall be intended for use by those charged with fire prevention and fire protection or with responsibility for purchasing, designing, installing, testing, inspecting, approving, listing, operating, or maintaining the following:

(1) Facilities and equipment for the storage and handling of flammable and combustible liquids within underground metal and nonmetal mines
(2) Diesel-powered equipment in underground metal and nonmetal mines, mobile and self-propelled surface mining equipment in metal and nonmetal mines, and metal mineral processing plants

1.3 Application. Only those skilled in fire protection shall be permitted to design and supervise the installation of fire protection systems.

1.4 Retroactivity. The provisions of this standard reflect a consensus of what is necessary to provide an acceptable degree of protection from the hazards addressed in this standard at the time the standard was issued.

1.4.1 Unless otherwise specified, the provisions of this standard shall not apply to facilities, equipment, structures, or installations that existed or were approved for construction or installation prior to the effective date of the standard. Where specified, the provisions of this standard shall be retroactive.

1.4.2 In those cases where the authority having jurisdiction determines that the existing situation presents an unacceptable degree of risk, the authority having jurisdiction shall be permitted to apply retroactively any portions of this standard deemed appropriate.

1.4.3 The retroactive requirements of this standard shall be permitted to be modified if their application clearly would be impractical in the judgment of the authority having jurisdiction, and only where it is clearly evident that a reasonable degree of safety is provided.

Chapter 3 Definitions

3.1 General. The definitions contained in this chapter shall apply to the terms used in this standard. Where terms are not defined in this chapter or within another chapter, they shall be defined using their ordinarily accepted meanings within the context in which they are used. *Merriam-Webster's Collegiate Dictionary*, 11th edition, shall be the source for the ordinarily accepted meaning.

3.2 NFPA Official Definitions.

3.2.1* Approved. Acceptable to the authority having jurisdiction.

3.2.2* Authority Having Jurisdiction (AHJ). An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

3.2.3 Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

3.2.4* Listed. Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

3.2.5 Shall. Indicates a mandatory requirement.

3.2.6 Should. Indicates a recommendation or that which is advised but not required.

3.2.7 Standard. An NFPA Standard, the main text of which contains only mandatory provisions using the word "shall" to indicate requirements and that is in a form generally suitable for mandatory reference by another standard or code or for adoption into law. Nonmandatory provisions are not to be considered a part of the requirements of a standard and shall be located in an appendix, annex, footnote, informational note, or other means as permitted in the NFPA Manuals of Style. When used in a generic sense, such as in the phrase "standards development process" or "standards development activities," the term "standards" includes all NFPA Standards, including Codes, Standards, Recommended Practices, and Guides.

3.3 General Definitions.

3.3.1 Boiling Point. The temperature at which the vapor pressure of a liquid equals the surrounding atmospheric pressure. [**30,** 2015]

3.3.2 Closed Container. A container, as herein defined, so sealed by means of a lid or other device that neither liquid nor vapor will escape from it at ordinary temperatures. [**30,** 2015]

3.3.3 Combustible. Capable of undergoing combustion.

3.3.4 Combustible Liquid Storage Area.

3.3.4.1 ***Combustible Liquid Storage Area — Fixed.*** An area used for storage of Class II and Class III combustible liquids that is infrequently moved, and where the aggregate quantity present shall not exceed 18,925 L (5000 gal) . Handling of liquids incidental to transfer can take place within a storage area. [**120,** 2015]

3.3.4.2 ***Small Combustible Liquid Storage Area — Portable.*** An area used for storage of Class II and Class III combustible liquids that is periodically moved, and where the aggregate quantity present does not exceed 3785 L (1000 gal). Handling of liquids incidental to transfer can take place within a storage area. [**120,** 2015]

3.3.5 Combustion. A chemical process of oxidation that occurs at a rate fast enough to produce heat and usually light in the form of either a glow or flame. [**5000,** 2015]

3.3.6 Container. Any vessel of 450 L (119 gal) or less capacity used for transporting or storing liquids. [**30,** 2015]

3.3.7 Cutoff Room. A room within a building and having at least one exterior wall.

3.3.8 Diesel-Powered Equipment. Any device powered by a diesel engine.

3.3.9* Emergency Egress.

3.3.10 Equipment Operator. The authorized person who starts, controls, or stops mining equipment.

3.3.11 Fire Detector. An automatic device designed to detect the presence of fire and initiate action.

3.3.12 Fire Risk Assessment. The evaluation of the relative danger of the start and spread of fire; the generation of smoke, gases, or toxic fumes; and the possibility of explosion or other occurrence endangering the lives and safety of personnel or causing significant damage to property.

3.3.13 Fixed Diesel Fuel Storage Area. A designated location used to facilitate fuel dispensing for the storage of diesel fuel in containers, tanks, or both, exceeding an aggregate quantity of 2498 L (660 gal), from which tanks or containers are not moved or transported within the mine.

3.3.14 Fixed Fire-Suppression System. An engineered or pre-engineered total flooding or local application system consisting of a fixed supply of extinguishing agent permanently connected for fixed agent distribution to fixed nozzles that are arranged to discharge an extinguishing agent into an enclosure (total flooding), directly onto a hazard (local application), or a combination of both; or an automatic sprinkler system.

3.3.14.1 ***Engineered Systems.*** Those systems requiring individual calculation and design to determine the flow rates, nozzle pressures, pipe size, area, volume protected by each nozzle, quantity of suppression agent, number and types of nozzles, and their placement in a specific system.

3.3.14.2 ***Pre-Engineered Systems.*** Those systems having predetermined flow rates, nozzle pressures, and quantities of extinguishing agent and having specific pipe size, maximum and minimum pipe lengths, flexible-hose specifications, number of fittings, and number and types of nozzles. [**17,** 2013]

3.3.15 Flammable Liquid Storage Area. Area used for storage of Class I liquids. [**120,** 2015]

3.3.15.1 ***Large Flammable Liquid Storage Area.*** An area used for storage of Class I liquids where the aggregate quantity present is greater than 37.8 L (10 gal).

3.3.15.2 ***Small Flammable Liquid Storage Area.*** An area used for storage of Class I liquids where the aggregate quantity present is 37.8 L (10 gal) or less.

3.3.16* Flash Point. The minimum temperature of a liquid at which sufficient vapor is given off to form an ignitible mixture with the air, near the surface of the liquid or within the vessel used, as determined by the appropriate test procedure and apparatus specified in Section 4.4 of NFPA 30. [**30,** 2015]

3.3.17 Hand Hose Line System. A hose and nozzle assembly connected by fixed piping or connected directly to a supply of extinguishing agent.

3.3.18 Hot Work. Work involving burning, welding, or a similar operation that is capable of initiating fires or explosions. [**51B,** 2014]

3.3.19 Inherent Safety. A protection layer that relies on the reduction or elimination of hazardous conditions, materials, or processes through changes in the chemistry, physics, and physical design of a process.

3.3.20 Liquid.

3.3.20.1 ***Combustible Liquid.*** Any liquid that has a closed-cup flash point at or above 37.8°C (100°F), as determined by the test procedures and apparatus set forth in Section 4.4 of NFPA 30. Combustible liquids are classified according to Section 4.3 of NFPA 30. [**30,** 2015]

3.3.20.2 ***Flammable Liquid.*** Any liquid that has a closed-cup flash point below 37.8°C (100°F), as determined by the test procedures and apparatus set forth in Section 4.4 of NFPA 30, and a Reid vapor pressure that does not exceed an absolute pressure of 40 psi (276 kPa) at 37.8°C (100°F), as determined by ASTM D323, *Standard Test Method for Vapor Pressure of Petroleum Products (Reid Method)*. Flammable liquids are classified according to Section 4.3 of NFPA 30. [**30,** 2015]

3.3.21 Metal and Nonmetal. Minerals other than coal.

3.3.22 Metal Mineral. Belonging to the class of inorganic metal compounds occurring in the earth's crust that are transformed into pure metals by metallurgical refining, including gold, silver, lead, zinc, nickel, and copper.

3.3.23* Metal Mineral Processing Plant. A surface processing facility used to size, separate, and concentrate valuable metals from raw ore.

3.3.24 Mine Operator. Any owner, lessee, or other person who operates, controls, or supervises a mine.

3.3.25* Mineral. A naturally formed inorganic substance occurring in the earth's crust and having a consistent and distinct set of physical properties and a composition that can be expressed by a chemical formula.

3.3.26 Mobile Equipment. Wheeled, skid-mounted, track-mounted, or rail-mounted equipment capable of moving or being moved.

3.3.27* Noncombustible Material. Material that, in the form in which it is used and under the conditions anticipated, will not ignite, burn, support combustion, or release flammable vapors when subjected to fire or heat.

3.3.28 Nonmetal Mineral. Belonging to the class of inorganic structural and industrial minerals that do not become metals through metallurgical refining, such as potash, asbestos, sulfur, granite, and rock aggregates.

3.3.29 Ore. A mixture of valuable metal mineral and waste rock.

3.3.30 Pipeline System. An arrangement of piping, valves, connections, and allied equipment installed in a mine for the purpose of transporting, transferring, or dispensing flammable or combustible liquids.

3.3.31 Portable Extinguisher. An extinguisher of the hand-held or wheeled type that is capable of being carried or moved about; or a transportable system consisting of a hose reel or rack, hose, and discharge nozzle assembly connected to a supply of suppressant.

3.3.32 Pressure Vessel. A container or other component designed in accordance with the ASME *Boiler and Pressure Vessel Code*, or CSA B51, *Boiler, Pressure Vessel and Pressure Piping Code.* [**52**, 2013]

3.3.33* Safe Area. An area where hot work such as cutting and welding, burning, or grinding is done routinely and frequently and has been identified, inspected, and designated as being safe for hot work operations.

3.3.34 Safety Can. A listed container of not more than 20 L (5.3 gal) capacity having a screen or strainer in each fill and pour opening and having a spring-closing lid and a spout cover designed to safely relieve internal pressure when exposed to fire. [**30,** 2015]

3.3.35 Self-Closing Doors. Doors that, when opened and released, return to the closed position. [**80,** 2013]

3.3.36 Self-Igniting Ore. See 3.3.37, Self-Igniting Rock.

3.3.37* Self-Igniting Rock. Rock containing minerals prone to self-heating and ignition due to chemical oxidation and spontaneous combustion, if such minerals are present in sufficient amounts and occur in a form known to present a spontaneous combustion hazard.

3.3.38 Self-Propelled Equipment. Any unit that contains a motive power train as an integral part of the unit.

3.3.39* Solvent Extraction (SX) Facility. Within this standard, a solvent extraction (SX) facility is a hydro-metallurgical processing facility associated with a mining or mineral refining facility that uses organic or alcohol-based solvents to extract desirable metals.

3.3.40 Suitable. That which is appropriate and has the qualities or qualifications to meet a given purpose, occasion, condition, function, or circumstance.

3.3.41 Tank. A closed vessel having a liquid capacity in excess of 227 L (60 U.S. gal).

3.3.41.1 ***Atmospheric Tank.*** A storage tank that has been designed to operate at pressures from atmospheric through a gauge pressure of 6.9 kPa (1.0 psi) (i.e., 760 mm Hg through 812 mm Hg) measured at the top of the tank. [**30,** 2015]

3.3.41.2 ***Low Pressure Tank.*** A storage tank designed to withstand an internal gauge pressure above 3.5 kPa (0.5 psi) but not more than 103.4 kPa (15 psi).

3.3.41.3 ***Portable Tank.*** Any closed vessel having a liquid capacity over 227 L (60 gal) and not intended for fixed installation. [**30,** 2015]

Chapter 4 General

4.1 General. Provisions in Chapter 4 shall apply to all underground and surface metal and nonmetal mines and to surface metal mineral processing plants, subject to scope limitations.

4.2 Housekeeping.

4.2.1 Spills, leaks, excess lubricants, and combustible materials such as oil-soaked wastes, rubbish, and accumulations of environmental debris shall not be allowed to accumulate in quantities that could create a fire hazard, as determined by a fire risk assessment.

4.2.2 Approved metal receptacles shall be provided where oil-soaked wastes or rubbish are not immediately removed to a safe place for disposal.

4.2.3 Maintenance operations shall include written procedures and practices to identify and prevent leakage and accidental escape of flammable or combustible liquids.

4.2.4 Spillage of flammable or combustible liquids shall be cleaned up.

4.2.5 Where flammable or combustible liquids are used or handled, means shall be provided to dispose of leakage or spills.

4.2.6 Access routes shall be kept clear of obstructions to allow access and use of fire protection equipment.

4.3 Ignition Source Control.

4.3.1 Smoking and open flames shall be prohibited in areas or locations where fire or explosion hazards exist.

4.3.2 Signs warning against smoking and open flames shall be posted conspicuously.

4.4 Hot Work.

4.4.1 Hot work shall be in accordance with NFPA 51B.

4.4.2 Compressed gases used for hot work shall be stored in accordance with Chapter 4 of NFPA 51.

4.4.3 A hot work permit system shall be developed for all areas of the mine and surface metal processing facilities where hot work is conducted outside of designated safe areas.

4.4.4 Hot work shall be performed only by personnel who have been trained in precautions and procedures for safety in these operations.

4.4.5 Before hot work is performed, prior approval shall be granted by the plant/mine superintendent or designated agent.

4.4.6 All hot work equipment shall be maintained to ensure it is in proper condition.

4.4.7 A flashback arrester shall be installed at the outlet of each pressure regulator on compressed flammable gas cylinders.

4.4.8 When not in use, the compressed gas cylinder valve shall be closed.

4.4.9 Appropriate personal protective equipment, including gloves, goggles, and welding hoods, shall be worn by personnel during hot work operations.

4.4.10 Combustible materials such as oil, grease, wood, or cardboard boxes and rags within 4.6 m (15 ft) of hot work shall be removed, covered, or wetted down before hot work is started.

4.4.11 Hot work shall not be performed within 15.24 m (50 ft) of explosives, blasting agents, or mine fuel storage areas, unless separated by a suitable noncombustible barrier.

4.4.12 Open gear cases or other exposed machinery components containing lubricants located within 4.6 m (15 ft) shall be covered with noncombustible material before hot work is started.

4.4.13 Noncombustible barriers shall be installed below hot work operations that are being performed in or over shafts, silos, or bins, and similar openings that are constructed of or contain combustible materials or flammable gases.

4.4.14 Openings or cracks in walls, partitions, floor decks, or ducts shall be covered tightly to prevent the passage of sparks to adjacent areas.

4.4.15 Where hot work is done on a metal wall, partition, ceiling, or roof, precautions shall be taken to prevent ignition of combustibles on the other side due to conduction or radiation.

4.4.16 Noncombustible barriers shall be installed below hot work operations that are being performed over empty open-topped tanks or process equipment that are lined with rubber, plastic, or other combustible linings.

4.4.17 As an alternative to providing barriers over open-topped lined equipment in 4.4.16, the equipment shall be filled with water or an ore-water slurry (pulp).

4.4.18 Rubber or plastic lined or constructed vessels, process equipment, or piping shall be clearly labeled using placards or stencils warning of hot work fire hazard.

4.4.19 The hot work permit system shall include explicit wording warning of rubber and plastic lined or constructed equipment hazards and special precautions to be taken.

4.4.20 Hot work shall not be performed in the presence of atmospheres containing flammable mixtures of gases, vapors, or liquids with air, or combustible mixtures of dust in suspension with air.

4.4.21* Hot work shall not be performed on or within containers that have contained combustible or flammable materials until such containers or tanks have been thoroughly purged and cleaned or inerted.

4.4.22 A charged water hose line or a multipurpose dry chemical portable extinguisher having a minimum nominal capacity of 9.1 kg (20 lb) shall be available at the work site before hot work is started.

4.4.23 Inspection for sparks, smoldering material, and fire shall be made during hot work operations.

4.4.24 Where hot work is performed near combustible materials that cannot be removed or protected, a trained fire watch person equipped with extinguishing devices shall be present to guard against fire during and after hot work operations.

4.4.25 Where a fire watch is required, a search of the area, including all levels or floors above and below, shall be made and the fire watch shall be maintained for a minimum of 30 minutes after completion of hot work operations to detect and extinguish smoldering combustibles.

4.4.26 Fire watchers shall be familiar with alarm location and procedures for sounding an alarm in the event of a fire.

4.4.27 Tests for methane and other flammable gases shall be made before hot work in any area where flammable gas could be present.

4.4.28 Cutting or welding shall not be allowed to begin or continue unless the concentration of flammable gas is less than 25 percent of the lower explosive limit.

4.5 Maintenance.

4.5.1 The operator shall establish a maintenance program that ensures that equipment is in proper working order.

4.5.2 All ore handling and concentrating equipment and machinery shall be maintained in accordance with the manufacturers' recommendations.

4.6 Fire Protection Equipment Inspection, Maintenance, and Testing.

4.6.1 Portable extinguishers shall be inspected, tested, and maintained in accordance with NFPA 10.

4.6.2 Any fire suppression system shall be inspected, tested, and maintained in accordance with the manufacturer's listed installation and maintenance manual or owner's manual (inspection) and the applicable NFPA standard for the type of system.

4.6.2.1 A fire suppression system, approved for use on mobile and self-propelled equipment, shall be inspected on a monthly basis in accordance with the fire suppression system manufacturer's listed installation and maintenance manual or owner's manual.

4.6.2.2 A fire suppression system, approved for use on mobile and self-propelled equipment, shall be serviced/maintained at least semiannually in accordance with the fire suppression system manufacturer's listed installation and maintenance manual.

4.7 Training.

4.7.1 All site personnel shall receive annual instruction on the different classes of fires and types of fire-fighting equipment, fire prevention, and emergency procedures to be followed during a fire.

4.7.2 All site personnel shall receive annual training in the use or operation of fire suppression and detection devices in their work areas or on the equipment they operate, supervise, or maintain.

4.7.3 All site personnel who inspect, test, and maintain a fire suppression system shall be trained to perform their intended tasks.

4.7.4 All site personnel shall receive annual instruction on emergency evacuation procedures.

4.8 Flammable and Combustible Liquid Handling and Storage.

4.8.1 Fixed, unburied flammable or combustible liquid storage tanks shall be provided with containment or drainage in accordance with NFPA 30.

4.8.2 Flammable or combustible liquids shall not be stored or processed underneath cable trays or inside cable-spreading rooms or tunnels.

4.8.3 Subsection 4.8.1 shall not apply to underground mines.

4.8.4 Ignition.

4.8.4.1 Precautions shall be taken to prevent the ignition of flammable and combustible liquid vapors.

4.8.4.2 Possible sources of ignition shall include, but are not limited to, the following:

(1) Open flames
(2) Smoking
(3) Cutting and welding
(4) Hot surfaces
(5) Frictional heat
(6) Static, electrical, and mechanical sparks
(7) Spontaneous ignition, including heat-producing chemical reactions
(8) Radiant heat

4.8.5 Where a fire risk assessment determines the need, ventilation air volume and velocity shall be designed to dilute and carry away flammable or explosive concentrations of vapors before they reach 25 percent of the lower explosive limit.

4.9 Vehicle Refueling.

4.9.1 Vehicles using liquid fuels shall be refueled only at locations designated for that purpose and from approved dispensing pumps and nozzles.

4.9.2 While fueling, vehicles, regardless of fuel type, shall be constantly attended.

4.9.3 Engines, except diesel engines, shall be shut off during refueling.

Chapter 5 Fire Risk Assessment and Risk Reduction

5.1* Fire Risk Assessment.

5.1.1 A documented fire risk assessment shall be performed for all diesel-powered underground mining equipment, all self-propelled and mobile surface mining equipment, storage and handling of flammable and combustible liquids, and surface metal mineral processing facilities.

5.1.2 Only those skilled in fire risk assessment techniques shall be permitted to conduct a fire risk assessment.

5.1.3 The fire risk assessment shall be kept on file at the mine site.

5.1.4* The fire risk assessment shall determine whether mobile or other equipment, fuel depots, and surface buildings and metal mineral processing facilities require a fixed fire suppression system.

5.1.5 The fire risk assessment shall determine whether an on-site fire fighting organization is required, based on the distance to the nearest local public fire department and response time.

5.1.6 Where required by the authority having jurisdiction, fixed fire protection systems shall be provided.

5.1.7 The fire risk assessment shall include evaluation of the risk potential for the start and spread of a fire and the generation of smoke, gases, or toxic fumes that could endanger the lives and safety of personnel or cause damage to property.

5.1.8 A separate fire risk assessment for each piece of mobile or self-propelled mining equipment — whether underground or on the surface — shall be required when variations in design, use, condition, and environment could change the fire potential.

5.1.9 If the fire risk assessment identifies unacceptable risks, further assessment shall include an evaluation of each of the following:

(1) Methods for reducing or eliminating existing hazardous fire conditions
(2) Use of detection and early fire-warning devices
(3) Use of fixed fire suppression systems
(4) Requirements for on-site fire water availability and capacity
(5) Normal and emergency means of egress from equipment or workplaces and evacuation to a safe location, such location to be determined by the fire risk assessment

(6) Compartmentalization of equipment, isolation of areas, or provision of barriers or enclosures to prevent or contain the spread of fire
(7) Availability of fire-fighting personnel and fire suppression equipment
(8) Spread of fire to combustible materials in proximity
(9) Ventilation control structures to contain or redirect products of combustion (underground mines only)
(10) Any other devices or procedures necessary to protect life and property

5.1.10 Modifications affecting the fire risk of mobile, self-propelled, or other mining equipment or buildings shall be analyzed to determine whether such modifications decrease or increase fire risks.

5.1.11 Working plans for fixed fire protection systems shall be submitted for approval to the authority having jurisdiction.

5.2 Risk Reduction.

5.2.1 Risk reduction practices shall follow the principles of minimizing ignition sources, reducing exposure of combustible materials to ignition sources, and control or suppression of fire spread.

5.2.2 For purposes of this standard, fire protection shall include fire prevention, fire detection, and fire suppression.

Chapter 6 Fire Detection and Suppression Equipment

6.1 Portable Fire Extinguishers.

6.1.1 General Requirements. All areas or process equipment in underground and surface mines and metal mineral processing plants where combustible materials are present, processed, or handled shall be provided with approved portable multipurpose fire extinguishers that comply with NFPA 10.

6.1.2 The number of such extinguishers, their type, size, and distribution shall be in accordance with NFPA 10, except that the extinguishers shall have a nominal capacity of 4.5 kg (10 lb) or greater of agent and a minimum rating of 4-A:10-B:C.

6.1.3 Extinguishers employing agents having a B:C rating shall be permitted to be used on electrical hazards.

6.1.4 At least one hand-portable fire extinguisher having a nominal capacity of 9.1 kg (20 lb) or greater and a minimum rating of 10-A:60-B:C shall be located outside of, but not more than 3 m (10 ft) from, the opening into each flammable and combustible liquid storage or dispensing area and maintenance shop.

6.1.5 Where portable fire extinguishers are provided within flammable and combustible liquid storage or dispensing areas and maintenance shops, travel distance to a portable extinguisher shall not exceed 9.1 m (30 ft).

6.2 Hand Hose Line Systems.

6.2.1 All areas or process equipment in underground and surface mines and metal mineral processing plants where combustible materials, liquids, or other fire hazards exist, as determined by the fire risk assessment, shall be provided with approved hand hose line systems.

6.2.2 Hand hose line systems shall be installed in accordance with NFPA 14, and shall be a minimum of either 38 mm (1½ in.) lined or 25 mm (1 in.) hard rubber.

6.2.3 When automatic sprinkler systems are supplied through the hand hose line standpipe system, hydraulic calculations shall be used to ensure that the piping and water supply will supply the hose and automatic sprinkler demands simultaneously.

6.2.4 Hose stations in conveyor galleries shall be provided with hoses that are of length equal to the distance between water supply connections.

6.3 Fire Detection.

6.3.1 Fire detectors shall be permitted to be used to initiate audible or visual warning, automatic actuation of a fire suppression system, equipment shutdown, or any combination thereof.

6.3.2 Fire detection systems and applicable equipment in surface mineral concentrating plants shall be installed and tested in accordance with *NFPA 72*.

6.3.3 Fire detection systems in underground mines and on surface mobile and self-propelled equipment shall be tested in accordance with *NFPA 72*.

6.3.4 Fire detectors shall be listed for their application.

6.3.5 Equipment compartment and room sizes and contours, airflow patterns, obstructions, and other characteristics of the protected area shall determine the placement, type, sensitivity, durability, and, where applicable, the number of detectors.

6.3.6 Detector testing shall not require the discharge of the fire suppression system on underground diesel-powered or surface mobile or self-propelled equipment.

6.3.7 Any equipment found deficient shall be repaired or replaced and the system retested for operation in accordance with the manufacturer's instructions.

6.3.8 The mine operator, plant superintendent, or a designee shall have a copy of the manufacturer's installation and maintenance manual or owner's manual that describes detection system operation and required maintenance.

6.4 Fire Suppression Equipment.

6.4.1 Fire suppression systems shall be designed, installed, and tested in accordance with the following NFPA standards:

(1) NFPA 11, *Standard for Low-, Medium-, and High-Expansion Foam*
(2) NFPA 12, *Standard on Carbon Dioxide Extinguishing Systems*
(3) NFPA 12A, *Standard on Halon 1301 Fire Extinguishing Systems*
(4) NFPA 13, *Standard for the Installation of Sprinkler Systems*
(5) NFPA 16, *Standard for the Installation of Foam-Water Sprinkler and Foam-Water Spray Systems*
(6) NFPA 17, *Standard for Dry Chemical Extinguishing Systems*
(7) NFPA 17A, *Standard for Wet Chemical Extinguishing Systems*
(8) NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*
(9) NFPA 750, *Standard on Water Mist Fire Protection Systems*
(10) NFPA 2001, *Standard on Clean Agent Fire Extinguishing Systems*

6.4.1.1 A pre-engineered fire suppression system shall be approved for use and shall be designed, installed, and tested in accordance with the fire suppression system manufacturer's listed installation and maintenance manual.

6.4.2 Testing shall not require the discharge of suppressant unless there is no other satisfactory manner in which the reliability and integrity of the system can be verified.

6.4.3 The mine operator, plant superintendent, or a designee shall have a copy of the manufacturer's installation and maintenance manual or owner's manual that describes suppression system operation, required maintenance, and recharging.

6.4.4 Where inadvertent discharge of the fire suppression system during servicing could result in injury to personnel, provisions shall be made to safeguard against accidental actuation of the system.

Chapter 7 Fire Protection for Diesel-Powered Equipment in Underground Mines

7.1 Equipment Modification.

7.1.1* All diesel-powered mining equipment shall be analyzed to determine whether fire risks can be reduced through equipment modification.

7.1.2* Modifications affecting the fire risk of diesel-powered mining equipment shall be analyzed to determine whether such modifications decrease or increase the fire risk.

7.2 Equipment Inspection and Maintenance. Hydraulic fluid, coolant, lubrication and fuel lines, electrical wiring, mechanical components, and fire prevention devices shall be inspected and maintained in accordance with the manufacturers' recommendations.

7.3 Portable Fire Extinguishers.

7.3.1 All self-propelled, diesel-powered underground equipment shall be equipped with at least one portable, multipurpose (ABC) dry chemical extinguisher having a nominal capacity of 4.6 kg (10 lb) of extinguishing agent and a minimum rating of 4-A:10-B:C.

7.3.2 The risk assessment shall determine whether larger or additional extinguishers are needed.

7.4 Fixed Suppression Systems. Diesel-powered equipment shall be protected by a fixed fire suppression system to suppress the largest anticipated fires in the protected areas, and that system shall have the following characteristics:

(1) Be listed or approved for the purpose
(2) Be automatically actuated by a fire detection system
(3)*Have one manual actuator in the operator's compartment and at least one additional actuator accessible from the ground
(4) Be provided with an agent container and a network of agent distribution hoses or pipes with discharge nozzles
(5) Be provided with discharge nozzle blowoff caps or other suitable devices or materials to prevent the entrance of moisture, dirt, or other material into the piping
(6) Have all system components secured and protected against damage, including abrasion and corrosion
(7) Be installed so that the system actuation causes shutdown of the protected equipment
(8) Permit up to a 30-second agent discharge delay
(9) Include a standby source of power if electrical power is the only means of actuation
(10) Have an installation and maintenance manual or owner's manual

7.4.1 Post-installation testing shall be in accordance with the manufacturer's or designer's recommendations.

7.4.2 Testing shall not require the discharge of suppressant unless there is no other satisfactory manner in which the reliability and integrity of the system can be verified.

Chapter 8 Transfer of Flammable or Combustible Liquids in Underground Mines

8.1 Fire Risk Assessment. The fire risk assessment for surface flammable or combustible liquid storage areas located near underground mines shall include the following:

(1) The potential for the generation of smoke, gases, or toxic fumes that could contaminate the mine intake air
(2) The topography and relative elevation of storage tanks and mine openings
(3) Air currents
(4) Vegetation

8.2 Proximity of Surface Flammable and Combustible Liquid Storage to Underground Openings.

8.2.1 Surface flammable or combustible liquid storage areas shall be located away from any mine opening to prevent contamination of mine intake air, but in no case shall they be closer than 30.5 m (100 ft) unless the boreholes are drilled specifically for the transfer of combustible liquids to the underground mine.

8.2.2 Drainage from flammable or combustible liquid storage areas shall be designed and maintained to prevent liquid flow toward any mine opening.

8.3 Surface-to-Underground Transfer.

8.3.1 Flammable or combustible liquid shall be permitted to be transferred into the mine by pipeline, portable tank, closed container, or safety can.

8.3.2 Persons shall not be transported on conveyances with flammable or combustible liquids unless the items are secured or are small and can be carried safely by hand.

8.3.3 Where flammable or combustible liquid is transferred into the mine, it shall be transferred directly to a storage area or a location where it will be used.

8.3.4* Pipeline systems used for flammable or combustible liquid transfer shall be permitted to be either wet or dry pipe installations.

8.3.5 Piping, valves, and fittings used for flammable or combustible liquid transfer shall be suitable for the expected working pressures and structural stresses.

8.3.6 Piping, valve, and fitting burst strengths shall be at least four times the static pressure.

8.3.7 The mechanical and thermal stresses of the pipeline caused by exposure to fire shall be considered in the selection of components and the design of the pipeline system.

8.3.8 A manual shutoff valve shall be installed in the pipeline at the surface storage tank and at the point of underground discharge.

8.3.9 An additional shutoff valve shall be installed in each branch line where the branch line joins the main line.

8.3.10 The pipeline system shall be guarded by location or other acceptable practice so as to be protected against physical damage.

8.3.11 Flammable or combustible liquid pipeline transfer systems shall be maintained to function as designed.

8.3.12 A fire risk assessment shall be conducted for the location(s) intended for installation of flammable or combustible liquid pipeline systems.

8.4 Underground Transfer.

8.4.1 Persons shall not be transported on conveyances with flammable or combustible liquids unless the items can be carried by hand.

8.4.2 Flammable or combustible liquid containers or tanks loaded on rail or trackless vehicles shall be secured against shifting and damage during transit.

8.4.3 Flammable or combustible liquid containers or tanks shall be at least 305 mm (12 in.) below energized trolley wires or protected from contacting the wire by insulation while being transported by trolley wire-powered systems.

8.4.4 Vehicles transporting flammable or combustible liquids shall be kept clear of accumulations of oil, grease, and other combustible material.

8.4.5 Vehicles transporting flammable or combustible liquids shall not be stored under an energized trolley wire.

8.4.6 Unless in a single tank or container, the quantity of flammable or combustible liquids in containers or tanks off-loaded from transport vehicles and stored in an operating area shall not exceed a three-day supply for equipment normally operating in that area.

Chapter 9 Flammable Liquid Storage in Underground Mines

9.1* General.

9.1.1* Electrical equipment in large flammable liquid storage areas shall be Class I, Division 1, as specified in *NFPA 70*, or shall be classified as "permissible" electrical equipment.

9.1.2 Flammable liquids in storage shall be kept in closed containers.

9.1.3 Flammable liquids shall be permitted to be used only where there are no open flames or other sources of ignition within the possible path of vapor travel in flammable concentrations.

9.1.4 Flammable liquid containers shall be returned to a flammable liquid storage area after use.

9.1.5 Other than Class IA liquids in aerosol cans, flammable liquids with flash points below −18°C (0°F), such as gasoline, shall not be permitted.

9.2 Flammable Liquid Containers.

9.2.1 Safety cans or containers for flammable liquids authorized by the U.S. Department of Transportation (DOT) shall be acceptable as storage containers.

9.2.2 Containers for flammable liquids shall conform to the capacity limitations specified in Table 9.2.2.

9.2.3 All flammable liquid containers shall be labeled clearly with the word "flammable."

9.2.4 Flammable liquid containers shall be stored to prevent overturning or toppling.

9.3 Small Flammable Liquid Storage Areas.

9.3.1 Small flammable liquid storage areas shall be separated from other small flammable or combustible liquid storage areas by at least 15.24 m (50 ft) or from large flammable liquid storage areas by a distance of at least 30.5 m (100 ft), or they shall be separated by unexcavated rock or masonry bulkheads.

9.3.2 Storage of flammable liquids in small flammable liquid storage areas shall be in cabinets specifically designed and constructed for such purpose.

9.4 Large Flammable Liquid Storage Areas.

9.4.1 The total aggregate quantity of flammable liquids to be stored in any one storage area shall not exceed 624 L (165 gal).

9.4.2 Large flammable liquid storage areas shall be separated from other flammable or combustible liquid storage areas by at least 30.5 m (100 ft) or separated by an unexcavated rock or masonry bulkhead and shall be located a minimum of 30.5 m (100 ft) from any shaft station or explosives magazine or electrical substation and transformers.

9.4.2.1* Electrical equipment within 15.2 m (50 ft) from the storage area shall be Class I, Division 1, as specified in *NFPA 70*, or shall be classified as "permissible" electrical equipment.

9.4.2.2 Large flammable liquid storage areas shall be located a minimum of 30.5 m (100 ft) from any working face and out of the line of sight of blasting, or they shall be located a minimum of 152.4 m (500 ft) within the line of sight of any working face.

9.4.2.3 Large flammable liquid storage areas shall not be constructed in an area bounded at any point by self-igniting rock.

9.4.3 Large flammable liquid storage areas shall be enclosed and of noncombustible construction.

9.4.3.1 The enclosure shall be tightly sealed and have a minimum 2-hour fire resistance rating.

9.4.3.2 Each opening into a large flammable liquid storage area shall be limited to a maximum area of 9.2 m^2 (100 ft^2).

9.4.3.3 Openings shall be equipped with self-closing fire doors with a minimum 1½-hour fire resistance rating.

9.4.3.4 The entire storage area below the sill shall be capable of containing the total amount of flammable liquids stored, or means shall be provided to remove the spilled flammable liquid safely.

9.4.3.5 Large flammable liquid storage areas shall have exhaust directed to an exhaust ventilating system with air movement with a velocity to maintain flammable vapors at less than 25 percent of the lower explosive limit.

9.4.4 Noncombustible storage cabinets meeting the requirements specified in NFPA 30, Section 9.5, shall be considered as complying with the construction requirements for large flammable liquid storage areas.

Table 9.2.2 Maximum Allowable Size of Containers for Flammable Liquids

	Class IA		Class IB		Class IC	
Container Type	**L**	**gal**	**L**	**gal**	**L**	**gal**
Original metal containers (other than DOT containers) or approved plastic containers	3.79	1	18.93	5	18.93	5
Safety cans	7.57	2	18.93	5	18.93	5
Containers, other than safety cans, complying with 9.2.1		Not allowed	227.12	60	227.12	60

9.4.4.1 Combustible rock shall be covered with noncombustible material, such as gunite, shotcrete, or preformed masonry units.

9.5 Dispensing Flammable Liquids.

9.5.1 Flammable liquids shall be drawn from or transferred into containers within a storage area using only the following methods:

(1) From safety cans
(2) From a container by means of a device drawn through an opening in the top of the container
(3) By gravity through a listed or approved self-closing valve or self-closing faucet

9.5.2 Transfer.

9.5.2.1 Transfer of flammable liquids by means of pressurizing a container with air shall be prohibited.

9.5.2.2 Transfer of flammable liquids by pressure of inert gas shall be permitted only if controls, including pressure-relief devices, are provided to limit the pressure so it cannot exceed the design pressure of the container.

9.5.3 Where electrically powered pumps are used to transfer flammable liquids, a clearly identified and accessible switch or circuit breaker shall be provided at a suitably remote location, as determined by a fire risk assessment, to shut off the power to all dispensing and pumping devices in the event of an emergency.

9.5.4 Where flammable liquids are dispensed from containers, the containers shall be provided with approved vents, bonding, and flame arresters.

9.5.5 At least one portable fire extinguisher having a nominal capacity of 9.1 kg (20 lb) or greater with a minimum rating of 4-A:60-B:C shall be located not more than 9.1 m (30 ft) from any area where flammable liquid is dispensed.

Chapter 10 Combustible Liquid Storage in Underground Mines

10.1 General.

10.1.1 Chapter 10 shall apply to the storage and handling of combustible liquids in containers, portable tanks, and tanks intended for fixed installations.

10.1.2 Combustible liquids in use shall not be covered in this chapter.

10.1.3 Combustible liquids in approved tanks or containers meeting the following requirements shall not require any special consideration and shall be permitted to be exempt from the requirements for storage areas if the containers or tanks are located at least 15.24 m (50 ft) from a working face, explosives magazines, electrical substations, shafts, other exempt containers or tanks, or any storage area and if they are located out of the line of sight of blasting and out of the way of vehicular traffic:

(1) Class II combustible liquids stored in containers meeting the requirements of this chapter and not exceeding an aggregate of 227 L (60 gal) in any single location
(2) Class III combustible liquids stored in containers or approved tanks as specified in this chapter and not exceeding an aggregate of 2498 L (660 gal) in any single location

10.1.4 Ventilation shall be provided to prevent the accumulation of ignitible vapors.

10.2 Combustible Liquid Containers and Tanks.

10.2.1 Shipping containers and portable tanks of combustible liquids authorized by the U.S. Department of Transportation shall be acceptable as storage containers.

10.2.1.1 Shipping containers larger than 18.9 L (5 gal) shall be provided with vacuum and pressure relief.

10.2.1.2 Containers and portable tanks for combustible liquids shall conform to the capacity limitations defined in Chapter 3.

10.2.2 Combustible liquid storage tanks intended for fixed installation and engineered portable tanks shall be of materials compatible with the liquid stored and shall be designed and built in accordance with good engineering practices.

10.3* Atmospheric Tanks. Atmospheric tanks shall not be used for storage of a combustible liquid at a temperature above its boiling point.

10.4* Low-Pressure Tanks. The operating pressure of the tanks shall not exceed the design working pressure.

10.5* Pressure Vessels. The operating pressure of the vessel shall not exceed the design working pressure.

10.6 Venting Atmospheric and Low-Pressure Combustible Liquid Storage Tanks.

10.6.1 Storage tanks shall be vented to prevent the development of a vacuum or pressure that could distort the shell or roof of the tank as a result of filling or emptying and atmospheric temperature changes.

10.6.2 Protection also shall be provided to prevent overpressure from any filling source exceeding the design pressure of the tank.

10.6.2.1* Vents shall be at least as large as the filling or withdrawing lines but not less than 32 mm (1¼ in.) nominal inside diameter.

10.6.3 If more than one fill or withdraw line can be used simultaneously, the vent capacity shall be based on the maximum anticipated simultaneous flow.

10.6.3.1 Vent pipes shall be constructed to drain toward the tank without sags or traps to collect liquid.

10.7 Additional Considerations.

10.7.1 Connections for all tank openings shall be liquidtight.

10.7.2 Each connection to a tank through which liquid normally can flow shall be provided with a valve located at the flange nearest the shell of the tank.

10.7.3 Tanks containing combustible liquids shall be provided with a means, such as a remote manual or automatically actuated valve, for quick cutoff of flow in the event of fire in the vicinity of the tank.

10.7.4 Openings for manual gauging, if independent of the fill pipe, shall be kept closed when not gauging.

10.7.5 Each such opening for any liquid shall be protected against liquid overflow and possible vapor release by means of a spring-loaded check valve or other device.

10.7.6 Substitutes for manual gauging shall be permitted.

10.8 Small Combustible Liquid Storage Areas.

10.8.1 Combustible liquid storage areas shall be located a minimum of 30.5 m (100 ft) from explosives magazines, electrical substations, working faces, or other combustible liquid storage areas or shall be separated by unexcavated rock or masonry bulkheads.

10.8.2 The storage area, unless equipped with an approved fire protection system, shall be located a minimum of 30.5 m (100 ft) from any shaft station.

10.8.3 A combustible liquid storage area shall be recessed or otherwise located and protected from accidental damage by mobile equipment or blasting.

10.8.4 Combustible liquid storage areas shall not be constructed in an area bounded at any point by self-igniting ore.

10.8.5 Where combustible liquid storage areas are constructed of combustible materials or are located where there is rock capable of self-propagating combustion, the material or rock shall be covered with noncombustible material such as gunite, shotcrete, or preformed masonry units.

10.8.6 Where tanks are used, a means shall be provided to confine within or remove from the combustible liquid storage area the contents of the largest tank in the event of a tank rupture.

10.9 Large Combustible Liquid Storage Areas.

10.9.1 The total quantity of combustible liquids in storage tanks intended for fixed installation shall not be restricted.

10.9.2 In areas not protected by automatic fire suppression systems, the total quantity of combustible liquids in containers and portable tanks shall be restricted in accordance with Table 10.9.2, but in no case shall the aggregate quantity exceed 190,000 L (50,000 gal) in any single storage area.

Table 10.9.2 Unprotected Storage of Combustible Liquids in Containers and Portable Tanks

	Maximum Pile Height		Maximum Quantity per Pile		Maximum Total Quantity	
Class	m	ft	L	gal	L	gal
Container Storage						
II	2.1	7	7,570	2,000	15,100	4,000
IIIA	2.1	7	26,500	7,000	53,000	14,000
IIIB	2.1	7	26,500	7,000	106,000	28,000
Portable Tank Storage						
II	3.0	10	11,360	3,000	22,700	6,000
IIIA	3.0	10	41,640	11,000	83,300	22,000
IIIB	3.0	10	41,640	11,000	166,600	44,000

10.9.3 The use of racks shall not be permitted in unprotected areas.

10.9.3.1 Where combustible liquid storage areas are protected by automatic fire suppression systems, the total quantity of combustible liquids in containers and portable tanks shall not be restricted.

10.9.4 Within a combustible liquid storage area, the quantity stored in a single pile shall be in accordance with Table 10.9.4.

Table 10.9.4 Storage Arrangements for Protected Palletized or Solid Pile Storage of Combustible Liquids in Containers and Portable Tanks

	Maximum Storage Height				Maximum Quantity per Pile			
	Containers		Portable Tanks		Containers		Portable Tanks	
Class	m	ft	m	ft	L	gal	L	gal
II	2.1	7	3.0	10	28,400	7,500	75,700	20,000
III	3.0	10	4.6	15	37,850	10,000	75,700	20,000

10.9.4.1 For mixed storage of Class II and Class III liquids in a single pile or rack, the maximum quantity and maximum height in that pile or rack shall be as specified for Class II liquids *(see Table 10.9.4 and Table 10.9.5.1)*, as applicable.

10.9.5 Individual piles *(see Table 10.9.2 and Table 10.9.4)* shall be arranged so that piles are separated from each other by at least 1.2 m (4 ft).

10.9.5.1 Where racks are used, the heights and quantities per rack shall be in accordance with Table 10.9.5.1.

Table 10.9.5.1 Storage Arrangements for Protected Rack Storage of Combustible Liquids in Containers

		Maximum Storage Height		Maximum Quantity per Rack	
Class	Rack Type	m	ft	L	gal
II	Double row or single row	4.6	15	34,000	9,000
III	Multirow, double row, or single row	6.1	20	90,850	24,000

10.9.6 Single-row or double-row rack storage *(see Table 10.9.5.1)* shall be separated by minimum 2.4 m (8 ft) aisles from other rows of rack storage or other pile storage.

10.9.7 Empty or idle combustible pallet storage within the combustible liquid storage area shall be limited to a maximum pile size of 23.2 m^2 (250 ft^2) and a maximum storage height of 2.1 m (7 ft).

10.9.8 Idle pallet storage shall be separated from combustible liquids by at least 1.2 m (4 ft).

10.9.8.1 Combustible liquid storage areas shall be located a minimum of 30.5 m (100 ft) from explosives magazines or electrical substations.

10.9.9 Combustible liquid storage areas shall be located a minimum of 30.5 m (100 ft) from any shaft station, unless equipped with an approved fire protection system.

10.9.10 Combustible liquid storage areas shall be located a minimum of 30.5 m (100 ft) from any working face and out of the line of sight of blasting, or they shall be located a minimum of 152 m (500 ft) within the line of sight of any working face to avoid damage from fly rock.

10.9.11 Combustible liquid storage areas shall be separated from other flammable or combustible liquid storage areas by a distance of at least 30.5 m (100 ft), or they shall be separated by unexcavated rock or masonry bulkheads.

10.9.12 The masonry bulkhead shall have a minimum thickness of 102 mm (4 in.) of block or 51 mm (2 in.) of reinforced gunite.

10.9.12.1 Combustible liquid storage areas that are enclosed shall be built of noncombustible materials.

10.9.13 Combustible rock within all large combustible liquid storage areas shall be covered with noncombustible material such as gunite, shotcrete, or preformed masonry.

10.9.13.1 If enclosed, each opening into a combustible liquid storage area shall be equipped with a self-closing metal door.

10.9.14 Bulkheads, if used, shall be sealed tightly and shall be built or covered with noncombustible materials.

10.9.14.1 No storage areas shall be constructed in a location bounded at any point by self-igniting ore.

10.9.15* Tanks shall rest on the ground or on foundations made of concrete, masonry, piling, or steel.

10.9.16 Tank foundations shall be designed to minimize the possibility of uneven settling of the tank and to minimize corrosion in any part of the tank resting on the foundation.

10.9.16.1 The entire combustible liquid storage area below the door sill shall be capable of containing the total amount of combustible liquid, or means shall be provided to remove the combustible liquid.

10.9.17 All piping, valves, and fittings shall be designed for the expected working pressures and structural stresses.

10.9.18 Combustible liquid storage areas not buried or equipped with automatic fire suppression systems shall have exhaust directed to an exhaust ventilating system.

10.10* Dispensing Combustible Liquids.

10.10.1 Dispensing combustible liquid from containers or tanks shall be permitted to be accomplished by transfer pump or gravity flow.

10.10.2 Means shall be provided to control the flow and prevent leakage and accidental discharge.

10.10.2.1 Combustible liquids shall be permitted to be dispensed through the application of positive pressure to containers or tanks only if they are certified as pressure vessels.

10.10.3 Manual dispensing valves, if used, shall be of the self-closing type.

10.10.3.1 Where electrically powered pumps are used to dispense combustible liquids, a clearly identified and accessible switch or circuit breaker shall be provided at a suitably remote location, as determined by a fire risk assessment, to shut off the power to all dispensing and pumping devices in the event of an emergency.

10.10.4 Dispensing nozzles shall be of the self-closing type without a latch-open device.

10.10.5 Combustible liquids shall not be dispensed within 15.24 m (50 ft) of cutting or welding operations.

10.10.6 At least one portable fire extinguisher having a nominal capacity of 9.1 kg (20 lb) with a minimum rating of 4-A:60-B:C shall be located not more than 9.1 m (30 ft) from any area where combustible liquid is dispensed.

10.10.7 Spillage shall be cleaned up.

Chapter 11 Fire Suppression for Flammable or Combustible Liquid Storage Areas in Underground Mines

11.1 Portable Fire Extinguishers.

11.1.1 At least one hand portable fire extinguisher having a nominal capacity of 9.1 kg (20 lb) with a minimum rating of 4-A:60-B:C shall be located outside of, but not more than 3.0 m (10 ft) from, the opening into each storage area.

11.1.2 The installation of manual or automatic fire suppression systems shall not exempt the requirements for a portable fire extinguisher.

11.1.2.1 Where portable fire extinguishers are provided within storage areas, travel distance to a portable extinguisher shall not exceed 9.1 m (30 ft).

11.2 Hand Hose Line Systems. Hand hose lines designated for fire fighting and accessible to flammable and combustible storage areas shall be equipped to discharge a foam-water solution and shall be in accordance with NFPA 11.

11.3 Fire Suppression Systems.

11.3.1* Where provided, automatic sprinkler systems installed for the protection of flammable liquid or diesel fuel storage areas shall be of the foam-water type.

11.3.2 Where provided, automatic sprinkler systems used for the protection of other underground mine combustible liquid storage areas shall be installed in accordance with NFPA 13.

11.3.3 Where the fire suppression requirements of this standard are met by means other than an automatic sprinkler system but an automatic sprinkler system is installed to supplement such means, the water supply provisions for automatic sprinkler systems of NFPA 13 shall not be required.

11.3.4 Fire suppression systems other than automatic foam-water sprinkler systems in underground mines shall be in accordance with NFPA 11, NFPA 12, NFPA 12A, NFPA 16, NFPA 17, and NFPA 2001.

Chapter 12 Fire Prevention and Fire Protection of Surface Mining Equipment

12.1 General. This chapter shall cover haul trucks, front end loaders, bulldozers, graders, scrapers, blast hole drills, shovels, hydraulic and bucket wheel excavators, draglines, and other mobile and self-propelled equipment.

12.2* Fire Prevention. Risk reduction practices shall follow the principles of minimizing ignition sources and reducing exposure of combustible materials to ignition sources.

12.2.1 Housekeeping.

12.2.1.1 Spills, leaks, excess lubricants, and combustible materials such as oil-soaked wastes, rubbish, and accumulations of environmental debris shall not be allowed to accumulate in quantities that could create a fire hazard.

12.2.1.2 Approved metal receptacles shall be provided where oil-soaked wastes or rubbish are not immediately removed to a safe place for disposal.

12.2.1.3 The storage and handling of flammable or combustible liquids on or within equipment shall be in accordance with Chapter 17 of NFPA 30.

12.2.1.4 Access to fire protection equipment on mining equipment shall be kept clear of obstructions.

12.2.2 Inspection and Maintenance of Equipment. Hydraulic, coolant, lubrication and fuel lines, electrical wiring, and fire prevention devices shall be inspected and maintained in accordance with the manufacturers' recommendations.

12.2.3 Flammable and Combustible Liquid Storage on Equipment. Flammable and combustible liquid storage and usage shall be in accordance with Section 4.8.

12.2.4 Compressed Gas Storage and Usage. Compressed gas storage and usage shall be in accordance with Section 4.4.

12.3 Fire Protection.

12.3.1 Fire protection for the purposes of this standard shall be defined in the broad sense to include fire detection and fire suppression.

12.3.2 Fire suppression systems shall include dry chemical, wet chemical, gaseous, water mist, foam, or sprinklers.

12.3.3 Fire suppression systems and fire alarm systems shall be installed in accordance with applicable NFPA standards.

12.3.4 Portable Fire Extinguishers.

12.3.4.1* All self-propelled and mobile diesel and electrical equipment shall be equipped with at least one listed portable multipurpose (ABC) dry chemical extinguisher having a minimum rating of 4-A:60-B:C and a nominal capacity of 4.6 kg (10 lb) or greater of extinguishing agent.

12.3.4.2 The fire risk assessment shall be used to determine whether larger or additional extinguishers are needed.

12.3.4.3 The fire-extinguishing agent applied by hand-portable extinguishers to hazards involving energized electrical equipment shall be nonconductive.

12.3.4.4 Portable fire extinguishers shall be maintained in accordance with NFPA 10 and kept in their designated places at all times.

12.3.4.5 Portable fire extinguishers shall be located on each vehicle and shall be accessible.

12.3.4.6 In areas where obstruction to visual observation cannot be completely avoided, visible markings shall be provided to indicate the location of the portable fire extinguishers.

12.3.4.7 Extinguishers installed under conditions where they can be subject to physical damage shall be guarded to protect against damage.

12.3.4.8 The installation of an automatic or manually operated fire suppression system shall not eliminate the portable fire extinguisher requirement.

12.3.4.9 Portable fire extinguishers shall be inspected, maintained, and recharged as specified in NFPA 10, Chapter 7, and the following:

(1) Portable fire extinguishers shall be inspected visually at least monthly.
(2) The visual inspection shall ensure the following:
    (a) The extinguisher is in its designated place.
    (b) The tamper seals are intact.
    (c) The extinguisher gauge is in the operable range (if the extinguisher is the stored-pressure type).
    (d) There is no obvious physical damage or condition that will prevent proper operation.
(3) Extinguishers found to be defective or deficient by visual inspection shall be replaced.
(4) Extinguishers shall be subjected to a maintenance examination at least once every year.
(5) Maintenance procedures shall include a thorough examination of the extinguishers, including mechanical parts, extinguishing agent, and expellant.

(6) Any troubles or impairments shall be corrected.
(7) All extinguishers shall be recharged after use in accordance with the manufacturer's recommendations.
(8)*Each extinguisher shall have a permanent tag attached on which the inspection date shall be recorded.

12.3.4.10 Portable extinguishers shall be tested hydrostatically at intervals not exceeding those specified in NFPA 10, Chapter 8.

12.3.5 Draglines, Bucket Wheel Excavators, Electric Shovels, and Hydraulic/Electric Excavators.

12.3.5.1 Center Pin/Collector Ring Area.

12.3.5.1.1 An automatic fire suppression system shall be installed in the center pin/collector ring area. If an electrical spark cannot communicate from the collector ring (e.g., a sealed ring) to the grease around the center pin, a fire suppression system is not required.

12.3.5.1.2 An automatic fire suppression system shall be installed in the ring gear area.

12.3.5.1.3 An audible and visual suppression system alarm shall be transmitted to the operator's cab.

12.3.5.1.4 A manual actuator shall be provided just outside the center pin/collector ring area.

12.3.5.2 Hydraulics.

12.3.5.2.1* An automatic fire suppression system shall be installed to protect the hydraulic pump(s), hydraulic control valves, and associated lines and equipment in the hydraulic pump area and other areas where fires can spread.

12.3.5.2.2* The system shall send audible and visual alarms to the operator's cab.

12.3.5.2.3 A manual actuator shall be located just outside the hydraulic compartment area.

12.3.5.3 Lube Oil Pumping and Storage.

12.3.5.3.1* Automatic lube oil systems that are located in a segregated room shall be provided with an automatic fire suppression system.

12.3.5.3.2 The system shall send an audible and visual alarm to the operator's cab.

12.3.5.3.3 A manual actuator shall be located just outside the lube oil room.

12.3.5.3.4 Lube oil rooms shall have automatic door closers or shall have the door interlocked to shut upon actuation of the fire suppression system.

12.3.5.4 Transformers.

12.3.5.4.1 Oil-filled transformers located in the tail section, enclosed rooms, or other inaccessible locations shall be provided with an automatic fire suppression system.

12.3.5.4.1.1 The system shall transmit an audible and visual alarm to the operator's cab.

12.3.5.4.1.2 A manual actuator shall be located just outside the transformer area.

12.3.5.4.2* Transformers located in areas other than those listed in 12.3.5.4.1 shall be protected with a Class B:C, minimum 45.4 kg (100 lb) fire extinguisher.

12.3.5.4.3 Oil analysis, including dissolved gas, shall be conducted on combustible oil-filled transformers based upon manufacturer's recommendations or the ANSI/NETA MTS, *Standard for Maintenance Testing Specifications for Electrical Power Distribution Equipment and Systems*, whichever is more stringent.

12.3.5.4.4 Thermographic scanning shall be performed on transformers on an annual basis.

12.3.5.5 Electrical Room or Cabinet.

12.3.5.5.1 Enclosed electrical rooms shall be protected with a total flooding gaseous extinguishing agent or equivalent fire suppression system.

12.3.5.5.1.1 The gaseous extinguishing system shall be installed in accordance with NFPA 2001.

12.3.5.5.1.2 The gaseous extinguishing system shall be actuated by a smoke, ultraviolet/infrared (UV/IR), or heat detector system and send an audible and visual alarm to the operator's cab.

12.3.5.5.1.3 The ventilation system shall be interlocked to the gaseous extinguishing system to shut down upon first detection.

12.3.5.5.1.4 The room shall be sealed to maintain the design gaseous extinguishing concentration.

12.3.5.5.2 Electrical rooms shall be maintained at a positive pressure to reduce the chances of dust entering the room.

12.3.5.5.3 Electrical cabinets shall be protected with a gaseous fire suppression system.

12.3.5.5.3.1 The system shall be installed in accordance with NFPA 2001.

12.3.5.5.3.2 The system shall be actuated by a smoke, UV/IR, or heat detector system and send an audible and visual alarm to the operator's cab.

12.3.5.6 Manual Extinguishing Equipment.

12.3.5.6.1 Minimum 45.4 kg (100 lb) ABC-type extinguishers shall be accessible to persons on the main deck of the dragline.

12.3.5.6.2 The location and number of extinguishers shall be determined by what is practical for the machine.

12.3.6 Hydraulic/Diesel Excavators.

12.3.6.1 An automatic fire suppression system shall be provided to protect the engine compartment, hydraulic pumps, and associated equipment.

12.3.6.1.1* For diesel-powered generators with hydraulic systems containing more than 567.8 L (150 gal) in the lines, a dual agent system shall be provided.

12.3.6.1.2 A manual actuator shall be located in the operator's cab and at the means of egress from the machine.

12.3.6.2 The machine shall be interlocked to shut down upon discharge of the extinguishing system.

12.3.6.3 A means shall be provided to automatically relieve the hydraulic pressure upon discharge of the extinguishing system.

12.3.6.4 Adequate fire resistance shielding shall be provided between the hydraulic hoses and the turbocharger and engine manifold to prevent hydraulic fluid from being sprayed on hot mechanical parts.

12.3.6.5 The fire detection electrical wiring within fire hazard areas, such as battery compartments, engine compartments, and so forth, shall be outfitted with a fire-resistant sleeve.

12.3.6.6 Fire suppression system manual actuation lines shall not be routed near high heat surfaces and shall not be routed within fire hazard areas unless fitted with fire-resistant sleeves.

12.3.7 Mobile Equipment.

12.3.7.1 Fire Protection. Portable extinguishers installed on mobile mining equipment, including but not limited to mobile generators and compressors, shall have a minimum rating of 2-A:10-B:C and a nominal capacity of 2.3 kg (5 lb) of extinguishing agent.

12.3.8 Self-Propelled Equipment.

12.3.8.1 Portable Fire Extinguishers.

12.3.8.1.1* All self-propelled surface mining equipment, including but not limited to bulldozers, front-end loaders, haulage trucks, cranes, graders, scrapers, draglines, drills, shovels, and diesel and electrical equipment, shall be equipped with at least one listed, portable, multipurpose (ABC), dry-chemical extinguisher having a nominal capacity of 4.5 kg (10 lb) or greater of agent.

12.3.8.1.2 Portable extinguishers installed on small units of self-propelled mining equipment, including but not limited to miniature loaders and individual personnel transports, shall have a minimum rating of 2-A:10-B:C and a nominal capacity of 2.3 kg (5 lb) of extinguishing agent.

12.3.8.2 Fire Detection.

12.3.8.2.1 Fire detectors shall be permitted to be used to initiate audible or visual warning, automatic actuation of a fire suppression system, or equipment shutdown.

12.3.8.2.2 Fire detectors shall be tested and listed for the application.

12.3.8.2.3 Compartment sizes and contours, airflow patterns, obstructions, and other characteristics of the protected area shall determine the placement, type, sensitivity, durability, and, where applicable, number of detectors.

12.3.8.2.4 All fire detection systems and applicable equipment shall be tested after installation in accordance with *NFPA 72* and fire suppression systems standards.

12.3.8.2.4.1 It shall not be necessary for testing to require the discharge of any associated fire suppression system.

12.3.8.2.5* At least every 6 months, all fire detection systems, including alarms, shutdowns, and other associated equipment, shall be thoroughly examined and checked for proper operation in accordance with the manufacturer's recommendations.

12.3.8.2.5.1 Any equipment found deficient shall be repaired or replaced, and the system retested for operation in accordance with the manufacturer's instructions.

12.3.8.2.6 Between the maintenance examinations or tests, the detection system shall be inspected visually, in accordance with an approved schedule necessitated by conditions as determined by the mine operator.

12.3.8.3 Fixed Suppression Systems.

12.3.8.3.1 Haul trucks with a capacity of over 77 metric tons (85 tons) shall have a fixed fire suppression system protecting the engine compartment and hydraulic pump and other hazard areas.

12.3.8.3.2* Other large mining equipment such as but not limited to bulldozers, endloaders, drills, graders, and scrapers shall have a fixed fire suppression system protecting the engine compartment and hydraulic pump and other hazard areas.

12.3.8.3.3 Mining equipment requiring a fire suppression system shall be protected by a system to suppress potential fires in the protected areas and shall comply with the following:

(1) The fire suppression system shall be listed or approved for the purpose.
(2) Where installed, the equipment shall be located or guarded so as to be protected against physical damage.
(3) Fire suppression systems shall be automatically actuated.
(4)*Automatically actuated systems shall also have a manual actuator capable of being activated from the operator's compartment or other location.
(5) Agent distribution hose or pipe shall be secured and protected against damage, including abrasion and corrosion.
(6) Except for automatic sprinkler systems, discharge nozzles shall be protected against entrance of environmental debris, including moisture, dust, dirt, or insects, by blowoff caps or other similar devices or materials.
(7) Except for automatic sprinkler systems, the nozzle cover shall open or blow off upon discharge of the system.
(8) The automatic fire suppression system shall be installed so that system actuation causes shutdown of the protected equipment.
(9) Up to a 30-second delay shall be included in the design of the interlock system for the operator to maintain control of the equipment.

12.3.8.3.4 A standby source of power shall be provided where electrical power is the only means of fire suppression system actuation.

12.3.8.3.5 All fire suppression equipment and systems shall be tested after installation in accordance with the manufacturer's or designer's recommendations.

12.3.8.3.5.1 Testing shall not require the discharge of suppressant unless there is no other manner in which the reliability and integrity of the system can be verified.

12.3.8.3.6 An installation-and-maintenance or owner's manual that describes system operation and maintenance requirements shall be provided for all fire suppression equipment.

12.3.8.3.7* In accordance with the manufacturers' or designers' recommended inspection and maintenance procedures and schedules, but not to exceed every 6 months, all fire suppression systems, including alarms, shutdowns, and other associated equipment, shall be thoroughly examined and checked for proper operation by trained and competent personnel.

12.3.8.3.7.1 Any equipment found deficient shall be repaired or replaced, and the system retested for proper operation.

12.3.8.3.7.2 Between regular maintenance examinations or tests, the system shall be inspected visually, in accordance with the manufacturer's or designer's recommended schedule.

12.3.8.3.7.3 Testing shall be in accordance with the applicable NFPA standards.

12.3.8.3.8 Fire suppression systems shall be maintained in operating condition at all times.

12.3.8.3.9 Use, impairment, and restoration of the system shall be reported to the mine operator.

12.3.8.3.10 All persons who can be expected to inspect, test, maintain, or operate a fire suppression system shall be trained to perform their intended tasks.

12.3.8.3.11 Where inadvertent discharge of the fire suppression system during servicing could result in injury to personnel, provisions shall be made to safeguard against accidental actuation of the system.

12.3.8.3.12 All operators, supervisors, and maintenance personnel of self-propelled and mobile equipment shall be trained in the use of fire suppression equipment.

Chapter 13 Fire Protection of Surface Metal Mineral Processing Plants

13.1 General. Chapter 13 shall include the following:

(1) Mill (concentrator) processing buildings
(2) Crushers and crushing buildings
(3) Conveyor systems
(4) Combustible and flammable liquids mixing buildings and tank farms
(5) Other ore processing facilities such as filter rooms, process pump houses, and thickeners
(6) Electrical substations, transformers, control rooms, cable-spreading rooms and tunnels, and motor control center (MCC) rooms
(7) Offices, shops, laboratories, warehouses, fuel depots, maintenance garages, and other ancillary nonproduction buildings on the site of and supporting the operation of the mineral processing plant

13.2 Emergency Response and Manual Fire Fighting.

13.2.1 Based on the fire risk assessment, an on-site fire fighting organization shall be developed.

13.2.2 Detailed and documented fire fighting procedures shall be developed for site- and process-specific fire scenarios.

13.2.3 Training of the fire fighting organization shall be based upon specific fire scenarios.

13.2.4 Emergency procedures shall include a documented plan for rapid assembly, transportation of emergency personnel and equipment to the fire scene, and operation of the fire suppression equipment available at the facility.

13.3 Construction. Buildings and structures greater than 465 m^2 (5000 ft^2) shall be of noncombustible construction or protected by an automatic sprinkler system.

13.4 Lightning Protection. Where lightning protection is required, it shall be in accordance with NFPA 780.

13.5 Egress and Exiting.

13.5.1 Two means of egress in accordance with NFPA *101* shall be provided on every floor of all buildings.

13.5.2 Emergency lighting shall be provided at the means of egress stairways in accordance with NFPA *101*, Section 7.9.

13.5.3 Emergency exit signs shall be provided at the means of egress stairways in accordance with NFPA *101*, Section 7.10.

13.6 Yard Hydrant Systems.

13.6.1 The fire risk assessment shall be used to determine requirements for and location of yard hydrants.

13.6.2 Yard hydrants shall be in accordance with NFPA 24.

13.7* Water Supply and Water Distribution Systems.

13.7.1 The fire risk assessment shall be used to determine requirements for water supply and water distribution systems.

13.7.2 Where a fire water supply is required by the risk assessment, capacity and availability shall provide the water demand for fire-fighting purposes, including hose and sprinkler systems, for a minimum duration of 2 hours.

13.7.3* Where fire mains and hydrants are required by the risk assessment, the water supply system shall be installed and maintained in accordance with NFPA 24.

13.7.4 Where public or private fire mains are not provided, alternate water supplies shall comply with NFPA 1142.

13.7.5 Where allowed by the fire risk assessment, process water systems shall be permitted to supply fire mains.

13.8 Flammable and Combustible Liquids.

13.8.1 The storage, use, and handling of flammable and combustible liquids in and around metal mineral processing facilities and on or in equipment in such plants shall conform with NFPA 30.

13.8.2 Material Safety Data Sheets or equivalent listing the flammability characteristics and flash point of flammable and combustible materials shall be kept on site for review by employees and the authority having jurisdiction.

13.9 Compressed Gases. The storage, use, and handling of compressed gases shall be in accordance with NFPA 55 and NFPA 58.

13.10 Rubber and Plastic Lined Equipment.

13.10.1* The fire risk assessment shall be used to determine protection requirements of rubber and plastic lined equipment.

13.10.2 Equipment with internal combustible rubber or plastic linings shall be clearly labeled by placards or stenciling on the side of the lined equipment.

13.10.3 The label shall indicate that a combustible lining is present and shall state "Hot work such as cutting and welding should be avoided."

13.10.4 The label shall be clearly visible.

13.10.5 When hot work must be performed on lined equipment, guidelines in Section 4.4 shall be followed.

13.10.6 Repairs and modifications to rubber or plastic lined equipment using flammable solvents shall require ventilation during solvent use.

13.10.7 Electrical lights and other electrical appliances shall be rated for the hazard when used during repairs and modifications to rubber or plastic lined equipment using flammable solvents.

13.10.8 Equipment and personnel repairing internal liners using flammable solvents shall be grounded against static discharge.

13.10.9 A written pre-planned procedure for emergency response shall be developed for fighting an internal rubber or plastic lined equipment fire.

13.11 Plastic Equipment.

13.11.1* The fire risk assessment shall be used to determine protection requirements of equipment constructed from plastic.

13.11.2 Plastic equipment shall be clearly labeled by placards or stenciling on the side of the equipment.

13.11.3 The label shall indicate that combustible plastic is present and shall state "Hot work such as cutting and welding should be avoided."

13.11.4 The label shall be clearly visible.

13.11.5 When hot work must be performed on plastic equipment, guidelines in Section 4.4 shall be followed.

13.11.6 Repairs and modifications to plastic equipment using flammable solvents shall require ventilation during solvent use.

13.11.7 Electrical lights and other electrical appliances shall be listed for the hazard when used during repairs and modifications to plastic equipment using flammable solvents.

13.11.8 Equipment and personnel repairing plastic equipment using flammable solvents shall be grounded against static discharge.

13.11.9 A written pre-planned procedure for emergency response shall be developed for fighting a plastic equipment fire.

13.12 Belt Conveyors.

13.12.1 Belt alignment limit switches shall be provided on conveyors to shut down belts that are tracking improperly.

13.12.2 Motion-sensing switches shall be provided to detect a slipping or jammed belt and shall be interlocked to shut off driving power when the belt stops or slows down by more than 20 percent of its normal speed.

13.12.3 Sequence switches shall be provided on contributing conveyors to prevent any operating conveyor from discharging material to a stopped downstream conveyor.

13.12.4* Conveyor belt systems shall be inspected and maintained to prevent ignition sources.

13.12.5 Accumulations of rock shall be removed from areas where the rock could jam or contact a rotating part and cause ignition of the belt.

13.12.6* The fire risk assessment shall be used to determine protection requirements of conveyor belts.

13.13 Hydraulic Fluids and Lubricating Oil Systems.

13.13.1* The fire risk assessment shall be used to determine protection requirements of hydraulic fluid and lubrication oil systems.

13.13.2 The use of listed fire-retardant or resistive fluids shall be acceptable as an alternate protection solution for fixed suppression on hydraulic systems.

13.13.3 Hydraulic fluid systems shall be capable of being shut off by one of the following measures:

(1) Actuation of automatic fire suppression or detection systems
(2) Actuation of automatic reservoir low-level, loss-of-pressure, or flow switches
(3) Actuation of manual power shutoff located at least 15.24 m (50 ft) from the hydraulic system or in a separate cutoff area from the hydraulic system

13.13.4 Hydraulic fluid and lubrication oil tanks and pumps, of individual or aggregate quantity in excess of 1892 L (500 gal), shall be located in dedicated cutoff rooms of 1-hour fire resistance.

13.13.5 Individual hydraulic and lubricating oil systems shall be located in a curb or pan capable of containing the entire reservoir capacity.

13.14* Thermal Oil Heating Systems.

13.14.1* Fire protection of thermal oil heating systems shall include as a minimum the following:

(1) A cutoff room of 1-hour fire resistance for thermal oil heater, storage, and expansion tanks and pumps

    Exception: Heat exchangers or other appliances using thermal oil to dry the ore may be located in the general production area.

(2) Interlocks to shut off the thermal oil system upon actuation of a fixed suppression or detection systems
(3) Automatic fixed fire protection system inside the cutoff room

13.14.2 Acceptable fixed fire protection systems described in 13.14.1(3) shall include automatic sprinklers, water spray systems, or foam-water systems.

13.15 Fuel-Fired Equipment. Burner management systems for solid, gas, and liquid fuel delivery systems shall be in accordance with NFPA 85.

13.16* Electrical Equipment Spaces.

13.16.1 The fire risk assessment shall be used to determine fire protection requirements of switch rooms, cable-spreading spaces, cable distribution tunnel and control rooms with electrical switch panels, transformers, and grouped electrical cables.

13.16.2 Electrical equipment shall be installed, tested, inspected, and maintained in accordance with *NFPA 70*.

13.16.3 Control rooms, cable-spreading rooms, transformers, and electrical switch rooms shall be protected with an acceptable fire protection system, including but not limited to cutoffs and barriers, smoke or heat detection, fire-retardant coating, automatic sprinklers, water spray systems, water mist systems, foam water systems, gaseous suppression systems, dry chemical systems, and portable extinguishers.

13.16.4 MCCs shall be protected with an acceptable fire protection system, including but not limited to, 1-hour cutoffs and barriers, smoke or heat detection, fire suppression systems, and portable extinguishers. Acceptable fire suppression systems include automatic sprinklers, water spray systems, water mist systems, foam-water systems, gaseous suppression systems, and dry chemical systems. A fire risk assessment shall be used to determine if fire suppression is not required for MCCs.

13.17 Battery Charging Installations.

13.17.1 Battery charging installations shall have ventilation for the removal of generated gases from charging batteries.

13.17.2 Means shall be provided to flush spilled electrolyte.

13.18* Hydro-Metallurgical Solvent Extraction (SX) Facilities. Section 13.18 shall apply to both new and existing SX facilities.

13.18.1* The fire risk assessment as required in Section 5.1 shall include an evaluation of each of the following:

(1) Use of inherent safety in design of facilities
(2) Methods for reducing or eliminating hazardous fire conditions
(3) Impact of radiant heat, wind effects, and liquid drainage patterns
(4) Use of detection and early fire-warning devices
(5) Use of fixed fire suppression systems
(6) Requirements for on-site fire water availability, quality, and capacity
(7) Normal and emergency means of egress from equipment or workplaces and evacuation to a safe location, such location to be determined by the fire risk assessment
(8) Compartmentalization of equipment, isolation of areas, or provision of barriers or enclosures to prevent or contain the spread of fire
(9) Use of drainage systems to channel spilled solvents during a fire emergency
(10) Availability and accessibility of fire-fighting personnel and fire suppression equipment
(11) Spread of fire to combustible materials in proximity
(12) Any other devices or procedures necessary to protect life and property
(13) Use of combustible plastics in construction and process equipment
(14) Prevention of mist and aerosol generation
(15) Ignition source control
(16) Production and elimination of static electrical sources
(17) Impact of altitude on flash point of the solvents used

13.18.1.1 The fire risk assessment shall not preclude the need for the requirements of Section 13.18.

13.18.2 Yard hydrants shall be installed to cover the entire SX facility.

13.18.2.1 Water duration for yard hydrant systems shall be for 120 minutes.

13.18.2.2 Yard hydrants shall be provided with foam injection capability.

13.18.3 Hot work shall be controlled in SX facilities in accordance with Section 4.4.

13.18.4 Electrical equipment shall be designed in accordance with electrical hazard classification ratings in *NFPA 70*, based on the flammability and process conditions of the solvent.

13.18.5* To prevent static electrical charges, all metallic piping and vessels containing flammable or combustible liquids or vapors shall be bonded and grounded.

13.18.6 Where nonconductive plastic pipes, vessels or flanges are used and cannot be grounded, static charge shall be eliminated by other means.

13.18.7 Enclosed buildings containing flammable or combustible liquids shall be mechanically ventilated in accordance with NFPA 30.

13.18.8* Outdoor mixer-settler cells and other process equipment with covers shall not require mechanical ventilation.

13.18.9* Fire detection with alarm shall be provided where flammable or combustible liquids are present, including but not limited to over solvent tanks, in pipe trenches, over pumps, and inside mixer-settler buildings.

13.18.10* As part of the emergency response, provisions shall be made to shut off valves on pregnant liquor supply (PLS) lines and on organic solvent lines.

13.19* New Solvent Extraction (SX) Facilities. Section 13.19 shall apply to new SX facilities.

13.19.1 Fixed fire suppression shall be provided for the following SX facility areas and equipment:

(1) Buildings housing SX processes
(2) Interior of all mixer-settler vessels/cells
(3) Crud tanks that include treatment filters and centrifuges
(4) Coalescers
(5) Along launders and weirs outside of mixer-settler vessels
(6) Inside pipe trenches carrying solvents
(7) Inside organic solvent and diluent tanks
(8) Inside dikes enclosing organic solvent storage tanks
(9) Over organic solvent pumps
(10) Over elevated pipe racks carrying organic solvents in plastic pipes
(11) Other areas handling, processing, or exposed to flammable or combustible liquids

13.19.1.1* Fire suppression for applications in 13.19.1 shall be water, foam, dry chemical, or water mist.

13.19.1.2* Design of fire suppression systems in 13.19.1 shall be based on criteria set forth in NFPA 11, NFPA 15, NFPA 16, and NFPA 17.

13.19.1.3* Actuation of fire suppression systems in 13.19.1 shall be automatic.

13.19.2 As exposure protection, automatic water-only deluge (open-head) sprinkler systems shall be provided between mixer-settler trains if spaced closer than 15.24 m (50 ft) from each other.

13.19.3 As exposure protection, automatic water-only deluge sprinkler systems shall be provided around the exterior perimeter of organic solvent tanks if spaced closer than 15.24 m (50 ft) from each other.

13.19.4 As exposure protection, automatic fire suppression shall be provided over other critical equipment (i.e., transformers) or outside along important building walls [i.e., motor control center (MCC) rooms] that are within 15.24 m (50 ft) of a solvent fire area.

13.19.5 Hydraulic design of automatic fire suppression systems in 13.19.1 shall include the simultaneous operation of all fire protection systems associated with a single (multi-cell) train.

13.19.6 The total flow rate of foam application and water associated with the discharge of automatic fire extinguishing systems, fixed monitors, and hydrants shall determine the total volume of fire water required.

13.19.7 Solvent spills from the SX facility shall be drained to a safe area, such as a catchment area or pond, via buried or enclosed piping or channels.

13.19.7.1 The drainage system design shall consider both solvent flow as well as water flow from fire suppression systems.

13.19.7.2 Drainage piping or channeling systems shall be arranged to prevent burning solvents from flowing to the safe catchment area or pond.

13.19.7.3 Concrete, steel, or rigid thermoset plastics such as polyvinyl chloride (PVC) or glass fiber reinforced plastic (FRP) shall be permitted for drainage piping or channels.

13.19.7.4 When plastic materials are used for drainage pipes or channels, such pipes or channels shall be buried.

13.19.8 Bulk storage tanks of flammable or combustible solvent shall be located outdoors in a diked area in accordance with the requirements for flammable liquid tanks in NFPA 30.

13.19.9 Solvent extraction process areas shall be provided with minimum 150 mm (6 in.) high curbing to confine and channel solvent spills.

13.19.9.1 Individual curbed areas shall not exceed 465 m^2 (5000 ft^2).

13.19.10 Where trenches or plastic piping containing flammable or combustible organics enter a lower-grade tank farm or pumping area, a barrier wall shall be provided to prevent spilled liquids at the higher level from flowing into the lower area.

13.19.10.1 Where plastic piping containing flammable or combustible liquids passes through a barrier wall, a steel spool pipe of a minimum 1.5 m (5 ft) shall be provided on both sides of the wall.

13.19.10.2 An emergency, remotely actuated shutoff valve shall be provided on pipe lines containing flammable or combustible liquids that penetrate the barrier wall.

13.19.11 Shutoff valves on PLS lines shall be capable of being shut off remotely.

Annex A Explanatory Material

Annex A is not a part of the requirements of this NFPA document but is included for informational purposes only. This annex contains explanatory material, numbered to correspond with the applicable text paragraphs.

A.1.1.1 Because of the uniqueness and often remoteness of metal and nonmetal mines and ore processing facilities, provisions in this standard could differ from commonly accepted fire protection standards and guides devised for other types of occupancies. The provisions of this document are considered necessary to provide a reasonable level of protection from loss of life and property from fire and explosions. They reflect situations and the state of the art at the time the standard was issued.

As of 2001, there were 12,479 metal/nonmetal mining and processing operation in the United States. In the most recent 12-year period, approximately 515 fires of all types were reported.

Fires and explosions in mines and mineral processing plants have caused major loss of property, production equipment, buildings, and business interruption. In the five-year period from 1994 to 1998, mines and quarries of all types averaged $12.3 million a year in direct damage in fires reported to U.S. local fire departments. In the same period, nonmetallic mineral processing and product manufacturing facilities averaged $16.1 million a year in direct damage in fires reported to U.S. local fire departments. *(For more information, see the NFPA Fire Protection Handbook, 2008 edition, Chapter 9, Section 9.16.)*

Fires adversely affect all areas of mining and mineral processing operations, including underground and surface self-propelled and mobile mining equipment, underground fuel storage areas, surface ore concentrating and processing buildings and equipment, and support facilities associated with these activities.

Fire and related hazards in metal ore processing facilities include but are not limited to conveyor belts; rubber lined equipment; combustible and flammable reagents; gaseous, liquid, or solid fuels; mineral extraction solvents and carriers; dielectric, thermal, and lubricating oils; hydraulic fluids; grouped plastic electric cables; and combustible construction. Significant fire and explosions have occurred in concentrator mills due to these hazards.

Ignition sources for these hazards are present and cannot always be controlled. The most common ignition source in this industry is uncontrolled hot work.

Control and awareness of combustible loading, including "hidden" combustibles like rubber or plastic lined equipment, is important to understanding these hazards. Automatic fire suppression systems coupled with effective emergency response have been effective in limiting fire damage in processing facilities.

Most fires involving mobile or self-propelled mining equipment — whether underground or surface— occur on or near engine exhaust systems, high-speed drive lines, malfunctioning high-pressure–high-temperature hydraulic systems, or faulty electrical components. Total elimination of fire hazards on equipment is impossible since sources of ignition and fuel for fires are inherent in the basic equipment design. The fire problem is further complicated by the collection of environmental debris. Therefore, efforts to reduce fire losses on mobile equipment must be aimed at fire prevention and fire suppression.

To improve fire protection and prevention on mining equipment, some manufacturers of mining equipment have placed emphasis on the reduction of the fire potential of specific items in the original design of their equipment. Such items include turbochargers, exhaust manifolds and exhaust pipe shielding and insulation, location of combustible and flammable liquid reservoirs, and hydraulic and fuel line routing.

Most mining equipment is required to have at least one hand-portable extinguisher mounted in a readily accessible location. Extinguishers are most effective where used by trained operators. However, considering the size and configuration of machines found at a mine, fires can be difficult or impossible to fight with a hand-held extinguisher. For this reason, fire suppression systems have been developed to aid in suppressing those fires that are hard to access and thereby to reduce "off-road" equipment fire losses.

The key to operator protection is early detection of fires to provide a warning to the operator, fuel shutoff to minimize fuel for the fire, and fire suppression during its earliest stages. Specialized systems to perform these functions can be required to protect the operator and the machines. To be totally effective, however, system operation must be fully understood by owners and operators, and provisions must be made for periodic inspection and maintenance.

Fire suppression systems, including hand-portable extinguishers, offer the mining industry a cost-effective tool by which personnel and investments in mining equipment can be protected.

It could be necessary for those charged with purchasing, testing, approving, and maintaining fire protection equipment for the mining industry to consult an experienced fire protection specialist.

A.1.1.6 A typical metal mineral processing plant — also called a concentrating or dressing mill — is physically separated from the mining operation, although it can be connected by conveyor systems. Typical metals produced using concentrator plants are gold, silver, platinum, nickel, zinc, lead, molybdenum, and copper. Essentially any metal can be concentrated in this manner. Some concentrating mills are located on floating dredges, such as those used in titanium mining.

The general purpose of the processing plant is to receive crushed ore, further reduce it in size by additional crushing, milling, and screening, and separate waste materials (gangue) from desirable metal mineral values. Most metal mineral mills are similar in that they have large semi-autogenous, ball, or roll mills for fine grinding the ore into a pulp or slurry. Once ground, the slurry is processed by flotation or beneficiation using reagents. After flotation, the concentrate — which can be in the 20 percent to 30 percent metals value range — is filtered or thermally dried and stored. Some metals, like molybdenum, feature combustible thermal oils in the drying process. Concentrate is sent to metallurgical refineries to recover the final pure product. The refinery might be adjacent to the mill but is usually separate.

By-products produced in a typical metal concentrator mill include tailings, which consist of waste gangue and entrained water and process chemicals. This waste is sent to a tailings disposal facility.

A.1.1.7 There are number of processes associated with concentration or refining of metal ores that are not applicable to this standard but deserve mention due to their hazards and integration with the concentration process. These include solvent extraction–electrowinning (SX–EW); pressure leaching processes (using high-pressure autoclave reactors); alumina refineries; metal smelters, including flash furnaces; roasting, sintering, calcining, and electro-refining processes; and gas, liquid, or solid waste handling systems. There are also nonmetal mineral processing plants such as those used for recovering phosphates, nitrates, potash, and soda ash. All of these processes are chemical in nature, and all have serious fire and explosion hazards.

Of particular mention and importance from a potential fire hazard standpoint are solvent extraction (SX) plants, which are covered in Section 13.18 (for new and existing facilities) and Section 13.19 (for new facilities).

An SX plant is a separations process using combustible solvents like kerosene or alcohol for separating valuable metal minerals. An SX process facility often features thousands of gallons of solvent in plastic tanks using plastic piping and can be located outdoors or inside buildings. SX plants are common at copper mines where the oxide content of the ore body allows acid leaching in heaps. They are also common for uranium, nickel, and cobalt.

While kerosene is usually a Class II combustible liquid and in a cold state is relatively difficult to ignite, once ignited it burns similar to other lower flash point hydrocarbons. At high elevations, the flash point can render the material a Class I flammable liquid. In very hot climates, the material can be above its flash point and the potential for heating is increased when the solution is carried in black plastic piping subject to solar heating.

Protection of SX plants needs to consider response time of fire fighters and types of fire fighting appliances and suppression agents. Because of the large quantities of combustible liquids and use of plastic piping and process systems — which can fail prematurely due to fire impingement and rapidly release additional combustible liquids — a well-developed and large area fire could occur in minutes, and responding fire fighters could be faced with protecting exposures rather than suppression of the incipient event. For this reason the use of fast-acting automatic detection and suppression systems is advised. Foam-water systems have proven effective in suppressing combustible liquid fires. If used, consideration needs to be given to providing protection over and under mixer-settlers and tanks, in tunnels with plastic piping, under pipe racks, over pumps, and inside mixer-settlers.

Provision of drainage, confinement, control of static electricity by bonding and grounding, and selection of stout piping systems, such as stainless steel or structural fiberglass reinforced plastic instead of less robust polyethylene, is advised.

A mineral SX plant should not be confused with an agricultural SX plant that uses low flash point flammable solvents, like hexane, for recovering oils from soybeans, canola, and corn, and that has a higher hazard. NFPA 36 applies to protection of agricultural solvent extraction plants but does not apply to protection of mineral solvent extraction plants. There currently are no NFPA standards on mineral SX plants.

A.3.2.1 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

A.3.2.2 Authority Having Jurisdiction (AHJ). The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A.3.2.4 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A.3.3.9 Emergency Egress. See NFPA *101* for the use of the term.

A.3.3.16 Flash Point. The flash point of a liquid having a viscosity less than 45 SUS at 37.8°C (100°F) or a flash point of 93.4°C (200°F) or higher shall be determined in accordance with ASTM D56, *Standard Method of Test for Flash Point by the Tag Closed Cup Tester.*

The flash point of a liquid having a viscosity of 45 SUS or more at 37.8°C (100°F) or a flash point of 93.4°C (200°F) or higher shall be determined in accordance with ASTM D93, *Standard Test Methods for Flash Point by the Pensky-Martens Closed-Cup Tester.*

As an alternative, ASTM D3278, *Standard Method of Tests for Flash Point of Liquids by Small-Scale Closed-Cup Apparatus*, shall be permitted to be used for paints, enamels, lacquers, varnishes, and related products and their components having flash points between 0°C to 110°C (32°F to 230°F), and having a viscosity lower than 150 stokes at 25°C (77°F).

A.3.3.23 Metal Mineral Processing Plant. A mineral processing plant, also called a concentrator mill or a dressing plant, can have crushers; grinding mills; fuel-fired dryers; separation circuits featuring flammable, combustible, or toxic liquid reagents in flotation cells; and possibly special hazard circuits using thermal oils and solvent extraction. A mineral processing plant is usually located close to the mine due to cost of shipping raw ore long distances.

A.3.3.25 Mineral. *Mineral* in this document refers only to metal or nonmetal ores and not to coal.

A.3.3.27 Noncombustible Material. Materials that are reported as passing ASTM E136, *Standard Test Method for Behavior of Materials in a Vertical Tube Furnace at 750°C*, are considered noncombustible materials.

A.3.3.33 Safe Area. Examples are designated welding shops.

A.3.3.37 Self-Igniting Rock. In metal/nonmetal mines this usually pertains to sulfide ores or coal deposits.

A.3.3.39 Solvent Extraction (SX) Facility. A hydrometallurgical solvent extraction facility is not to be confused with an agricultural solvent extraction plant that uses hexane or other low flash point flammable or combustible liquid to recover edible oils such as soy, palm, or corn oil. Agricultural solvent extraction plants are covered by NFPA 36. NFPA 36 is not to be used for protection requirements of hydrometallurgical solvent extraction facilities.

A.4.4.21 For additional information, see NFPA 326 and AWS F4.1, *Safe Practices for the Preparation of Containers and Piping for Welding and Cutting*.

A.5.1 See Annex B for suggested procedure to conduct a fire risk assessment.

A.5.1.4 Examples of where fixed protection might be needed in mineral processing plants include conveyor belts, galleries, tunnels, over rubber and plastic constructed or lined equipment, switch gear rooms, control rooms, change houses, and combustible and flammable liquids storage or process areas. Areas with noncombustible construction or noncombustible contents are areas where fixed protection might not be needed.

A.7.1.1 Some examples of equipment modifications that can favorably reduce risk of fire include physical barrier between fuel and ignition sources, thermal shields over hot surfaces, hydraulic hose and electrical wiring harness rerouting, and power shutoffs.

A.7.1.2 Modifications could affect the life expectancy and certification of diesel-powered equipment and diesel-powered equipment components. It is possible that such a modified machine would not be covered by the manufacturer's warranty or certification. Questions concerning the effect of a proposed modification should be discussed with the diesel-powered equipment manufacturer or the manufacturer's representative.

A.7.4(3) Depending upon the size of the equipment, additional ground-level manual actuators could be needed to provide quick access for manual activation of the system.

A.8.3.4 Where pressurized pipeline systems are used for combustible liquid transfer, consideration should be given to providing a pressure-sensing interlock downstream of the transfer pump discharge. This interlock should be suitable for Class I, Division 2 locations and should be arranged to shut down the pump immediately upon loss of line pressure.

A.9.1 Because of the inherent hazards associated with flammable liquids, the underground storage of flammable liquids should be avoided.

A.9.1.1 Electrical equipment classified as "permissible" is certified as meeting the requirements of 18 CFR, Chapter 1.

A.9.4.2.1 Electrical equipment classified as "permissible" is certified as meeting the requirements of 18 CFR, Chapter 1.

A.10.3 Atmospheric tanks should be built in accordance with good engineering practices.

Information on the design and construction of tanks can be found in API 650, *Standard for Welded Steel Tanks for Oil Storage*; UL 80, *Standard for Steel Tanks for Oil Burner Fuels or Other Combustible Liquids*; or UL 142, *Standard for Steel Aboveground Tanks for Flammable and Combustible Liquids*.

Low-pressure tanks and pressure vessels can be permitted to be used as atmospheric tanks.

A.10.4 Low-pressure tanks should be built in accordance with good engineering practices.

A.10.5 Pressure vessels should be built in accordance with good engineering practices.

Information on the design and construction of pressure vessels can be found in the *Code for Unfired Pressure Vessels*, Section VIII, Division I, of the ASME *Boiler and Pressure Vessel Code*.

A.10.6.2.1 Information on venting can be found in API 2000, *Standard for Venting Atmospheric and Low-Pressure Storage Tanks*.

A.10.9.15 Information on tank foundations can be found in API 620, *Recommended Rules for the Design and Construction of Large, Welded, Low-Pressure Storage Tanks*, Appendix B, and API 650, *Standard for Welded Steel Tanks for Oil Storage*, Appendix E.

A.10.10 No requirements for bonding or grounding to dissipate static electricity are included in this standard for combustible liquids, based upon the fact that NFPA 30 does not require bonding or grounding for combustible liquids handled at temperatures below their flash points.

However, it is recognized that certain conditions can exist that could necessitate bonding or grounding, such as temperature and altitude, which can reduce the flash point of diesel fuel.

For additional information on static electricity, see NFPA 77.

A.11.3.1 Underground shaft mines that use diesel-powered equipment generally employ underground diesel fuel storage areas to facilitate equipment refueling. Adit-type mines in the western United States can initially locate diesel fuel storage and refueling facilities on the surface; however, as the active mine workings progress further from the adit portal(s), these facilities usually are moved underground.

A common means of fire protection currently found in many underground diesel fuel storage areas is a fixed water sprinkler system. The federal Mine Safety and Health Administration (MSHA) currently approves such systems for this application. The consensus of the committee is that this situation represents a significant safety hazard. According to the NFPA *Fire Protection Handbook*, water sprinklers can be used on diesel fuel for control but not for extinguishment.

"The Health and Safety Implications of the Use of Diesel-Powered Equipment in Underground Mines," a report by an interagency task group prepared for MSHA in 1985, concludes that "water spray or fog usually will not extinguish diesel fuel fires."

In an underground mine, fire control is not sufficient; fire extinguishment is essential for the following reasons:

(1) As long as a fire burns, even if it does not grow in intensity or area and appears to be responsive to fire control, toxic smoke and fire gases are produced that can endanger persons in the mine.
(2) According to the NFPA *Fire Protection Handbook*, overpressure failure of containers when exposed to fire is considered the principal hazard of closed-container flammable and combustible liquid storage.
(3) Even a "controlled" fire can cause container failure, producing a fire so intense that the sprinkler system is unable to control it, much less extinguish it.
(4) Water sprays are not effective in extinguishing pressure fires, running fuel fires, and obstructed spill fires, all of which can occur in a diesel refueling area.
(5) Water supplies are limited in many underground mines. Fire control, therefore, should be considered temporary, because the fire will grow immediately to maximum intensity when the water supply is depleted.
(6) The vapor pressure of diesel fuel increases with elevation due to reduced barometric pressure. As a result, even fuels without flash point–reducing additives can become flammable, depending on the altitude at which they are used. This reduction in flash point could result in reclassification of the diesel fuel to a Class IC flammable liquid. There is no clear consensus in the literature and industry practice as to the effectiveness of fixed water sprays in controlling and extinguishing fires involving Class IC flammable liquids. Although industry practice strongly favors fixed water sprays for such applications, the literature and available research results clearly indicate the ineffectiveness of fixed sprays on Class IC liquids, especially on pressure fires, running fuel fires, and obstructed spill fires.

Water sprinkler systems installed for the protection of diesel fuel storage areas might not be effective in suppression even though they do provide good control through cooling; foam-water systems can provide suppression.

For further information on foam-water systems, see NFPA 16.

A.12.2 Fires adversely affect all types of self-propelled and mobile surface mining equipment, including, but not limited to, trucks, front-end loaders, crawlers, drills, shovels, and draglines. Most fires occur on or near engine exhaust systems, high-speed drive lines, malfunctioning high-pressure–high-temperature hydraulic systems, or faulty electrical components.

Total elimination of fire hazards is impossible, because sources of ignition and fuel for fires are inherent in the basic equipment design. The problem is further complicated by the collection of environmental debris. Therefore, efforts to reduce fire losses must be aimed at fire prevention and fire suppression.

To improve fire protection and prevention on surface mining equipment, some manufacturers of mining equipment emphasize the reduction of the fire potential of specific items in the original design of their equipment. Such items include turbochargers, exhaust manifolds and exhaust pipe shielding and insulation, location of combustible and flammable liquid reservoirs, and hydraulic and fuel-line routing.

Most surface mining equipment is required to have at least one hand-portable extinguisher mounted in a readily accessible location. Extinguishers are most effective when used by trained operators. However, considering the size and configuration of machines found at a mine, fires can be difficult or impossible to fight with a hand-held extinguisher. For this reason, fire suppression systems have been developed to aid in suppressing those fires that are hard to access and thereby to reduce "off-road" equipment fire losses.

The key to operator protection is early detection of fires to provide a warning to the operator, fuel shutoff to minimize fuel for the fire, and fire suppression during its earliest stages. Specialized systems to perform these functions can be required to protect the operator and the machines. To be totally effective, however, system operation must be fully understood by owners and operators, and provisions must be made for periodic inspection and maintenance.

Fire suppression systems, including hand-portable extinguishers, offer the mining industry a cost-effective tool by which personnel and investments in mining equipment can be protected.

A.12.3.4.1 Depending on the size of the vehicle and size of the fire, a 9.1 kg (20 lb) fire extinguisher could be more effective.

A.12.3.4.9(8) The same record tag or label can also indicate if recharging was performed.

A.12.3.5.2.1 A dry-chemical system is the preferred system for these areas.

A.12.3.5.2.2 Smoke detectors are not recommended because of the harsh environment.

A.12.3.5.3.1 Automatic systems are not necessary if the area is easily accessible for manual fire fighting.

A.12.3.5.4.2 Carbon dioxide would not be the best choice for fighting this type of fire due to the potential for the gas to be dispersed before the oxygen concentration is reduced enough to affect the fire.

For transformers over 5000 kVA, a fixed fire suppression system is recommended.

A.12.3.6.1.1 Equipment in this category is generally a vehicle weight of 90,720 kg (200,000 lb) or more and the size of a Hitachi 1800, Caterpillar 5230, Komatsu PC1000-6, Liebherr R984, DeMag H95, and Hitachi 1100.

A.12.3.8.1.1 Depending on the size of the vehicle and size of the fire, a 9.1 kg (20 lb) fire extinguisher could be more effective.

A.12.3.8.2.5 NFPA and manufacturers require 6-month inspections.

A.12.3.8.3.2 The following are examples of large equipment:

(1) Track dozer of 300 horsepower or more or 31,750 kg (70,000 lb) weight or more (e.g., Caterpillar D8R)
(2) Front-end loader of 400 horsepower or more and vehicle weight of 45,400 kg (100,000 lb) (e.g., Caterpillar 988)
(3) Wheel bulldozer of 300 horsepower or more and vehicle weight of 27,200 kg (60,000 lb) or more (e.g., Caterpillar 824G)
(4) Grader of 275 horsepower or more and vehicle weight of 25,000 kg (55,000 lb) or more (e.g., Caterpillar 16H)
(5) Pull-type scraper of 450 horsepower or more and vehicle weight of 44,450 kg (98,000 lb) or more (Caterpillar 631E)
(6) Scraper with push/pull twin engine of 450 horsepower and 490 horsepower or more and vehicle weight of 51,260 kg (113,000 lb) or more (e.g., Caterpillar 637E)
(7) Blast hole drill of 360 horsepower or more and weight of 30,845 kg (68,000 lb) or more (e.g., Ingersol-Rand DM-30)

A.12.3.8.3.3(4) Depending on the size of the equipment, additional ground-level manual actuators could be needed to provide quick access for manual activation of the system.

A.12.3.8.3.7 Periodic maintenance is required by NFPA standards and by manufacturers. Although other training resources are available, the fire suppression system manufacturer is the best source for proper training regarding their equipment.

A.13.7 A readily available supply can include a dedicated fire protection water supply, a pond or other large body of water, an industrial process water system, or large water trucks (tankers). If water trucks (tankers) are used, they should be of a capacity and quantity to deliver a continuous source of water for the duration of the fire-fighting effort. Personnel should be trained in emergency vehicle operation and mobile water supply shuttle procedures. If an impounded body of water is provided, it should be close and accessible enough to the protected property to allow fire fighters a quick response.

A.13.7.3 Chapter 5 and Appendix G of NFPA 1142 outline suggested methods for determining the estimated water supply (fire flow) that can be necessary for fire-fighting purposes.

A.13.10.1 The following should be considered when conducting a fire risk assessment on rubber and plastic lined equipment:

(1) Many fires occur annually inside rubber lined equipment in concentrator plants.
(2) Many rubber lined equipment fires are quickly controlled and not reported, but some have spread throughout a circuit or several circuits and have caused significant property damage and business interruption. If located near a wall or ceiling, heat inside an internal rubber lined system might cause structural damage.
(3) Rubber lined equipment fires are usually caused by hot work. These fires can occur when heating the outside of a steel pipe lined with rubber or plastic, with heat passing into the interior lining and ignition inside. They could also occur due to hot work over open-topped tanks and vessels, which will normally occur when the plant is down for maintenance and the systems are dry.
(4) Once a fire enters the inside of a dry rubber lined system, it can spread unchecked.
(5) Where practical during new process installations or modifications, the use of rubber or plastic lining and plastic vessel and piping should be minimized or eliminated.
(6) Hot work on or over plastic or rubber lined vessels should be minimized, and alternate methods of repair exhausted prior to permitting hot work.
(7) When hot work is necessary, and where practical, vessels can be flooded with process or fire protection water to minimize internal ignition.
(8) When hot work is necessary, and where practical, vessels and piping should be isolated by closing process valves or breaking connection to minimize internal fire spread between processing circuits.
(9) Protection options might include smoke or heat detection, local fixed automatic sprinkler or water spray suppression, extinguishers, or hand hose lines. Flooding a circuit with process water is a good suppression technique as long as the responding emergency team knows which valves to open and has planned for this contingency.

A.13.11.1 The following should be considered when conducting a fire risk assessment on plastic constructed equipment:

(1) Similar to rubber or plastic lined equipment, there is increasingly new equipment constructed entirely of plastic, such as process vessels, pipes, and cooling towers.
(2) Hazards are similar to rubber lined equipment, and identification, labeling, hazard awareness, and fire planning are required.
(3) The use of fixed automatic sprinkler systems over large concentrations of plastic equipment has been effective.

A.13.12.4 The following should be considered when conducting a fire risk assessment on a conveyor system:

(1) Belt fire retardancy
(2) Size and speed
(3) Degree of confinement
(4) Accessibility for manual fire fighting

Automatic sprinklers have been effective in limiting damage in conveyor systems.

A.13.12.6 Conveyor belt ignition sources include friction points, hot bearings, tracking, frame damage, electrical, combustible storage, hot work, and spontaneous combustion of spilled fuels. Acceptable protection systems for conveyors shall include automatic sprinklers, water spray systems, foam water systems, smoke and heat detection systems, dry chemical systems, pre-engineered dry chemical or wet chemical systems, portable extinguishers, and hand hose lines.

A.13.13.1 The following should be considered when conducting a fire risk assessment on a hydraulic or lubricating oil system:

(1) Individual and aggregate quantity of fluid or oil
(2) System location
(3) System design
(4) Type and fire hazard of fluid or oil
(5) Pressures
(6) Temperatures
(7) Presence of ignition sources
(8) Importance
(9) Attended or not
(10) Presence of personnel in area

Hydraulic fluid and lubrication oil tanks and pumps should be located as to not expose grouped electrical cables, rubber or plastic equipment, or other critical equipment to fire damage.

Acceptable protection systems shall include automatic sprinklers, water spray systems, dry chemical systems, pre-engineered dry chemical or wet chemical systems, portable hand hose lines and extinguishers, and detection.

A.13.14 Thermal oil systems are used in some mineral processing plants, such as molybdenum concentrator mills, for drying ore.

Chapter 8 of NFPA 664 is the primary reference in NFPA standards for thermal oil systems used in industrial processes. Even though the woodworking industry has unique equipment, the hot oil heating and distribution systems are similar, and the concepts provided in this standard can be utilized for the mineral processing industry.

A.13.14.1 As determined by the fire risk assessment, additional fire protection might be needed to fully protect thermal oil systems.

The following should be considered when conducting a fire risk assessment on a thermal oil system:

(1) Additional or back-up fixed fire suppression
(2) Locating the heater and tanks outdoors or in detached buildings
(3) Proper location and confinement of expansion and storage tanks and heaters
(4) Proper piping arrangement
(5) Process interlocks and controls
(6) Explosion protection
(7) Damage limiting construction from an oil mist explosion

A.13.16 Positive pressure should be maintained in electrical equipment rooms such as switch gear, motor control centers, and cable-spreading rooms to prevent the entry of fugitive dust that can cause overheating or short circuits.

Thermographic scanning can be performed on transformers, switchgear, and motor starters on an annual basis.

A.13.18 See Table A.13.18 for fire experience data justifying the addition of the requirements in Section 13.18.

A.13.18.1 The design intent within this standard for protection of hydro-metallurgical solvent extraction (SX) facilities is to limit a fire to a single train rather than to a single cell. A typical SX facility will have multiple (three or more) mixer-settler cells comprising a single train. The distance between cells within a single train might be only a few meters (feet), usually the width of a walkway. Parallel trains of multiple cells might also be present and these are usually separated from adjacent trains by 7.6 m to 15.24 m (25 ft to 50 ft), usually the width of a roadway.

Should the design intent be to limit the fire to a single cell, then additional fire protection might be required. The risk assessment should define the level of tolerable risk. The actions taken might then focus more on spatial separation, barriers, construction, and so forth.

Mining companies use solvent extraction (SX) processes to separate valuable base metal minerals. This technology is common with copper, uranium, nickel, cobalt, and many specialty metals. A typical hydro-metallurgical SX facility features thousands if not hundreds of thousands of cubic meters (gallons) of flammable or combustible liquids and is commonly located at a remote mining site near the ore body being mined. Larger SX facilities — notably copper and uranium — are located outdoors but might be located indoors for nickel, cobalt, lithium, iodine, and other metals.

A hydro-metallurgical SX facility should not be confused with an agricultural SX facility that uses low flash point flammable solvents, like hexane, for recovering edible oils from soybeans, canola, and corn, and that has a higher hazard. NFPA 36 applies to protection of agricultural solvent extraction plants but does not apply to and should not be applied for protection of hydro-metallurgical SX facilities.

Severe fire hazards exist with mineral SX facilities due to large volumes of combustible or flammable liquids, often in large open pools. Because SX solvents are normally cold (that is, at ambient temperature well below their boiling points), severe explosion hazards generally do not exist. Most large copper-uranium–type SX facilities use a grade of high purity kerosene, but some more refined metals like lithium feature lower flash point alcohols. Fires are generally two-dimensional pool fires rather than three-dimensional fires. Rarely will a pressurized jet spray occur. SX operations at elevated temperatures also affect the flash point of the solvent (refer to A.13.18.5).

Historically, losses in hydro-metallurgical SX facilities have been infrequent but severe. Two significantly large SX fires occurred within 6 months at one Australian copper-uranium mine. The primary conclusions from the two Australian fires are the following:

(1) Thermoplastic high density polyethylene (HDPE) pipes fail prematurely under fire conditions and rapidly release solvents.
(2) Plastic pipes can allow fire spread internally within the pipes.
(3) Stainless steel piping is preferable to plastic but can be attacked by chlorides and might not be suitable for all SX facility services.
(4) While combustible, structural fiber reinforced plastic (FRP) piping is better than HDPE because it does not soften or fail as fast.
(5) Electrical static charge buildup can occur in both metal and plastic due to the movement of flammable or combustible solvents.
(6) Static charge can potentially ignite solvent mists inside pipes.
(7) Static charge can be minimized by:
    (a) Conductive lining inside pipes
    (b) Improved grounding and bonding
    (c) Control of free-falling liquids and mist generation by submerging pipes in the solution
(8) High speed fire detection systems are preferable.
(9) Fireproofing of control system cabling is needed.
(10) Larger capacity fire protection/suppression systems are needed as follows:
    (a) Foam-water suppression systems are preferable to water-based systems.
    (b) High capacity fire water pumping systems.
    (c) Foam-water systems on pipe racks.
    (d) Foam-water systems for all diked areas.
    (e) Deluge (open-head) protection on solvent feed pumps.
(11) High capacity drainage systems are needed.
(12) Diversion systems for spilled solvents might be needed.
(13) Improved dike design is needed to minimize solvent pooling.
(14) Separation of equipment and financial assets.

Table A.13.18 Example Global Fire Losses Involving Hydro-Metallurgical Solvent Extraction Plants[1]

Location	Date	Process	Protection	Incident	Cause	Results
Norway (Ref: 2)	1972	Cobalt-nickel SX using kerosene; glass piping; indoor process	Manual response with water hoses	Solvent spill into pit below M-S; glass piping failed under fire exposure	Hot work	Three fatalities; plant destroyed; $75 M damage; six months production outage
U.S. (Ref: Private files)	1975	Rhenium-tungsten SX using mineral spirits and perchloric acid; plastic piping (FRP); indoor process	Automatic sprinklers over process area; manual response with water hoses	Small solvent spill spread into M-S cells and through plant; additional solvent fed by failed plastic pipes	Perchloric acid reaction	Plant destroyed; >$10 M damage; six months production outage
Namibia (Ref: Private files)	1978	Uranium SX using kerosene; outdoor process; plastic piping	Manual response with water hoses	Solvent leaked from plastic pipe; additional solvent fed by failed plastic pipes	Electrical	Total plant damage; >$50 M damage; four months production outage
Australia (Ref: 3, 4)	1999	Uranium-copper SX using kerosene; outdoor process; plastic (HDPE) piping	Partial foam-water sprinklers; manual response with foam-monitor nozzles	Solvent release at plastic pipe; fire spread throughout local area; additional solvent fed by failed plastic pipes	Not reported	Partial plant damage; >$40 M damage; nine months production outage
Australia (Ref: 3, 4)	2001	Uranium-copper SX using kerosene; outdoor process; plastic (HDPE) piping	Partial foam-water sprinklers; manual response with foam-monitor nozzles	Solvent release at plastic pipe; fire spread throughout wide area; additional solvent fed by failed plastic pipes	Possible static ignition inside nonconductive plastic pipe	Widespread plant severe damage; >$100 M damage; two years production outage
U.S. (Ref: 4, 5)	2003	Copper SX using kerosene solvent; outdoor process	Unknown	Solvent fire involving M-S cells	Unknown	Four M-S cells partially damaged; $5–10 M damage reported by AP
Mexico (Ref: Internet news services)	2003	Copper SX using kerosene solvent; outdoor process	Unknown	Solvent fire involving M-S cells	Not reported	Not reported

Note: Financial loss estimates are indexed to 2005 U.S. currency.

The fires demonstrated that more rigorous and comprehensive fire protection standards are needed for SX facilities. They also demonstrated the need for process safety management (PSM) oversight and the need for better inherent safety practices in SX facility design.

The need for fixed automatic fire suppression systems actuated by high speed detection systems is readily apparent. A number of suppression systems such as closed head or deluge water-spray, foam-water delivered by nozzles or foam chambers, dry chemical, or high pressure water mist might be applicable and suitable, depending on local conditions. Drainage, isolation, and confinement are also important protection measures.

Some protection solutions and options are as follows:

(1) Where possible, avoid below-grade spaces for tank farms and process equipment. Where possible, site all facilities at the same grade.
(2) Where lower grade tank farms are present and where solvents can flow from upper level processes, provide a barrier to flow. Where plastic pipes penetrate a barrier, the use of steel spools on both sides of the barrier should be considered. The steel spool pieces can help prevent internal fire spread within the plastic pipes. A 3 m (10 ft) long steel spool has proven effective.
(3) Where pipes enter a lower grade tank farm, provide automatic shutoff valves to prevent continued flow of organic solvents or drainage into a fire area.
(4) Avoid use of sub-grade trenches for solvent piping systems. Where possible, locate pipes above grade. Where trenches are required, subdivide trenches with dikes or curbs and do not drain into lower grade areas such as tank farms.
(5) Provide dikes and curbs around tanks, pumps, and process vessels.
(6) Avoid or minimize the use of combustible (plastic) and frangible (glass) piping systems and vessels. Avoid the use of thermoplastics such as HDPE, medium density polyethylene (MDPE), and polypropylene (PP) for piping systems.
(7) Avoid the use of rubber couplings on solvent lines, especially on pump suction lines.
(8) Substitute steel or concrete for plastic where possible for vessels and piping.
(9) Where use of steel piping is not possible due to corrosive effects, substitute a structural (thermoset) plastic such as fiber reinforced plastic (FRP) or polyvinyl chloride (PVC).
(10) Consider drainage patterns during design. Where practical, provide emergency drainage to a remote catch basin or pond from all diked areas and pipe trenches.
(11) Provide emergency dump capability from all tanks and vessels that actuates either manually or upon fire detection with drainage to remote catch basin or pond.
(12) Space mixer-settler tanks and storage tanks as far apart as possible.
(13) Lower roofs and covers on tanks and process vessel to minimize vapor collection space above liquid surfaces.
(14) Consider ignition sources in design.
    (a) Where nonconductive* solvents are used with plastic piping systems, provide a conductive internal pipe liner (i.e., carbon) to dissipate static charges generated by liquid flow. Bond and ground the system, including at flanges. [*Note: A conductive fluid is one with a conductivity of 250 picosiemens per meter (pS/m) or greater.]
    (b) Submerge or lower solvent feed pipes where they enter solvent pools (i.e., inside mixer-settler and tank discharge) to minimize static discharge from free-falling flammable liquids and to minimize solvent mist development.
    (c) Inspect piping for jarosite or other nonconductive inorganic coating that might compromise conductive liners.
    (d) Provide electrically classified electrical equipment in solvent handling areas. Base the classification on types and hazards of solvents in process. In some cases, explosionproof equipment may be needed.
(15) Provide fixed water, foam-water, or dry chemical fire suppression as follows:
    (a) Interior of mixer-settler vessels
    (b) Over the surface of open mixer-settler tanks
    (c) Along launders and open solvent weirs outside of mixer-settler vessels
    (d) Inside sub-grade pipe trenches carrying solvents where drainage is missing or poor, and liquids can accumulate
    (e) Inside solvent storage tanks
    (f) Inside dikes enclosing solvent storage tanks
    (g) Over solvent pumps
    (h) Along the exterior sides of tanks and mixer-settlers if spaced closer than 15 m (50 ft) from each other
    (i) Over elevated pipe racks carrying flammable solvents in plastic pipes
    (j) Over other critical equipment (like transformers) or outside along important building walls (i.e., MCC rooms) that are within 15 m (50 ft) of a solvent fire area
(16) Conduct a process hazard analysis (such as a HAZOP) on all new and existing SX facilities. Conduct revalidation process hazard analysis (PHA) every 5 years and during major changes.
(17) Operate facility under a process safety management system with emphasis on management of change.

The use of inherent safety (IS) principles in design and operation of solvent extraction (SX) facilities is advised.

The mining industry has designed and constructed facilities with an emphasis on personnel safety, production efficiency, and cost effectiveness. The use of IS to eliminate or minimize property fire exposures in the mining industry has not seen widespread practice. Lessons learned from the mainstream chemical processing industries (CPI) appear not to have been well-communicated or applied.

As an example, most copper SX facilities in use today have been designed to use some form of a sub-grade processing area (tank farm) and one-way gravity flow as a cost- and production-effective solution for transferring liquids and minerals through the process. This has resulted in SX facilities constructed with process equipment at different grade levels so that solutions can flow “downhill” and accumulate. Because of the use of large quantities of combustible or flammable liquids and the potential for these liquids — if released — to flow unimpeded into other areas, gravity SX processes represent severe inherent fire consequences unless costly barriers, drainage, and channeling are also provided.

While this layout is used to ensure a cost-effective operation, it has resulted in significant exposures to high value production and equipment. The use of sub-grade production units is a generally inherent unsafe layout where flammable liquids are used.

Gravity-assist layout is only one example where copper SX facilities have been designed and constructed without IS consideration. The use of combustible and frangible corrosion-resistant materials — such as glass, wood, and plastic — for flammable/combustible liquid storage, processing, and piping systems has significantly increased the fire hazards of these facilities. These construction materials are not of sufficient strength and durability to prevent fire spread and can rapidly fail under fire conditions, releasing flammable contents.

Another example of inherently unsafe layout is the widespread use of sub-grade trenches to carry solvent pipe systems. Access to trenches for fire fighting is usually limited and the trenches often drain directly into the lower grade tank farm areas. Trenches usually encircle solvent-filled cells and have open grated coverings; therefore they represent severe fire risk to production equipment such as mixer-settlers (M-S). Trenches also offer low spots for vapors or liquids to accumulate and might require mechanical ventilation systems to prevent flammable vapor accumulation. The use of plastic piping in trenches further increases the hazard. The CPI long ago discontinued the use of sub-grade trenches for transporting combustible/flammable materials, replaced with elevated, easily accessible, and well-ventilated pipe racks.

The classical and common approach to loss prevention for industrial facilities has been to accept a hazard and to protect against it. This approach usually requires expensive and sophisticated retrofitted protection systems, which are subject to failure during the life of the plant. An inherently safer plant eliminates or reduces the hazard to where protection systems might not be needed or can be reduced, saving initial installation cost, lifetime maintenance and testing, and potential loss costs should systems fail.

The "hypothetical" ideal IS approach would be to completely change the technology or process chemistry of SX facilities. The extent to which this could be technically or economically achieved is not known, but some ideas are the following:

(1) Develop and use a nonflammable organic solvent.
(2) Develop and use a less flammable organic solvent.
(3) Find an additive that lowers the resistance coefficient of the solvent to eliminate the potential for static electricity generation.
(4) Develop a new process to extract minerals by significant reduction in quantities and flow of solvent and eliminate large open pools of flammable liquids.

Given that the basic science and technology of a well-established process cannot always be economically changed and that combustible solvents will likely continue to be used in large quantities, potential IS opportunities should focus on changes to design and layout concepts. Some ideas are the following:

(1) Stop or reduce the practice of gravity flow in the SX process.
(2) Install equipment and processes at the same grade level rather than using lower grade tank farms.
(3) Eliminate the use of sub-grade trenches for piping; place piping on elevated pipe racks located away from solvent storage or drainage discharge areas.
(4) Separate buildings, vessels, and process areas based on a risk assessment that includes the impact of radiant heat, wind effects, and drainage patterns.
(5) Lower mixer-settler roofs to rest on or near the top of the liquid layer to minimize or eliminate space for flammable vapor accumulation.
(6) Provide liquid barriers such as walls, curbs, and dikes between buildings, vessels, and process areas.
(7) Provide high-capacity drainage systems for spilled solvents, with discharge to a safe, remote area.
(8) Provide high-capacity emergency dump systems for mixer-settler cells and other vessels that contain large quantities of solvents, with discharge to a safe, remote area.
(9) Locate solvent pumps outside of dikes or sub-grade areas that enclose solvent tanks and other equipment.
(10) Separate process control and safety interlock instrumentation from power cables.
(11) Use robust, fire-resistant, conductive materials (like stainless steel) for piping and vessels rather than combustible, frangible, or nonconductive materials like thermoplastics or glass. When steel cannot be used, consider use of a more durable and fire-resistant structural thermoset plastic such as FRP/GRP with a conductive lining.
(12) Eliminate polymeric materials such as rubber for flexible connections on piping and pumps.
(13) Use seal-less or double sealed pumps for solvents.
(14) Use cooling water jackets around pump seals and bearings.
(15) Find methods to reduce static or mist/aerosol generation in solvent systems such as submerging in-feed nozzles, minimizing bends and restrictions in piping, reducing solvent flow velocities, and using low-turbulence pumps.
(16) Provide high capacity emergency dump systems for mixer-settler cells and other vessels containing large quantities of solvents, with discharge to a safe, remote area.

A.13.18.5 Because some SX facilities are located at high altitudes, flash point assignment can be critical to the risk assessment. Flash points, when tested, are calibrated and reported based on mean sea level in accordance with ASTM D56, *Standard Test Method for Flash Point by the Tag Closed Cup Tester.* Due to partial pressure effects, flash points decrease as altitude increases. For example, a combustible liquid with a flash point of 41°C (105°F) at sea level has a flash point of 33°C (91°F) at 3,048 m (10,000 ft) and 30°C (86°F) at 4,268 m (14,000 ft).

A.13.18.8 Because mineral solvents are usually organic, they are heavier than air, and suction for ventilation systems, when provided, should be near floor level.

A.13.18.9 Suppressing a fire in flammable solvents depends to a great extent on speed of detection. UV/IR detection systems have proven suitable for enclosed mixer-settler cells. Electrical resistance wires have proven effective in pipe trenches and along pipe racks. Other more conventional heat and flame detection systems are also suitable if properly located, spaced, and calibrated.

A.13.18.10 Pregnant liquor solution (PLS) feed is a noncombustible acidic feedstock solution feeding the facility. This is usually gravity-fed from a PLS holding pond above the SX facility. Should a fire occur and PLS solution be allowed to continue to flow into the SX facility, mixer-settler cells might overflow and spread burning and/or high-acid concentration solvents throughout the facility. It is necessary to have control over this feed system in an emergency from both a fire perspective and an environmental perspective. Either manual or automatic valves are suitable. When manual valves are used, the emergency response plan should include provisions to shut off the PLS valve.

A.13.19 See Table A.13.18 for fire experience data justifying the addition of the requirements in Section 13.19.

A.13.19.1.1 Although water-only deluge, foam-water, and dry chemical systems might be effective in controlling or suppressing SX facility fires, there might be use for more than one application in a given facility. Manual response has been ineffective in recent losses, and automatic suppression is advised for both existing and new facilities.

While water spray can be effective, due to potentially high flow requirements a mixer-settler cell might overflow during the suppression process. This might create additional concerns with drainage and fire spread.

Foam has been shown to be an effective suppressant medium for SX fires. However, environmental aspects, potential contamination of process liquids (particularly associated with accidental system initiation), and the difficulty or inability to conduct system flow tests on a periodic basis are negative points in the selection of foam.

High pressure water mist or fog might prove to be a potentially effective suppressant medium and might not create the contamination, environmental, and testing obstacles that accompany foam or the large volumes that accompany conventional high density water deluge systems. Currently, there are no public domain tests conducted on mist systems for pool fires of the size involved in a large SX settler; thus, actual suppressability under all fire conditions has not been demonstrated.

A.13.19.1.2 The following best practices design guidance for automatic fire suppression systems is advised:

For settler tanks or cells, use either Type 1 foam chambers or open head deluge sprinklers with foam discharge. When using foam chambers, provide a 3 percent aqueous film-forming foam (AFFF) foam discharge, in accordance with NFPA 11, with a density of 4.1 L/min/m^2 (0.10 gpm/ft^2) over the entire settler area. When using open head deluge sprinklers, provide a 3 percent AFFF foam discharge, in accordance with NFPA 16, with a density of 6.5 L/min/m^2 (0.16 gpm/ft^2). Design for a 20-minute discharge period.

For mixers, launders, drainage sumps, and piping trenches, use open head deluge sprinklers and provide a 3 percent AFFF foam discharge, in accordance with NFPA 16, with a density of 6.5 L/min/m^2 (0.16 gpm/ft^2) and a 20-minute foam discharge period.

For the interior of tank farm vessels containing combustible or flammable liquids such as loaded organic tanks, coalescers, crud treatment tanks, and diluent tanks use a Type 1 foam chamber and provide a 3 percent automatic AFFF foam discharge, in accordance with NFPA 11, into each of the tanks with a density of 4.1 L/min/m^2 (0.10 gpm/ft^2) and a 20- minute foam discharge period.

For the exterior surfaces of tank farm equipment containing combustible or flammable liquids such as loaded organic tanks, coalescers, crud treatment tanks, diluent tanks, crud treatment filters, centrifuges, pumps, and pipe racks, provide automatic open head (water only) deluge sprinklers based on a discharge density of 10.2 L/min/m^2 (0.25 gpm/ft^2).

A.13.19.1.3 Actuation of automatic fire suppression systems can be done using ultraviolet/infrared (UV/IR) dual spectrum detectors, heat detection cable, rate of rise heat detectors, or standard air pilot heads. High speed detection is considered advisable to suppress a solvent fire in its incipient stages.

Annex B Fire Risk Assessment

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

B.1 Fire Risk Assessment. There are many techniques available to assess risk. The four general techniques are experience, augmented experience, creative, and analytical.

Experience (qualitative) techniques are as follows:

(1) Use of standard designs
(2) Use of recognized standards
(3) Use of experts
(4) Qualitative approach

Augmented experience (qualitative) techniques are as follows:

(1) Secondary safety checks outside of design process
(2) Safety review meetings
(3) Multidisciplinary teams
(4) Avoid blind spots
(5) "What-if" analysis
(6) Qualitative approach

Creative (qualitative) techniques are as follows:

(1) Seek improvements or innovations
(2) Brainstorming
(3) Hazard and operability studies

Analytical (quantitative) techniques are as follows:

(1) Logic trees
(2) Fault event trees
(3) Failure modes and analysis
(4) Quantitative risk assessment
(5) Detailed analytical checklists

In all cases, a fire risk assessment consists of the following four steps:

(1) Identify the potential for fire and explosion.
(2) Assess the consequences of fire and explosion.
(3) Determine the need for fire protection.
(4) Select appropriate option(s).

The following fire risk assessment outline is a suggested procedure to identify the elements in the items defined above. Figure B.1 provides a diagram of the process. Specific examples are given for risks associated with mobile and self-propelled equipment, but the process can be used for other hazards such as conveyor belts, rubber lined equipment, and building protection.

Additional guidance in performing fire risk assessments is provided in several of the reference publications listed in Annex C.

B.1.1 Identify the Potential for Fire and Explosion.

B.1.1.1 Ignition sources are as follows:

(1) High temperatures, which are usually found in the vicinity of a vehicle engine and exhaust system; pumps; batteries; wiring; switches; electrical motors; generators; and friction sources such as bearings, brakes, and gears
(2) Electrical, including switch gear; MCC; circuit breakers; motors and generators; transformers; battery boxes; substations; cable reels, trays, and splices; and collector rings
(3) Hot work such as cutting and welding
(4) Other, including smoking materials, chemical reactions, and spontaneous ignition sources

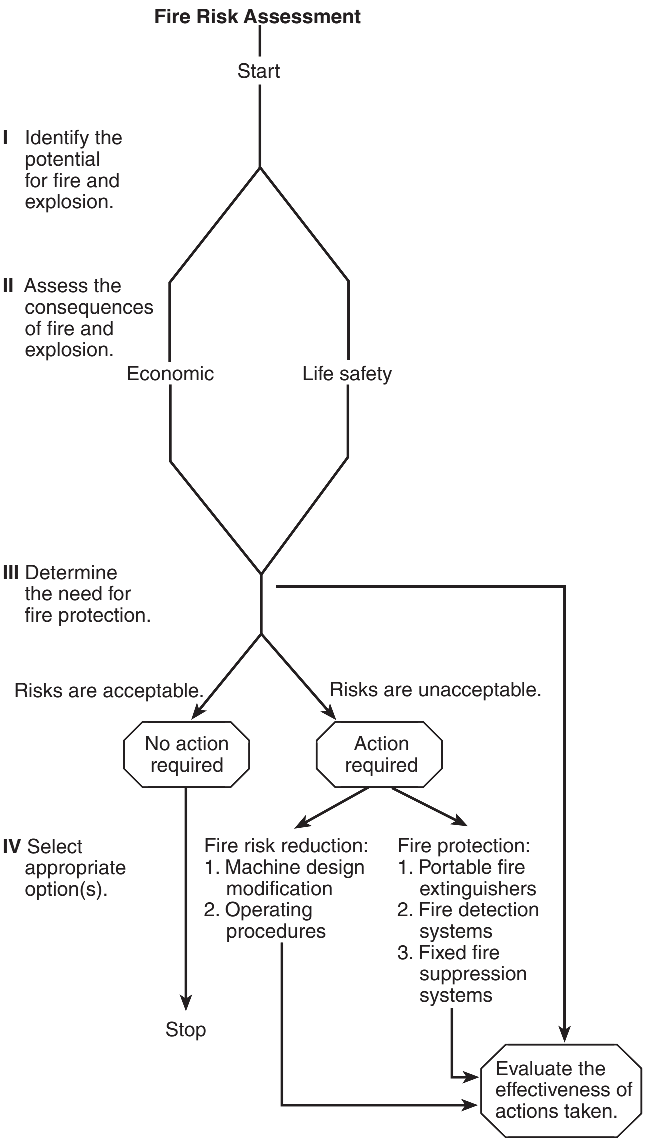

FIGURE B.1 Fire Risk Assessment Chart.

B.1.1.2 Fuel sources are as follows:

(1) Class A, including combustible debris, wood, rags, electrical insulation, coal dust, upholstery, hoses, tires, and seats
(2) Class B, including flammable and combustible liquid materials such as gasoline, diesel fuel, liquefied petroleum gas (propane), hydraulic fluids, some coolant combinations, grease, and oil
(3) Class D, which includes some new mobile equipment that have magnesium transmission components that cannot be extinguished with conventional fire suppression agents

B.1.1.3 Probability of the coexistence of fuel and ignition sources is as follows:

(1) Proximity of fuel to ignition sources should be assessed as follows:
    (a) An assessment should be made of existing areas where lubrication, hydraulic oil, fuel lines, rubber and plastic, and other combustibles are in proximity to an ignition source.
    (b) In identifying risk areas, note that a combustible liquid can spray or drip onto a hot surface remote from the rupture or leak point.
(2) Previous fire experience on mobile equipment and in industrial settings similar to mining should be considered in the fire risk assessment.
(3) Quality of maintenance should be assessed as follows:
    (a) Replacement parts should be at least equal in performance to original parts. Examples are hoses, bearings, fittings, and electrical equipment on mobile equipment or bearings on motors for conveyor systems.
    (b) Maintenance should be performed in accordance with recommendations and schedules supplied by the equipment manufacturer.
(4) The presence of accumulations of combustible materials such as oil-soaked waste and fuel spillage represent potential fire hazards.

B.1.2 Assess the Consequences of Fire and Explosion.

B.1.2.1 Personnel exposure should be assessed as follows:

(1) Determine the number of persons involved and their location during routine and maintenance operations.
(2) Determine the exposure to potential fire and explosion risks for each person and whether the fire and smoke could impair safe egress from his or her work location.

B.1.2.2 Economic risks should be assessed as follows:

(1) Consider the cost of repairs, replacement, cleanup, and damage to the work site.
(2) Items to consider are production loss, personnel overtime, interruption of customer deliveries, and replacement equipment rental.

B.1.3 Determine the Need for Fire Protection.

B.1.3.1 Mandatory Requirements. Certain fire prevention and fire suppression requirements are mandated by company policy, insurance companies, and government agencies.

B.1.3.2 Identified Needs. Additional fire precautions beyond those that are mandated might prove to be necessary, after the fire risk assessment.

B.1.3.3 Evaluation. If the fire risk assessment has disclosed unacceptable personnel risks, economic risks, or both, appropriate fire protection options should be determined. If the risks are found acceptable, no further action is required.

B.1.4 Select Appropriate Option(s).

B.1.4.1 Risk reduction should be considered as follows:

(1) Evaluate equipment to determine whether the risk from the start or the spread of a fire or the risk to personnel from a fire can be reduced. Examples concerning how to reduce the start or spread of a fire include physical barriers between fuel sources and ignition sources; thermal shields over hot surfaces; hose and wiring harness routing, support, and protection; and power shutoffs. Examples for reducing the threat of fire to personnel include emergency egress provisions and relocating or shielding potential fire hazards.
(2) Reduce the threat of fire and explosion through implementation of policies and procedures. Examples include

effective equipment maintenance programs, adequate housekeeping procedures, proper employee training, and development of emergency plans and strategies that deal with fire and explosion hazards. Such emergency plans can include use of company fire brigades and other available equipment such as fire trucks and water wagons, and the response of local fire departments.

(3) Determine whether risk reduction reduces risks to acceptable levels. If risks are within acceptable levels, no further action is required. If unacceptable risks still exist, then action is required either to further reduce hazards or to install fire detection/suppression equipment or a combination of both.

B.1.4.2 Fire detection and suppression equipment should be considered as follows:

(1) Identify available alternatives as follows:
   (a) Portable protection options include hand-portable extinguishers, hose reels and lines, wheeled extinguishers, and skid-mounted extinguishers. To handle difficult fires, larger capacity extinguishers that provide more agent, greater range, and longer discharge time are recommended for agent selection *(see B.1.5.1)*.
   (b) Fire detection devices can be used to provide early warning of fires, actuate a fire suppression system, shut down equipment, and operate other systems such as door closers and exhaust fans. *(For a discussion of detector and control options, selection, and placement, see B.1.5.3 and B.1.5.4.)*
   (c) Fixed system protection can be accomplished by local application, total flooding, or a combination of both, or automatic sprinklers. *(For agent selection, see B.1.5.1. For fixed fire suppression system options, see B.1.5.2.)*
(2) Compare capability with need. Mandatory requirements and identified needs should be matched with the most cost-effective approach to fire detection, fire suppression, or both.
(3) Select equipment. The selection of all equipment used for detection and suppression of fires in mining equipment should be based upon consideration of the environment where the equipment will function and should be tested. Testing should include provisions for determining the adequacy and durability of the equipment, and the manufacturer should demonstrate that such tests have been conducted.
(4) Evaluate. Determine whether risk reduction results in compliance with mandatory requirements or reduces risks to acceptable levels, or both. If risks are within acceptable levels, no further action is required. If unacceptable risks still exist, then action is required either to reduce hazards further or to install fire detection/suppression equipment or a combination of both.

NOTE: A more detailed discussion of fire suppression and detection equipment can be found in the references in Annex C and in NFPA 10.

B.1.5 Fire Protection Agents and Equipment.

B.1.5.1 The following extinguishants are commonly used in the mining industry for mobile equipment:

(1) Class A agents are as follows:
   (a) Dry chemicals (ABC) with ammonium phosphate as the basic ingredient
   (b) Foams such as protein, fluoroprotein, aqueous film forming, and medium and high expansion
   (c) Water
   (d) Clean agents (gaseous)
(2) Class B agents are dry chemicals (BC) with sodium bicarbonate, ammonium phosphate, potassium bicarbonate, urea-based potassium bicarbonate, or potassium chloride as the basic composition, as follows:
   (a) Foams such as protein, fluoroprotein, aqueous film forming, and medium and high expansion
   (b) Carbon dioxide
   (c) Water
   (d) Clean agents
(3) Class C agents are dry chemicals (ABC or BC) with sodium bicarbonate, ammonium phosphate, potassium bicarbonate, urea-based potassium bicarbonate, or potassium chloride as the basic composition, as follows:
   (a) Carbon dioxide
   (b) Water
   (c) Clean agents
(4) Class D agents are dry powder agents composed of sodium chloride or graphite with other particulate material added, as well as inert materials such as dry sand, foundry flux, and so on.

B.1.5.2 The design and layout of fixed fire suppression systems should be based upon the method of application of the fire suppressant to the area to be protected. Methods of delivery include the following:

(1) Local application consisting of a supply of suppressant permanently connected to a distribution system arranged to discharge onto a defined area or space
(2) Total flooding consisting of a supply of suppressant permanently connected to a distribution system arranged to discharge into an enclosed space
(3) A combination of B.1.5.2(1) and B.1.5.2(2) above
(4) Automatic sprinklers consisting of a supply of suppressant (normally water) permanently connected to a distribution system to discharge the suppressant

B.1.5.3 Detector options are as follows:

(1) Automatic fire detection devices are covered by *NFPA 72*. One fire detection device that is commonly used in self-propelled and mobile mining equipment but is not covered in *NFPA 72* is fusible plastic tube. It comprises a sensing element consisting of a plastic tube pressurized with inert gas. Heat from the fire causes the tube to burst, releasing the gas pressure and activating a mechanical pneumatic actuator.
(2) Consideration should be given to the physical configuration of the area to be protected when selecting and locating fire detectors. A detector's response time is dependent upon its type and proximity to a fire. For spacing, see *NFPA 72*. Other factors to be considered in fire detector placement are ambient temperature, climatic conditions, shock and vibration, air contamination, ventilation flows, and maintenance requirements.

B.1.5.4 Depending on mining equipment configuration, use, ground speed capability, degree of hazard enclosure, operating personnel locations, and other factors, consideration can be required of system control options such as the following:

(1) Discharge time delay
(2) Discharge abort switch

(3) Audible and visual alarms
(4) Pre-discharge alarm
(5) Detection circuit supervision

B.2 Electrical Ignition Hazards. Self-propelled and mobile surface mining equipment powered by electrical energy is normally supplied through portable electrical power cables carrying high-voltage, three-phase, ac power. Existing regulations require that the electrical system be designed to protect personnel by limiting the voltage rise of the machine frame, in the event of a ground fault, to a maximum of 100 volts. Protection on such electrical systems includes the following:

(1) Normal overcurrent protection
(2) Ground-fault current limitation (normally to about 15 amperes)
(3) Ground-fault overcurrent tripping (usually at about 7 amperes to 10 amperes)
(4) Monitoring of continuity of the ground conductor in the trailing cable and instantaneous tripping if continuity is lost
(5) Operational damage

Physical impact from external material at a chute or face, which can roll or slide onto equipment, can cause leaks in fuel or hydraulic lines as well as damage to electrical components and wiring.

Electrical systems having these protective features are singularly free of fires, as fault current is low and faults are cleared rapidly.

When equipment contains one or more transformers designed and installed to reduce the high voltage supplied through the portable cable to a lower utilization voltage, no requirements for ground-fault current limitation or tripping on ground-fault interruptors are necessary. All equipment on the machine is effectively frame grounded, and there is no risk to personnel due to frame voltage rise.

Alternatively, a ground detection system can be used on an ungrounded utilization voltage system, provided the first ground, which would cause an alarm, is found and repaired promptly. Use of a time delay to allow an orderly and safe shutdown of a machine followed by automatic removal of power from the grounded circuit is recommended.

B.2.1 Assess the consequences of fire, as follows:

(1) Determine whether personnel can be exposed to the effects of a fire. These effects could include the following:
    (a) Direct exposure of the operator or nearby personnel to heat, smoke, and toxic fire gases from the burning equipment.
    (b) Exposure of personnel located away from the equipment fire site to products of combustion by the mine ventilation.
    (c) Equipment fire spread to other combustibles such as timber supports, combustible minerals, explosives, and lubricants. Such fires can grow in intensity, producing increased quantities of toxic combustion products, complicating fire-fighting efforts, and interfering with evacuation and rescue operations.
    (d) The possibility of the equipment fire or secondary fires causing ventilation disturbances such as throttling or reversals, contaminating escapeways in an unpredictable manner.
(2) Determine the economic loss resulting from a fire on a piece of equipment, including both property damage and business interruption costs, and consider the following factors:
    (a) Fire involving a single piece of equipment could cause property damage and loss of production until the fire is extinguished and the equipment is repaired or replaced.
    (b) Fire spread to nearby combustible material, including combustible mineral seams, can have greater economic effects than the initial fire.

B.2.2 Determine the need for fire protection. If the risk analysis discloses unacceptable personnel risks, economic risks, or both, appropriate fire protection options should be determined.

B.2.3 Select appropriate fire protection option(s), as follows:

(1) Hazard reduction should be considered as follows:
    (a) Evaluate equipment to determine if the risk from the start or the spread of a fire can be reduced.
    (b) Reduce the threat of fire through implementation of company policies and procedures. Examples include effective equipment maintenance programs, adequate housekeeping procedures, proper employee training, development of emergency plans, and strategies that deal directly with fire.
    (c) Determine whether fire risk reduction practices reduce risks to acceptable levels. If risks are acceptable, no further action is necessary. If unacceptable risks still exist, action is needed either to reduce risks further or to install fire detection/suppression equipment, or a combination of both.
(2) Identify available fire detection and suppression equipment alternatives as follows:
    (a) Portable protection options include portable hand extinguishers, hose reels and lines, wheeled extinguishers, and skid-mounted extinguishers. For difficult fires, larger capacity extinguishers that provide more agent, greater range, and longer discharge time are recommended. *(See B.1.5.1 for agent selection.)*
    (b) Fire detection devices can be used to provide early warning of fires, actuate a fire suppression system, shut down equipment, and operate other fire control systems such as ventilation devices and fire doors. *(For a discussion of detector and control options, selection, and placement, see B.1.5.3 and B.1.5.4.)*
    (c) Fixed fire suppression systems should be considered as follows:
        i. Accomplish fixed system protection by local application, total flooding, a combination of both, or automatic sprinklers. *[See B.2.3(3) for agent selection. See B.2.3(3)(b)ii for fixed fire suppression options.]*
        ii. Compare capability with need. Identified needs should be matched with the most cost-effective approach to fire detection, fire suppression, or both.
        iii. Select equipment. The selection of all equipment used for all detection and suppression of fires in mining equipment should be based on consideration of the environment in which the equipment functions.
        iv. Evaluate fixed fire suppression systems. Determine whether fire risk reduction complies with mandatory requirements and reduces risks to acceptable levels. If risks are within acceptable levels, no further action is necessary. If not, additional action is needed either to reduce fire risks or to install fire detection/suppression equipment, or a combination of both.

(3) Fire protection agents and equipment should be considered as follows:

 (a) The following extinguishing agents commonly are used in the mining industry:

  i. Class A, including dry chemicals (ABC) with ammonium phosphate as the basic ingredient; foams such as protein, fluoroprotein, aqueous film-forming, and medium- and high-expansion; water; and water-based antifreeze solution

  ii. Class B, including dry chemicals (BC) with sodium bicarbonate, ammonium phosphate, potassium bicarbonate, urea-based potassium bicarbonate, or potassium chloride as the basic composition; foams such as protein, fluoroprotein, aqueous film-forming, and medium- and high-expansion; carbon dioxide; water spray or fog; and water-based antifreeze solution

  iii. Class C, including dry chemicals (ABC or BC) with sodium bicarbonate, ammonium phosphate, potassium bicarbonate, urea-based potassium bicarbonate, or potassium chloride as the basic composition; carbon dioxide; fixed water spray; and water fog

  iv. Class D, including dry powder agents composed of sodium chloride or graphite with other particulate material added and inert materials such as dry sand and foundry flux

 (b) Method of application should be as follows:

  i. Portable extinguisher of the hand-held or wheeled type or transportable systems consisting of a hose reel or rack, hose, and discharge nozzle connected to an extinguishing agent supply

  ii. Fixed systems, including local application consisting of a supply of extinguishing agent permanently connected to a distribution system, arranged to discharge onto a defined area or space; total flooding consisting of a supply of extinguishing agent permanently connected to a distribution system, arranged to discharge into an enclosed space; combination of B.2.3(3)(a)i and B.2.3(3)(a)ii; automatic sprinklers consisting of a supply of extinguishing agent (normally water) permanently connected to a distribution system to discharge the suppressant; water spray; and water fog

 (c) For guidance in the selection and placement of fire detectors, see *NFPA 72*. Some fire detectors used in conjunction with mining equipment, but not covered in *NFPA 72*, include the following:

  i. Fusible plastic tube: A sensing element consisting of a plastic tube pressurized with inert gas. Heat from the fire causes the tube to burst, releasing the gas pressure and activating a mechanical pneumatic actuator.

  ii. Thermistor strip: A line-type device with a sensing element consisting of a thin metal tube containing two electrical conductors. The conductors are separated by a thermistor material whose resistance (or capacitance) varies with temperature. By monitoring resistance (or capacitance) changes, corresponding temperature changes can be detected.

  iii. Metal hydride: A line-type device with a sensing element consisting of a thin metal tube containing a hydrogen-charged metal hydride wire. The tube is sealed at one end and is connected to a sensitive pressure switch at the other end. When exposed to the heat from a fire, copious amounts of hydrogen gas are released from the metal hydride wire, actuating the pressure switch.

  Consideration should be given to the physical configuration of the area or equipment to be protected when selecting and installing detectors. For spacing information, see *NFPA 72*. Among the factors affecting detector performance are its proximity to a fire, ambient temperatures, climatic conditions, shock and vibration, air contamination, ventilation flows, and maintenance requirements.

(4) Depending on mining equipment configuration, use, ground speed capability, enclosures, location of operating personnel, and other factors, the following special control options should be considered:

 (a) Mechanical or electrical equipment engine shutdown
 (b) Discharge time delay
 (c) Discharge abort switch
 (d) Audible and visual alarms
 (e) Pre-discharge alarm
 (f) Detection circuit supervision

Consideration should be given to the advisability of providing automatic engine shutdown on mobile equipment. Factors such as ground speed, slope braking capability, and availability of secondary steering as described in SAE J1511, *Steering for Off-Road, Rubber-Tired Machines*, should be included in this analysis.

NFPA® 130

Standard for

Fixed Guideway Transit and Passenger Rail Systems

2014 Edition

This edition of NFPA 130, *Standard for Fixed Guideway Transit and Passenger Rail Systems,* was prepared by the Technical Committee on Fixed Guideway Transit and Passenger Rail Systems and acted on by NFPA at its June Association Technical Meeting held June 10–13, 2013, in Chicago, IL. It was issued by the Standards Council on August 1, 2013, with an effective date of August 21, 2013, and supersedes all previous editions.

This edition of NFPA 130 was approved as an American National Standard on August 21, 2013.

Origin and Development of NFPA 130

The Fixed Guideway Transit Systems Technical Committee was formed in 1975 and immediately began work on the development of NFPA 130. One of the primary concerns of the committee in the preparation of this document centered on the potential for entrapment and injury of large numbers of people who routinely use these types of mass transportation facilities.

During the preparation of the first edition of this document, several significant fires occurred in fixed guideway systems, but fortunately the loss of life was limited. The committee noted that the minimal loss of life was due primarily to chance events more than any preconceived plan or the operation of protective systems.

The committee developed material on fire protection requirements to be included in NFPA 130, *Standard for Fixed Guideway Transit Systems*. This material was adopted by NFPA in 1983. The 1983 edition was partially revised in 1986 to conform with the NFPA *Manual of Style*. Incorporated revisions included a new Chapter 8; a new Appendix F, "Creepage Distance"; minor revisions to the first four chapters and to Appendices A, B, C, and E; and a complete revision of Appendix D.

The scope of the 1988 edition was expanded to include automated guideway transit (AGT) systems. The sample calculations in Appendix C were revised, and Appendix D was completely revised.

The 1990 edition included minor changes to integrate provisions and special requirements for AGT systems into the standard. Table 1 from Appendix D was moved into Chapter 4, "Vehicles," and new vehicle risk assessment material was added to Appendix D.

Definitions for *enclosed station* and *open station* were added in the 1993 edition, along with minor changes to Chapters 2 and 3; the 1995 edition made minor changes to Chapters 1, 2, and 3.

The 1997 edition included a new chapter on emergency ventilation systems for transit stations and trainways. A new Appendix B addressing ventilation replaced the previous Appendix B, "Air Quality Criteria in Emergencies." Also, the first three sections of Chapter 6 (renumbered as Chapter 7 in the 1997 edition), "Emergency Procedures," were revised, and several new definitions were added.

The 2000 edition of NFPA 130 addressed passenger rail systems in addition to fixed guideway transit systems. The document was retitled to reflect that addition, and changes were made throughout the document to incorporate passenger rail requirements. Additionally, much of Chapter 2 was rewritten to incorporate changes that were made to the egress calculations in NFPA *101*®, *Life Safety Code*®. The examples in Appendix C were modified using the new calculation methods. The protection requirements for Chapter 3 were modified, addressing emergency lighting and standpipes. Chapter 4 also was modified to clarify and expand the emergency ventilation requirements.

NFPA and National Fire Protection Association are registered trademarks of the National Fire Protection Association, Quincy, Massachusetts 02169.

The 2003 edition was reformatted in accordance with the 2003 *Manual of Style for NFPA Technical Committee Documents*. Beyond those editorial changes, there were technical revisions to the egress requirements and calculations for stations. The chapter on vehicles was extensively rewritten to include a performance-based design approach to vehicle design as well as changes to the traditional prescriptive-based requirements.

The 2007 edition included revisions affecting station egress calculations, the use of escalators in the means of egress, vehicle interior fire resistance, and power supply to tunnel ventilation systems. The chapter on vehicle maintenance facilities was removed because requirements for that occupancy are addressed in other codes; the performance-based vehicle design requirements were substantially revised to more accurately address the unique qualities of rail vehicles.

The 2010 edition of NFPA 130 included provisions that allowed elevators to be counted as contributing to the means of egress in stations. The 2010 edition also contained revisions relating to escalators, doors, gates, and turnstile-type fare equipment. The units in the standard were updated in accordance with the 2004 *Manual of Style for NFPA Technical Committee Documents*. Several fire scenarios were added to Annex A to provide guidance on the types of fires that can occur in vehicles, stations, and the operating environment as well.

The 2014 edition of NFPA 130 includes substantial re-organization of Chapters 5 and 6 for consistency and consolidation of wire and cable requirements into a new Chapter 12. Other changes include reconciliation of terminology related to enclosed trainways and engineering versus fire hazard analysis; revisions to interior finish requirements; revisions to requirements for prevention of flammable and combustible liquids intrusion in Chapters 5 and 6; and improvements to Annex C.

Technical Committee on Fixed Guideway Transit and Passenger Rail Systems

Sandra Stanek, NFPA Staff Liaison

This list represents the membership at the time the Committee was balloted on the final text of this edition. Since that time, changes in the membership may have occurred. A key to classifications is found at the back of the document.

NOTE: Membership on a committee shall not in and of itself constitute an endorsement of the Association or any document developed by the committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents pertaining to fire safety requirements for underground, surface, and elevated fixed guideway transit and passenger rail systems including stations, trainways, emergency ventilation systems, vehicles, emergency procedures, communications and control systems and for life safety from fire and fire protection in stations, trainways, and vehicles. Stations shall pertain to stations accommodating occupants of the fixed guideway transit and passenger rail systems and incidental occupancies in the stations.

NFPA 130

Standard for

Fixed Guideway Transit and Passenger Rail Systems

2014 Edition

IMPORTANT NOTE: This NFPA document is made available for use subject to important notices and legal disclaimers. These notices and disclaimers appear in all publications containing this document and may be found under the heading "Important Notices and Disclaimers Concerning NFPA Documents." They can also be obtained on request from NFPA or viewed at www.nfpa.org/disclaimers.

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates that explanatory material on the paragraph can be found in Annex A.

Changes other than editorial are indicated by a vertical rule beside the paragraph, table, or figure in which the change occurred. These rules are included as an aid to the user in identifying changes from the previous edition. Where one or more complete paragraphs have been deleted, the deletion is indicated by a bullet (•) between the paragraphs that remain.

A reference in brackets [ ] following a section or paragraph indicates material that has been extracted from another NFPA document. As an aid to the user, the complete title and edition of the source documents for extracts in mandatory sections of the document are given in Chapter 2 and those for extracts in informational sections are given in Annex H. Extracted text may be edited for consistency and style and may include the revision of internal paragraph references and other references as appropriate. Requests for interpretations or revisions of extracted text shall be sent to the technical committee responsible for the source document.

Information on referenced publications can be found in Chapter 2 and Annex H.

Chapter 1 Administration

1.1 Scope.

1.1.1* This standard shall cover life safety from fire and fire protection requirements for fixed guideway transit and passenger rail systems, including, but not limited to, stations, trainways, emergency ventilation systems, vehicles, emergency procedures, communications, and control systems.

1.1.2 Fixed guideway transit and passenger rail stations shall pertain to stations accommodating only passengers and employees of the fixed guideway transit and passenger rail systems and incidental occupancies in the stations. This standard establishes minimum requirements for each of the identified subsystems.

1.1.3 This standard shall not cover requirements for the following:

(1) Conventional freight systems
(2) Buses and trolley coaches
(3) Circus trains
(4) Tourist, scenic, historic, or excursion operations
(5) Any other system of transportation not included in the definition of *fixed guideway transit system (see 3.3.52.1)* or *passenger rail system (see 3.3.52.2)*
(6)*Shelter stops

1.1.4 To the extent that a system, including those listed in 1.1.3(1) through 1.1.3(6), introduces hazards of a nature similar to those addressed herein, this standard shall be permitted to be used as a guide.

1.2 Purpose. The purpose of this standard shall be to establish minimum requirements that will provide a reasonable degree of safety from fire and its related hazards in fixed guideway transit and passenger rail system environments.

1.3 Application.

1.3.1 This standard shall apply to new fixed guideway transit and passenger rail systems and to extensions of existing systems.

1.3.2 The portion of the standard dealing with emergency procedures shall apply to new and existing systems.

1.3.3* The standard also shall be used for purchases of new rolling stock and retrofitting of existing equipment or facilities except in those instances where compliance with the standard will make the improvement or expansion incompatible with the existing system.

1.3.4 This standard shall also apply as a basis for fixed guideway transit and passenger rail systems where nonelectric and combination electric-other (such as diesel) vehicles are used. Where such vehicles are not passenger-carrying vehicles or are buses or trolley coaches, the standard shall not apply to those vehicles but shall apply to the fixed guideway transit and passenger rail systems in which such vehicles are used.

1.4* Equivalency. Nothing in this standard is intended to prevent or discourage the use of new methods, materials, or devices, provided that sufficient technical data are submitted to the authority having jurisdiction to demonstrate that the new method, material, or device is equivalent to or superior to the requirements of this standard with respect to fire performance and life safety.

1.4.1 Technical Documentation. Technical documentation shall be submitted to the authority having jurisdiction to demonstrate equivalency.

1.4.2 Approval. The new methods, materials, or devices shall be approved for the intended purpose.

1.4.3* Equivalent Compliance. Alternative systems, methods, materials, or devices approved as equivalent shall be recognized as being in compliance with this standard.

1.5 Units and Formulas.

1.5.1 SI Units. The metric units of measurement in this standard are in accordance with the International System of Units (SI).

1.5.2 Primary and Equivalent Values. If a value for a measurement as given in this standard is followed by an equivalent value in other units, the first stated value shall be regarded as the requirement. A given equivalent value might be approximated.

Chapter 2 Referenced Publications

2.1 General. The documents or portions thereof listed in this chapter are referenced within this standard and shall be considered part of the requirements of this document.

Chapter 3 Definitions

3.1 General. The definitions contained in this chapter shall apply to the terms used in this standard. Where terms are not defined in this chapter or within another chapter, they shall be defined using their ordinarily accepted meanings within the context in which they are used. *Merriam-Webster's Collegiate Dictionary*, 11th edition, shall be the source for the ordinarily accepted meaning.

3.2 NFPA Official Definitions.

3.2.1* Approved. Acceptable to the authority having jurisdiction.

3.2.2* Authority Having Jurisdiction (AHJ). An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

3.2.3 Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

3.2.4* Listed. Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

3.2.5 Shall. Indicates a mandatory requirement.

3.2.6 Should. Indicates a recommendation or that which is advised but not required.

3.3 General Definitions.

3.3.1* Airflow Control Devices. Nontraditional equipment used to minimize tunnel airflow, including air curtains, barriers, brattices, tunnel doors, downstands, enclosures, tunnel gates, and so forth.

3.3.2 Ancillary Area/Ancillary Space. The nonpublic areas or spaces of the stations usually used to house or contain operating, maintenance, or support equipment and functions.

3.3.3 Authority. The agency legally established and authorized to operate a fixed guideway transit and/or passenger rail system.

3.3.4 Backlayering. The reversal of movement of smoke and hot gases counter to the direction of the ventilation airflow.

3.3.5* Blue Light Station. A location along the trainway, indicated by a blue light, where a person can communicate with the operations control center and disconnect traction power.

3.3.6 Building. Any structure or group of structures in which fixed guideway transit and/or passenger rail vehicles are stored or maintained, including those in which inspection and service functions are performed, and other ancillary structures, such as substations and air-conditioning or ventilation facilities.

3.3.7 Combustible Load of a Vehicle. The total value of heat energy that can be released through complete combustion of the components of a vehicle or fuel, expressed in joules [British thermal units (Btu)].

3.3.8 Command Post (CP). The location at the scene of an emergency where the incident commander is located and where command, coordination, control, and communications are centralized. [**402,** 2013]

3.3.9 Communications. Radio, telephone, and messenger services throughout the system and particularly at the operations control center and command post.

3.3.10 Computational Fluid Dynamics. A solution of fundamental equations of fluid flow using computer techniques allowing the engineer to identify velocities, pressures, temperatures, and so forth.

3.3.11* Concourse. Intermediate level(s) or area(s) connecting a station platform(s) to a public way via stairs, escalators, or corridors.

3.3.12 Critical Radiant Flux. The level of incident radiant heat energy in units of W/cm^2 on a floor covering system at the most distant flameout point. [**253,** 2011]

3.3.13 Critical Velocity. The minimum steady-state velocity of the ventilation airflow moving toward the fire within a tunnel or passageway that is required to prevent backlayering at the fire site.

3.3.14 Emergency Procedures Plan. A plan that is developed by the authority with the cooperation of all participating agencies and that details specific actions required by all those who will respond during an emergency.

3.3.15* Engineering Analysis. A system analysis that evaluates all the various factors of relative to specific objectives for system performance.

3.3.15.1* ***Fire Hazard Analysis.*** A specific type of engineering analysis relative to the contribution of a material, component, or assembly to the overall fire hazard and the estimation of the potential severity of fires that can develop under defined fire scenarios.

3.3.16 Equivalency. An alternative means of providing an equal or greater degree of safety than that afforded by strict conformance to prescribed codes and standards.

3.3.17 Fire Command Center. The principal attended or unattended room or area where the status of the detection, alarm communications, control systems, and other emergency systems is displayed and from which the system(s) can be manually controlled. [**72**, 2013]

3.3.18 Fire Emergency. The existence of, or threat of, fire or the development of smoke or fumes, or any combination thereof, that demands immediate action to correct or alleviate the condition or situation. [**502,** 2014]

3.3.19 Fire Growth Rate. Rate of change of the heat release rate. Some factors that affect the fire growth rate are exposure, geometry, flame spread, and fire barriers.

3.3.20 Fire Load.

3.3.20.1* ***Effective Fire Load.*** The portion of the total fire load (in joules or Btu) under a given, specific fire scenario of a certain fuel package that would be expected to be released in a design fire incident.

3.3.20.2* ***Total Fire Load.*** The total heat energy (in joules or Btu) of all combustibles available from the constituent materials of a certain fuel package.

3.3.21 Fire Smoke Release Rate. Rate of smoke release for a given fire scenario expressed as a function of time [in m^2/sec (ft^2/sec)].

3.3.22 Flaming Dripping. Periodic dripping of flaming material from the site of material burning or material installation.

3.3.23 Flaming Running. Continuous flaming material leaving the site of material burning or material installation.

3.3.24 Guideway. That portion of the fixed guideway transit or passenger rail system included within right-of-way fences, outside lines of curbs or shoulders, underground tunnels and stations, cut or fill slopes, ditches, channels, and waterways and including all appertaining structures.

3.3.25 Hazard. Real or potential condition that can cause injury.

3.3.26 Headway. The interval of time between the arrivals of consecutive trains at a platform in a station.

3.3.27* Heat Release Rate (HRR). The rate at which heat energy is generated by burning. [**921,** 2011]

3.3.27.1 ***Average Heat Release Rate (HRR_{180}).*** The average heat release rate per unit area, over the time period starting at time to ignition and ending 180 seconds later, as measured in ASTM E 1354 (kW/m^2).

3.3.27.2 ***Fire Heat Release Rate for Ventilation Calculations.*** Rate of energy release for a given fire scenario expressed as a function of time [W (Btu/s)].

3.3.28 Incident Commander (IC). The individual responsible for all incident activities, including the development of strategies and tactics and the ordering and the release of resources. [**472,** 2013]

• **3.3.29 Noncombustible (Material).** See Section 4.7.

3.3.30 Nonmechanical Emergency Ventilation System. A system of smoke reservoirs, smoke vents, and/or dampers that are designed to support the tenability criteria without the use of fans.

3.3.31 Occupancy.

3.3.31.1 ***Incidental Occupancies Within Stations.*** The use of a portion of the station by others who are neither transit system employees nor passengers and where such space remains under the control of the system-operating authority.

3.3.31.2 ***Nonsystem Occupancy.*** An occupancy not under the control of the system-operating authority.

3.3.32 Operations Control Center. The operations center where the authority controls and coordinates the systemwide movement of passengers and trains from which communication is maintained with supervisory and operating personnel of the authority and with participating agencies when required.

3.3.33 Participating Agency. A public, quasipublic, or private agency that has agreed to cooperate with and assist the authority during an emergency.

3.3.34 Passenger Load.

3.3.34.1 ***Detraining Load.*** The number of passengers alighting from a train at a platform.

3.3.34.2 ***Entraining Load.*** The number of passengers boarding a train at a platform.

3.3.34.3 ***Link Load.*** The number of passengers traveling between two stations on board a train or trains.

3.3.35 Point of Safety. A point of safety is one of the following: (1) an enclosed exit that leads to a public way or safe location outside the station, trainway, or vehicle; (2) an at-grade point beyond the vehicle, enclosing station, or trainway; (3) any other approved location.

3.3.36 Power Station. An electric-generating plant for supplying electrical energy to the system.

3.3.37 Power Substation. Location of electric equipment that does not generate electricity but receives and converts or transforms generated energy to usable electric energy.

3.3.38 Radiant Panel Index (I_s). The product of the flame spread factor (F_s) and the heat evolution factor (Q_s), as determined in ASTM E 162.

3.3.39 Replace in Kind. As applied to vehicles and facilities, to furnish with new parts or equipment of the same type but not necessarily of identical design.

3.3.40 Retrofit. As applied to vehicles and facilities, to furnish with new parts or equipment to constitute a deliberate modification of the original design (as opposed to an overhaul or a replacement in kind).

3.3.41 Smoke Obscuration. The reduction of light transmission by smoke, as measured by light attenuation. [**270,** 2013]

3.3.42 Specific Extinction Area. A measure of smoke obscuration potential per unit mass burnt, determined as the product of the specific extinction coefficient and the volumetric mass flow rate, divided by the mass loss rate [m/kg (ft/lb)].

3.3.43 Specific Optical Density (D_s). The optical density, as measured in ASTM E 662, over unit path length within a chamber of unit volume, produced from a specimen of unit surface area, that is irradiated by a heat flux of 2.5 W/cm^2 for a specified period of time.

3.3.44 Station. A place designated for the purpose of loading and unloading passengers, including patron service areas and ancillary spaces associated with the same structure.

3.3.44.1 ***Enclosed Station.*** A station or portion thereof that does not meet the definition of an open station.

3.3.44.2* ***Open Station.*** A station that is constructed such that it is directly open to the atmosphere and smoke and heat are allowed to disperse directly into the atmosphere.

3.3.45 Station Platform. The area of a station immediately adjacent to a guideway, used primarily for loading and unloading passengers.

3.3.46 Structure.

3.3.46.1 ***Elevated Structure.*** Any structure not otherwise defined as a surface or underground structure.

3.3.46.2 ***Surface Structure.*** Any at-grade or unroofed structure other than an elevated or underground structure.

3.3.47 System. See 3.3.52.1, Fixed Guideway Transit System, or 3.3.52.2, Passenger Rail System.

3.3.48 Tenable Environment. An environment that permits the self-rescue or survival of occupants.

3.3.49 Tourist, Scenic, Historic, or Excursion Operations. Railroad operations, often using antiquated equipment, that are principally intended to carry passengers traveling for pleasure purposes.

3.3.50 Track.

3.3.50.1 ***Storage Track.*** A portion of the trainway used for temporary storage or light cleaning of trains and not intended to be used for trains occupied by passengers.

3.3.50.2 ***Tail Track.*** A portion of dead-end trainway used for temporary storage, turn-around, or light cleaning of trains and not intended to be used for trains occupied by passengers.

3.3.51 Trainway. That portion of the system in which the vehicles operate.

3.3.52 Transportation Systems.

3.3.52.1 ***Fixed Guideway Transit System.*** An electrified transportation system, utilizing a fixed guideway, operating on right-of-way for the mass movement of passengers within a metropolitan area, and consisting of its fixed guideways, transit vehicles, and other rolling stock; power systems; buildings; stations; and other stationary and movable apparatus, equipment, appurtenances, and structures.

3.3.52.1.1 ***Automated Fixed Guideway Transit System.*** A fixed guideway transit system that operates fully automated, driverless vehicles along an exclusive right-of-way.

3.3.52.2 ***Passenger Rail System.*** A transportation system, utilizing a rail guideway, operating on right-of-way for the movement of passengers within and between metropolitan areas, and consisting of its rail guideways, passenger rail vehicles, and other rolling stock; power systems; buildings; stations; and other stationary and movable apparatus, equipment, appurtenances, and structures.

3.3.53 Vehicle.

3.3.53.1 ***Fixed Guideway Transit Vehicle.*** An electrically propelled passenger-carrying vehicle characterized by high acceleration and braking rates for frequent starts and stops and fast passenger loading and unloading.

3.3.53.2 ***Passenger Rail Vehicle.*** A vehicle and/or power unit running on rails used to carry passengers and crew.

Chapter 4 General

4.1 Fire Safety of Systems.

4.1.1 Fire safety of systems shall be achieved through a composite of facility design, operating equipment, hardware, procedures, and software subsystems that are integrated to protect life and property from the effects of fire.

4.1.2 The level of fire safety desired for the whole system shall be achieved by integrating the required levels for each subsystem.

4.2 Goals.

4.2.1* The goals of this standard shall be to provide an environment for occupants of fixed guideway and passenger rail system elements that is safe from fire and similar emergencies to a practical extent based on the following measures:

(1) Protection of occupants not intimate with the initial fire development
(2) Maximizing the survivability of occupants intimate with the initial fire development

4.2.2 This standard is prepared with the intent of providing minimum requirements for those instances where noncombustible materials (as defined in Section 4.7) are not used due to other consideration in the design and construction of the system elements.

4.3 Objectives.

4.3.1 Occupant Protection. Systems shall be designed, constructed, and maintained to protect occupants who are not intimate with the initial fire development for the time needed to evacuate or relocate them or to defend such occupants in place during a fire or fire-related emergency.

4.3.2 Structural Integrity. Structural integrity of stations, trainways, and vehicles shall be maintained for the time needed to evacuate, relocate, or defend in place occupants who are not intimate with the initial fire development.

4.3.3 Systems Effectiveness. Systems utilized to achieve the goals stated in Section 4.2 shall be effective in mitigating the hazard or condition for which they are being used, shall be reliable, shall be maintained to the level at which they were designed to operate, and shall remain operational.

4.4* Assumption of a Single Fire Event. The protection methods described in this standard shall assume a single fire event from a single fire source.

4.5* Shared Use by Freight Systems. Where passenger and freight systems are operated concurrently through or adjacent to stations and trainways, the design of the station and trainway fire-life safety and fire protection systems shall consider the hazards associated with both uses, as approved.

4.6* Fire Scenarios. Design scenarios shall consider the location and size of a fire or a fire-related emergency.

4.7* Noncombustible Material.

4.7.1* A material that complies with any of the following shall be considered a noncombustible material: [**101:**4.6.13.1]

(1) A material that, in the form in which it is used and under the conditions anticipated, will not ignite, burn, support combustion, or release flammable vapors, when subjected to fire or heat. [**101:**4.6.13.1(1)]
(2) A material that is reported as passing ASTM E 136. [**101:** 4.6.13.1(2)]
(3) A material that is reported as complying with the pass/fail criteria of ASTM E 136 when tested in accordance with the test method and procedure in ASTM E 2652. [**101:**4.6.13.1(3)]

4.8* Fire-Life Safety System Integrity. No part of the fire-life safety system critical to the intended system function that addresses an emergency shall be vulnerable to the emergency that it is supposed to address.

Chapter 5 Stations

5.1 General.

5.1.1 Applicability.

5.1.1.1 This chapter shall apply to all portions of stations.

5.1.2* Relationship to Local Codes.

5.1.2.1 The requirements in this chapter shall supplement the requirements of the locally applicable codes for the design and construction of stations.

5.1.2.2 Where the requirements in this chapter do not address a specific feature of fire protection or life safety, the requirements of the local codes shall be considered applicable.

5.1.3 Use and Occupancy.

5.1.3.1 The primary purpose of a station shall be for the use of the passengers who normally stay in a station structure for a period of time no longer than that necessary to wait for and enter a departing passenger-carrying vehicle or to exit the station after arriving on an incoming passenger-carrying vehicle.

5.1.3.2 Where contiguous nonsystem occupancies share common space with the station, where incidental occupancies are within the station, or where the station is integrated into a building used for nonsystem occupancy of which is for neither fixed guideway transit nor passenger rail, special considerations beyond this standard shall be necessary.

5.1.3.3 A station shall also be for the use of employees whose work assignments require their presence in the station structures.

5.2 Construction.

5.2.1 Safeguards During Construction.

5.2.1.1 During the course of construction, provisions of NFPA 241 shall apply except as modified herein.

5.2.1.2 Where access for fire fighting is restricted, standpipes sized for water flow and pressure for the maximum predicted construction fire load shall be installed to within 61 m (200 ft) of the most remote portion of the station.

5.2.1.3 The flow and pressure required at the outlet shall be approved.

5.2.1.4* Illumination levels within construction areas of enclosed stations shall not be less than 2.7 lx (0.25 ft-candles) at the walking surface.

5.2.2 Construction Type.

5.2.2.1 Building construction for all new enclosed stations shall be not less than Type I or Type II or combinations of Type I and Type II noncombustible construction as defined in NFPA 220, in accordance with the requirements of NFPA *101*, Chapter 12, for the station configuration or as determined by fire hazard analysis of potential fire exposure hazards to the structure.

5.2.2.2 Other types of construction as defined in NFPA 220 shall be permitted for open stations in accordance with the provisions of NFPA *101*, Chapter 12, for corresponding station configurations.

5.2.3 Flammable and Combustible Liquids Intrusion.

5.2.3.1 General. Protection of underground system structures against the accidental intrusion of flammable and combustible liquids shall be provided in accordance with this section.

5.2.3.2 Vehicle Roadway Terminations. Vent or fan shafts utilized for ventilation of underground system structures shall not terminate at grade on any vehicle roadway.

5.2.3.3 Median and Sidewalk Terminations. Vent and fan shafts shall be permitted to terminate in the median strips of divided highways, on sidewalks designed to accept such shafts, or in open space areas, provided that the grade level of the median strips, sidewalk, or open-space meets the following conditions:

(1) It is at a higher elevation than the surrounding grade level.
(2) It is separated from the roadway by a concrete curb at least 150 mm (6 in.) in height.

5.2.4 Compartmentation.

5.2.4.1 Interconnected Floor Levels. Interconnection between floor levels in stations shall be permitted as follows:

(1)*Stairs and escalators used by passengers shall not be required to be fire-separated.
(2) Public areas on different levels in open stations are permitted to be interconnected.
(3) Public areas on different levels in enclosed stations shall be permitted to be interconnected, provided fire separation is not required for smoke control or other fire protection purposes.

5.2.4.2* Separation Between Public and Nonpublic Floor Areas. All public areas shall be fire-separated from adjacent nonpublic areas.

5.2.4.3 Ancillary Spaces. Fire resistance ratings of separations between ancillary occupancies shall be established as required by NFPA *101* and in accordance with ASTM E 119 and ANSI/UL 263.

5.2.4.4* Agents' and Information Booths. Agents' or information booths shall comply with the following:

(1) Agents' or information booths shall be constructed of noncombustible materials.
(2) Booths used only as agents' and information booths shall not be required to be fire-separated from public station areas.

5.2.4.5* Separation Between System and Nonsystem Occupancies. All station public areas shall be fire separated from adjacent non-system occupancies.

5.2.5 Interior Finish.

5.2.5.1 Materials used as interior wall and ceiling finish in enclosed stations shall be noncombustible except as permitted in the following:

(1) Except as required for materials listed in (2), materials exhibiting a flame spread index not exceeding 25 and a smoke developed index not exceeding 450 when tested in accordance with ASTM E 84 shall be permitted as interior wall and ceiling finish in enclosed stations.
(2) The following materials shall not be used as interior wall or ceiling finish, whether exposed or covered by a textile or vinyl facing, unless they are tested in accordance with NFPA 286 and meet the requirements of (3):
    (a) Foam plastic insulation
    (b) Textile wall or ceiling coverings
    (c) Polypropylene
    (d) High-density polyethylene
(3) Materials in accordance with NFPA 286, and meeting the following requirements shall be permitted as interior wall and ceiling finish in enclosed stations.
    (a) Flames shall not spread to the ceiling during the 40 kW (135 kBtu/hr) exposure.
    (b) Flames shall not spread to the outer extremities of the sample on any wall or ceiling.
    (c) Flashover, as described in NFPA 286, shall not occur.
    (d) The peak heat release rate shall not exceed 800 kW (2730 kBtu/hr).
    (e) The total smoke released throughout the test shall not exceed 1000 m^2 (10,764 ft^2).

5.2.5.2 Materials used as interior floor finish materials in enclosed stations shall be noncombustible or shall exhibit a critical radiant flux not less than 0.8 W/cm^2 (0.7 $Btu/ft^2 \cdot sec$) when tested in accordance with ASTM E 648.

5.2.5.3 Materials used as interior finish in open stations shall comply with the requirements of NFPA *101*, Chapter 12.

5.2.6 Combustible Furnishings and Contents.

5.2.6.1* Where combustible furnishings or contents not specifically addressed in this standard are installed in a station, a fire hazard analysis shall be conducted to determine that the level of occupant fire safety is not adversely affected by the furnishings and contents.

5.2.6.2* Permanent rubbish containers in the station shall be manufactured of noncombustible materials.

5.2.6.3 Seating furniture in stations shall be noncombustible, or it shall have limited rates of heat release when tested in accordance with ASTM E 1537, as follows:

(1) The peak rate of heat release for a single seating furniture item shall not exceed 80 kW (270 kBtu/hr).
(2) The total energy released by a single seating furniture item during the first 10 minutes of the test shall not exceed 25 MJ (23,700 Btu).

5.2.6.4 Lockers shall be constructed of noncombustible materials.

5.3* Means of Egress.

5.3.1* General.

5.3.1.1 The provisions for means of egress for a station shall comply with Chapters 7 and 12 of NFPA *101*, except as herein modified.

5.3.1.2 For a station, the design of the means of egress shall be based on an emergency condition requiring evacuation of the train(s) and station occupants to a point of safety.

5.3.2 Occupant Load.

5.3.2.1* The occupant load for a station shall be based on the train load of trains simultaneously entering the station on all tracks in normal traffic direction plus the simultaneous entraining load awaiting trains.

(1) The train load shall consider only one train at any one track.
(2) The basis for calculating train and entraining loads shall be the peak period ridership figures as projected for design of a new system or as updated for an operating system.

5.3.2.2* For station(s) servicing areas such as civic centers, sports complexes, and convention centers, the peak ridership figures shall consider events that establish occupant loads not included in normal passenger loads.

5.3.2.3 At multilevel, multiline, or multiplatform stations, occupant loads shall be determined as follows:

(1) The maximum occupant load for each platform shall be considered separately for the purpose of sizing the means of egress from that platform.
(2)*Simultaneous loads shall be considered for all egress routes passing through each level of that station.

5.3.2.4 Where an area within a station is intended for use by other than passengers or employees, the following parameters shall apply:

(1) The occupant load for that area shall be determined in accordance with the provisions of NFPA *101* as appropriate for the use.
(2) The additional occupant load shall be included in determining the required egress from that area.
(3) The additional occupant load shall be permitted to be omitted from the station occupant load where the area has independent means of egress of sufficient number and capacity.

5.3.2.5* Calculation of Platform Occupant Load. The platform occupant load for each platform in a station shall be the maximum peak period occupant load calculated according to the following:

(1) The peak period occupant load for each platform shall be based on the simultaneous evacuation of the entraining load and the train load for that platform in the peak period.
(2) The entraining load for each platform shall be the sum of the entraining loads for each track serving that platform.
(3)*The entraining load for each track shall be based on the entraining load per train headway factored to account for service disruptions and system reaction time.
(4)*Where a platform serves more than one line on one track, the calculation of entraining load shall consider the combined effect of accumulation for each of the lines served.
(5) The train load for each platform shall be the sum of the train loads for each track serving that platform.
(6) The train load for each track shall be based on the train load per train headway factored to account for service disruptions and system reaction time.
(7) The maximum train load at each track shall be the maximum passenger capacity for the largest capacity train operating on that track during the peak period.

5.3.3* Capacity and Location of Means of Egress.

5.3.3.1* Platform Evacuation Time. There shall be sufficient egress capacity to evacuate the platform occupant load as defined in 5.3.2.5 from the station platform in 4 minutes or less.

5.3.3.2* Evacuation Time to a Point of Safety. The station shall be designed to permit evacuation from the most remote point on the platform to a point of safety in 6 minutes or less.

5.3.3.3 For open stations where the concourse is below or protected from the platform by distance or materials as determined by an appropriate engineering analysis, that concourse shall be permitted to be defined as a point of safety.

5.3.3.4 For enclosed stations equipped with an emergency ventilation system designed in accordance with Chapter 7 and where the emergency ventilation system provides protection for the concourse from exposure to the effects of a train fire at the platform as confirmed by engineering analysis, that concourse is permitted to be defined as a point of safety.

5.3.3.5 Travel Distance. The maximum travel distance on the platform to a point at which a means of egress route leaves the platform shall not exceed 100 m (325 ft).

5.3.3.6* Common Path of Travel. A common path of travel from the ends of the platform shall not exceed 25 m (82 ft) or one car length, whichever is greater.

5.3.3.7 Alternate Egress. At least two means of egress remote from each other shall be provided from each station platform as follows:

(1)*A means of egress used as a public circulation route shall be permitted to provide more than 50 percent of the required egress capacity from a station platform or other location.
(2) Means of egress from separate platforms shall be permitted to converge.
(3) Where means of egress routes from separate platforms converge, the subsequent capacity of the egress route shall be sufficient to maintain the required evacuation time from the incident platform.

5.3.3.8* Engineering Analysis. Modification of the evacuation times and travel distances shall be permitted based on an engineering analysis by evaluating material heat release rates, station geometry, and emergency ventilation systems.

5.3.4* Platforms, Corridors, and Ramps.

5.3.4.1* A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.

5.3.4.3 The maximum means of egress capacity of platforms, corridors, and ramps shall be computed at 0.0819 p/mm-min (2.08 p/in.-min).

5.3.4.4* The maximum means of egress travel speed along platforms, corridors, and ramps shall be computed at 37.7 m/min (124 ft/min).

5.3.4.5* The means of egress travel speed for concourses and other areas where a lesser pedestrian density is anticipated shall be computed at 61.0 m/min (200 ft/min).

5.3.5 Stairs and Escalators.

5.3.5.1 Stairs and escalators permitted by 5.2.4.1 to be unenclosed shall be permitted to be counted as contributing to the means of egress capacity in stations as detailed in 5.2.2 and 5.3.3.

5.3.5.2 Stairs in the means of egress shall be a minimum of 1120 mm (44 in.) wide.

5.3.5.3* Capacity and travel speed for stairs and escalators shall be computed as follows:

(1) Capacity — 0.0555 p/mm-min (1.41 p/in.-min)
(2)*Travel speed — 14.6 m/min (48 ft/min) (indicates vertical component of travel speed)

5.3.5.4* Escalators shall not account for more than one-half of the means of egress capacity at any one level except as permitted by 5.3.5.5.

5.3.5.5 Escalators shall be permitted to account for more than one-half of the required means of egress capacity at any one level where the following criteria are met:

(1) The escalators are capable of being remotely brought to a stop in accordance with the requirements of 5.3.5.7(3)(b), 5.3.5.7(4), and 5.3.5.7(5).

(2) A portion of the means of egress capacity from each station level is stairs.
(3) For enclosed stations, at least one enclosed exit stair or exit passageway provides continuous access from the platforms to the public way.

5.3.5.6* In calculating the egress capacity of escalators, the following criteria shall be met:

(1) One escalator at each level shall be considered as being out of service.
(2) The escalator chosen shall be the one having the most adverse effect upon egress capacity.

5.3.5.7 Where escalators are permitted as a means of egress in stations, the following criteria shall be met:

(1)*The escalators shall be constructed of noncombustible materials.
(2)*Escalators running in the direction of egress shall be permitted to remain operating.
(3) Escalators running reverse to the direction of egress shall be capable of being stopped locally and remotely as follows:
   (a) Locally by a manual stopping device at the escalator
   (b) Remotely by one of the following:
      i. A manual stopping device at a remote location
      ii. As part of a pre-planned evacuation response
(4)*Where provision is made for remote stopping of escalators counted as means of egress, one of the following shall apply:
   (a) The stop shall be delayed until it is preceded by a minimum 15-second audible signal or warning message sounded at the escalator
   (b) Where escalators are equipped with the necessary controls to decelerate in a controlled manner under the full rated load, the stop shall be delayed for at least 5 seconds before beginning deceleration, and the deceleration, rate shall be no greater than 0.052 m/sec^2 (0.17 ft/sec^2).
(5) Where an audible signal or warning message is used, the following shall apply:
   (a) The signal or message shall have a sound intensity that is at least 15 dBA above the average ambient sound level for the entire length of the escalator.
   (b) The signal shall be distinct from the fire alarm signal.
   (c) The warning message shall meet audibility and intelligibility requirements.

5.3.5.8 Escalators with or without intermediate landings shall be acceptable as a means of egress, regardless of vertical rise.

5.3.5.9 Escalators exposed to the outdoor environment shall be provided with slip-resistant landing and floor plates, and if they are exposed to freezing temperatures, the landing and floor plates and the steps shall be heated to prevent the accumulation of ice and snow.

5.3.5.10 Stopped escalators shall be permitted to be started in the direction of egress in accordance with the requirements for stopping of escalators described in 5.3.5.7(3), 5.3.5.7(4), and 5.3.5.7(5), provided that the escalators can be restarted in a fully loaded condition and that passengers are given warning.

5.3.6 Elevators.

5.3.6.1 Elevators meeting the requirements of 5.3.6.2 through 5.3.6.4 shall be permitted to account for part of the means of egress capacity in stations.

5.3.6.2 Capacity. Where elevators are counted as contributing to the means of egress capacity, the following shall apply:

(1) They shall account for no more than 50 percent of the required egress capacity.
(2)*At least one elevator shall be considered out of service, and one elevator shall be reserved for fire service.
(3)*The capacity of each elevator shall be the carrying capacity of the elevator within 30 minutes.

5.3.6.3 Holding Area. Elevators counted as contributing to the means of egress capacity from any level of a station shall be accessed via holding areas or lobbies at that level, which shall be designed as follows:

(1) The holding areas or lobbies shall be separated from the platform by a smoketight fire separation having a fire resistance rating of at least 1 hour but not less than the time required to evacuate the holding area occupant load.
(2) At least one stair shall be accessible from the holding area.
(3) The holding area shall be sized to accommodate one person per 0.46 m^2 (5 ft^2).
(4) If the holding area includes portions of the platform, the area within 460 mm (18 in.) of the trainway shall not be considered in the calculation.
(5) Upon activation of smoke control in the platform or adjacent trainway areas, the holding area shall be pressurized to a minimum of 25 Pa (0.1003 in. of water gauge).
(6) The holding area shall be provided with emergency voice alarm devices with two-way communication to the system operations control center.

5.3.6.4 Design Features. Elevators counted as contributing to the means of egress capacity shall be designed as follows:

(1) Shaft enclosures shall be constructed as fire separations having a 2-hour fire resistance rating.
(2)*The design shall limit water flow into the shaft.
(3) No more than two elevators used for means of egress or fire department access shall share the same machine room.
(4) Machine rooms shall be separated from each other by fire separations having a minimum fire resistance rating of 2 hours.
(5) The elevators shall be connected to emergency power.
(6)*During emergency evacuation, the elevators shall travel only between the incident level and a point of safety.
(7)*Provisions for Phase I emergency recall operation shall be based on analysis of fire scenarios on each level served and demonstrate safe egress for those scenarios.

5.3.7* Doors, Gates, and Exit Hatches.

5.3.7.1 The egress capacity for doors and gates in a means of egress serving public areas shall be computed as follows:

(1) 60 people per minute (p/min) for single leaf doors and gates
(2)*0.0819 p/mm-min (2.08 p/in.-min) for bi-parting multileaf doors and gates measured for the clear width dimension.

5.3.7.2 Gates in a means of egress shall be designed in accordance with the requirements for doors serving as a means of egress.

5.3.7.3 Where used, exit hatches shall comply with the requirements of 6.3.3.15 through 6.3.3.17.

5.3.8 Fare Barriers.

5.3.8.1 Fare barriers complying with 5.3.8.2 through 5.3.8.5 shall be permitted in the means of egress serving stations.

5.3.8.2* Except as permitted in 5.3.8.3, fare barriers in the required means of egress shall be designed to release, permitting unimpeded travel in the direction of egress under all the following conditions:

(1) Power failure or ground fault condition
(2) Activation of the station fire alarm signal
(3) Manual activation from a switch in a constantly attended location in the station or operations control center

5.3.8.3 Fare barriers that do not comply with the requirements of 5.3.8.2 shall be permitted in the means of egress where barriers in the equipment are designed to provide egress when a horizontal force not exceeding 66N (15lbf) is applied in the egress direction.

5.3.8.4 Gate-type fare barriers in the means of egress shall meet the following criteria:

(1)*Each unit shall provide a minimum of 455 mm (18 in.) clear width at and below a height of 1000 mm (39.5 in.) and 530 mm (21 in.) clear width above that height.
(2) Each unit shall be credited with a capacity of 50 p/min for egress calculations.

5.3.8.5 Turnstile-type fare barriers shall be permitted in accordance with NFPA *101* and shall in the means of egress shall meet the following criteria:

(1) Dimensions shall be in accordance with the requirements of NFPA *101.*
(2) Turnstiles that drop away from the egress opening under the conditions listed in 5.3.8.2 or 5.3.8.3 shall be credited with a capacity of 50 p/min for egress calculations.
(3) Turnstiles that revolve freely in the direction of egress under the conditions listed in 5.3.8.2 shall meet the following criteria:
    (a) Each unit shall be credited with a capacity of 25 p/min for egress calculations.
    (b) The turnstiles shall not account for more than 50 percent of the required egress capacity for each egress route.

5.3.8.6* Fare barriers shall be designed so that their failure to operate properly will not prohibit movement of passengers in the direction of emergency egress.

5.3.9 Horizontal Exits.

5.3.9.1* Horizontal exits compliant with NFPA *101* shall be permitted for up to 100 percent of the number of horizontal exits and required egress capacity provided that not more than 50 percent of the number and required capacity is into a single building.

5.3.10 Platform Screen and Edge Doors.

5.3.10.1 Horizontal sliding platform screen or platform edge doors shall be permitted to separate the platform from the trainway in stations, provided that the following criteria are met:

(1) The doors permit emergency egress from the train to the platform regardless of the stopping position of the train.
(2) The doors provide egress when a force not exceeding 220 N (50 lb) is applied from the train side of the doors.
(3) The doors are designed to withstand positive and negative pressures caused by passing trains.

5.3.11 Means of Egress Lighting.

5.3.11.1 Illumination of the means of egress in stations, including escalators that are considered a means of egress, shall be in accordance with Section 7.8 of NFPA *101.*

5.3.11.2 Means of egress, including escalators considered as means of egress, shall be provided with a system of emergency lighting in accordance with Section 7.9 of NFPA *101.*

5.3.11.3 In addition to the requirements of 5.3.11.1 and 5.3.11.2:

(1) Lighting for stairs and escalators shall be designed to emphasize illumination on the top and bottom steps and landings.
(2) Where newel- and comb-lighting is provided for escalator steps, such lighting shall be on emergency power circuits.

5.4 Fire Protection.

5.4.1* Fire Command Center.

5.4.1.1 Enclosed stations shall be provided with a fire command center in accordance with *NFPA 72.*

5.4.1.2 The ventilation systems at adjacent trainways and stations shall be permitted to be omitted from the controls of the fire command center.

5.4.2 Protective Signaling Systems.

5.4.2.1 Stations equipped with fire alarm devices shall be protected by a proprietary supervising station alarm system as defined in *NFPA 72.*

5.4.2.2* Each station having fire alarm initiating devices shall be provided with a fire alarm annunciator panel at a location that is accessible to emergency response personnel in accordance with *NFPA 72.*

5.4.2.3 The location of the fire alarm annunciator panel shall be approved.

5.4.2.4 Annunciator panels shall announce by audible alarm the activation of any fire alarm initiating device in the station and visually display the location of the actuated device.

5.4.2.5 When activated, all indicator signals for fire alarms, smoke detection, valve switches, and waterflow shall be transmitted simultaneously to the local station and to the operations control center.

5.4.2.6* Separate zones shall be established on local station annunciator panels to monitor waterflow on sprinkler systems and supervise main control valves.

5.4.2.7 Automatic fire detection shall be provided in all ancillary spaces by the installation of listed combination fixed-temperature and rate-of-rise heat detectors or listed smoke detectors except where protected by automatic sprinklers.

5.4.2.8 Fire alarm systems shall be inspected, tested, and maintained in accordance with *NFPA 72.*

5.4.3 Emergency Communication.

5.4.3.1 A public address (PA) system and emergency voice alarm reporting devices, such as emergency telephone boxes or manual fire alarm boxes conforming to *NFPA 72*, shall be required in stations.

5.4.3.2 The operations control center and each system station shall be equipped with an approved emergency voice/alarm communication system so that appropriate announcements can be made regarding fire alarms, including provisions for giving necessary information and directions to the public upon receipt of any manual or automatic fire alarm signal.

5.4.3.3 The notification devices shall be placed in approved locations at each facility.

5.4.3.4 Emergency alarm reporting devices shall be located on passenger platforms and throughout the stations such that the travel distance from any point in the public area shall not exceed 100 m (325 ft) unless otherwise approved.

5.4.3.5 Such emergency devices shall be distinctive in color, and their locations shall be plainly indicated by appropriate signs.

5.4.4 Automatic Fire Suppression Systems.

5.4.4.1* An automatic sprinkler protection system shall be provided in areas of stations used for concessions, in storage areas, in trash rooms, and other similar areas with combustible loadings, except trainways.

5.4.4.2 Sprinkler protection shall be permitted to be omitted in areas of open stations remotely located from public spaces.

5.4.4.3 Installation of sprinkler systems shall comply with NFPA 13 or applicable local codes as required.

5.4.4.4 A sprinkler system waterflow alarm and supervisory signal service shall be installed.

5.4.4.5 Other fire suppression systems, if approved, shall be permitted to be substituted for automatic sprinkler systems in the areas listed in 5.4.4.1.

5.4.4.6 Automatic fire sprinkler systems shall be tested and maintained in accordance with NFPA 25.

5.4.5 Standpipe and Hose Systems.

5.4.5.1* Class I standpipes shall be installed in enclosed stations in accordance with NFPA 14 except as modified herein.

5.4.5.2 Standpipe systems shall not be required to be enclosed in fire-rated construction provided the following conditions are met:

(1) The system is cross-connected or fed from two locations.
(2) Isolation valves are installed not more than 245 m (800 ft) apart.

5.4.5.3 In addition to the usual identification required on fire department connections for standpipes, there shall also be wording to identify the fire department connection as part of the station system.

5.4.5.4* Standpipes shall be permitted to be of the dry type with the approval of the authority having jurisdiction provided the following requirements are met:

(1)*Systems shall be installed in a manner so that the water is delivered to all hose connections on the system in 10 minutes or less.
(2) Combination air relief–vacuum valves shall be installed at each high point on the system.

5.4.5.5 Dry standpipes shall be permitted to be concealed without the piping integrity being monitored with a supervisory air pressure provided they are pressure tested annually.

5.4.5.6 Where enclosed stations include more than one platform level (such as crossover subway lines), there shall be a cross-connection pipe of a minimum size of 100 mm (4 in.) in diameter between each standpipe system, so that supplying water through any fire department connection will furnish water throughout the entire system.

5.4.5.7 Standpipe and hose systems shall be tested and maintained in accordance with NFPA 25.

5.4.6 Portable Fire Extinguishers. Portable fire extinguishers in such number, size, type, and location as determined by the authority having jurisdiction shall be provided.

5.4.6.1 Portable fire extinguishers shall be maintained in accordance with NFPA 10.

5.4.7 Ventilation.

5.4.7.1 Emergency ventilation shall be provided in enclosed stations in accordance with Chapter 7.

5.4.8 Emergency Power.

5.4.8.1 Emergency power in accordance with Article 700 of *NFPA 70,* and Chapter 4 of NFPA 110 shall be provided for enclosed stations.

5.4.8.2 The supply system for emergency purposes, in addition to the normal services to the station building, shall be one or more of the types of systems described in 700.12(A) through 700.12(E) of *NFPA 70*.

5.4.8.3 The emergency power system shall have a capacity and rating sufficient to supply all equipment required to be connected by 5.4.8.5.

5.4.8.4 Selective load pickup and load shedding shall be permitted in accordance with *NFPA 70*.

5.4.8.5 Systems connected to the emergency power system shall include the following:

(1) Emergency lighting
(2) Protective signaling systems
(3) Emergency communication system
(4) Fire command center
(5) Elevators providing required egress capacity [see 5.3.6.4(5)]

5.4.8.6 The emergency lighting and communications circuits shall be protected from physical damage by system vehicles or other normal system operations and from fire as described in 12.4.4.

Chapter 6 Trainways

6.1 General.

6.1.1* Applicability. This chapter applies to all portions of the trainway, including pocket storage and tail tracks not intended for occupancy by passengers.

6.1.2 Use and Occupancy.

6.1.2.1 Passengers shall enter the trainways only in the event that it becomes necessary to evacuate a train.

6.1.2.2 Evacuation shall take place only under the guidance and control of authorized, trained system employees or other authorized personnel as warranted under an emergency situation.

6.1.2.3* Warning signs in accordance with 6.3.5.1 shall be posted at locations where unauthorized personnel might trespass.

6.2 Construction.

6.2.1 Safeguards During Construction.

6.2.1.1 A standpipe system shall be installed in enclosed trainways under construction in accordance with NFPA 241.

6.2.1.2 The standpipe system shall be installed before the enclosed trainway has exceeded a length of 61 m (200 ft) beyond any access shaft or portal and shall be extended as work progresses to within 61 m (200 ft) of the most remote portion of the enclosed trainway.

6.2.1.3 Standpipes shall be sized for approved water flow and pressure at the outlet, based upon the maximum predicted fire load.

6.2.1.4 Reducers or adapters shall meet the following criteria:

(1) Be provided and attached for connection to the contractor's hose
(2) Be readily removable through the use of a fire fighter's hose spanner wrench

6.2.1.5 Risers shall meet the following criteria:

(1) Be identified with signs as outlined in 6.4.4.7
(2) Be readily accessible for fire department use
(3) Be protected from accidental damage

6.2.1.6* Illumination levels in enclosed trainways under construction shall not be less than 2.7 lx (0.25 ft-candles) at the walking surface.

6.2.2 Construction Type.

6.2.2.1* Cut and Cover. Where trainway sections are to be constructed by the cut-and-cover method, perimeter walls and related construction shall be not less than Type I or Type II or combinations of Type I or Type II noncombustible construction as defined in NFPA 220, as determined by an engineering analysis of potential fire exposure hazards to the structure.

6.2.2.2 Bored Tunnels. Where trainway sections are to be constructed by a tunneling method through earth, unprotected steel liners, reinforced concrete, shotcrete, or equivalent shall be used.

6.2.2.3 Rock Tunnels. Rock tunnels shall be permitted to utilize steel bents with concrete liner if lining is required.

6.2.2.4 Underwater Tubes. Underwater tubes shall be not less than Type II (000) noncombustible construction as defined in NFPA 220, as applicable.

6.2.2.5 Exit and Ventilation Structures. Remote vertical exit shafts and ventilation structures shall be not less than Type I (332) noncombustible construction as defined in NFPA 220.

6.2.2.6 Surface. Construction materials shall be not less than Type II (000) noncombustible material as defined in NFPA 220, as determined by a fire hazard analysis of potential fire exposure hazards to the structure.

6.2.2.7 Elevated. All structures necessary for trainway support and all structures and enclosures on or under trainways shall be of not less than Type I or Type II (000) or combinations of Type I or Type II noncombustible construction as defined in NFPA 220, as determined by a fire hazard analysis of potential fire exposure hazards to the structure.

6.2.3 Flammable and Combustible Liquids Intrusion.

6.2.3.1 General. Protection of underground system structures against the accidental intrusion of flammable and combustible liquids shall meet the requirements of 5.2.3.

6.2.4* Compartmentation.

6.2.4.1 Ancillary areas shall be separated from trainway areas within underwater trainway sections by construction having a minimum 3-hour fire-resistance rating.

6.2.4.2 Ancillary areas shall be separated from trainway areas within enclosed trainway sections by construction having a minimum 2-hour fire-resistance rating.

6.2.5 Combustible Components.

6.2.5.1 Where combustible components not specifically addressed in this standard are installed in a trainway, a fire hazard analysis shall be conducted to determine that the level of occupant fire safety is not adversely affected by the contents.

6.2.5.2 The fire hazard analysis required by 6.2.5.1 shall meet the following criteria:

(1) It shall include, as a minimum, an examination of peak heat release rate for combustible elements, total heat released, ignition temperatures, radiant heating view factors, and behavior of the component during internal or external fire scenarios.
(2) It shall determine that, if a fire propagates beyond involving the component of fire origin, a level of fire safety is provided within an enclosed trainway commensurate with this standard.

6.2.5.3 Computer modeling, material fire testing, or full-scale fire testing shall be conducted to assess performance in potential fire scenarios.

6.2.6 Walking Surfaces.

6.2.6.1 Walking surfaces designated for evacuation of passengers shall be constructed of noncombustible materials.

6.2.7 Coverboard or Protective Material.

6.2.7.1 Coverboard or protective material shall have a flame spread index of not more than 25 and a smoke developed index not exceeding 450 when tested in accordance with ASTM E 84.

6.2.7.2 Coverboard protective material tested in accordance with NFPA 286 shall comply with the following:

(1) Flames shall not spread to the ceiling during the 40 kW (135 kBtu/hr) exposure.
(2) Flames shall not spread to the outer extremities of the sample on any test room wall or ceiling.
(3) Flashover as described in NFPA 286 shall not occur.
(4) The peak heat release rate throughout the test shall not exceed 800 kW (2730 kBtu/hr).
(5) The total smoke released throughout the test shall not exceed 1000 m^2 (10,764 ft^2).

6.2.8 Rail Ties.

6.2.8.1 Rail ties used in enclosed locations shall be noncombustible materials.

6.2.8.2 Rail ties used at switch or crossover locations shall comply with 6.2.8.1 or shall be fire–retardant treated wood in accordance with NFPA 703.

6.2.8.3 Rail ties and tie blocks in enclosed track sections shall be permitted to be of wood encased in concrete such that only the top surface is exposed.

6.3 Emergency Egress.

6.3.1 Location of Egress Routes.

6.3.1.1* The system shall incorporate a walk surface or other approved means for passengers to evacuate a train at any point along the trainway so that they can proceed to the nearest station or other point of safety.

6.3.1.2 Walkway continuity shall be maintained at special track sections (e.g., crossovers, pocket tracks).

6.3.1.3 Walkway continuity shall be provided by crosswalks at track level.

6.3.1.4* Within enclosed trainways, the maximum distance between exits shall not exceed 762 m (2500 ft).

6.3.1.5 Cross-passageways shall be permitted to be used in lieu of emergency exit stairways to the surface where trainways in tunnels are divided by a minimum of 2 hour–rated fire separations or where trainways are in twin bores.

6.3.1.6 Where cross-passageways are utilized in lieu of emergency exit stairways, the following requirements shall apply:

(1) Cross-passageways shall not be farther than 244 m (800 ft) apart.
(2)*Cross-passageways shall not be farther than 244 m (800 ft) from the station or portal of the enclosed trainway.
(3) Cross-passageways shall be separated from the trainway with self-closing fire door assemblies having a fire protection rating of 1½ hours.
(4) A tenable environment shall be maintained in the portion of the trainway that is not involved in an emergency and that is being used for evacuation.
(5) A ventilation system for the incident trainway shall be designed to control smoke in the vicinity of the passengers.
(6) Provisions shall be made for evacuating passengers via the non-incident trainway to a nearby station or other emergency exit.
(7)*The provisions shall include measures to protect passengers from oncoming traffic and from other hazards.

6.3.1.7 Where cross-passageways are used in lieu of emergency exit stairways, the interior of the cross-passage shall not be used for any purpose other than as an area of refuge or for access/egress to the opposite tunnel except under the following conditions:

(1) The use of cross-passages for the installation of noncombustible equipment is permitted.
(2) Installed equipment does not intrude into the required clear width of the cross-passage.

6.3.1.8 In areas where cross-passageways are provided, walkways shall be provided on the cross-passageway side of the trainway for unobstructed access to the cross-passageway.

6.3.1.9 For open-cut trainways, an engineering analysis shall be conducted to evaluate the impact of the trainway configuration on safe egress from a train fire to a point of safety.

6.3.1.10 Where the engineering analysis indicates that the configuration will impact tenability beyond the immediate vicinity of the fire, egress routes shall be provided such that the maximum distance from any point within the open-cut section to a point of egress from the trainway shall not be more than 381 m (1250 ft).

6.3.2 Size of Egress Routes

6.3.2.1* The means of egress within the trainway shall be provided with an unobstructed clear width graduating from 610 mm (24 in.) at the walking surface to 760 mm (30 in.) at 1575 mm (62 in.) above the walking surface to 430 mm (17 in.) at 2025 mm (80 in.) above the walking surface.

6.3.2.2 Cross-passageways shall be a minimum of 1120 mm (44 in.) in clear width and 2100 mm (7 ft) in height.

6.3.2.3* The width of exit stairs shall not be required to exceed 1120 mm (44 in.) for enclosed trainways.

6.3.2.4* Doors in egress routes serving trainways shall have a minimum clear width of 810 mm (32 in.).

6.3.3* Egress Components.

6.3.3.1 Walking surfaces serving as egress routes within guideways shall have a uniform, slip-resistant design.

6.3.3.2 Guideway crosswalks shall have a uniform walking surface at the top of the rail.

6.3.3.3 Where the trainway track bed serves as the emergency egress pathway, it shall be nominally level and free of obstructions.

6.3.3.4 Except as permitted in 6.3.3.3, walking surfaces shall have a uniform, slip-resistant design.

6.3.3.5* Walkways that are more than 760 mm (30 in.) above the floor or grade below shall be provided with a continuous guard to prevent falls over the open side.

6.3.3.6 Guards shall not be required along the trainway side of raised walkways where the bottom of the trainway is closed by a deck or grating.

6.3.3.7 Guards shall not be required on raised walkways that are located between two trainways.

6.3.3.8* Walkways that are more than 760 mm (30 in.) above the floor or grade below shall be provided with a continuous handrail along the side opposite the trainway.

6.3.3.9 Raised walkways that are greater than 1120 mm (44 in.) wide and located between two trainways shall not be required to have a handrail.

6.3.3.10 Exit stairs and doors shall comply with Chapter 7 of NFPA *101*, except as herein modified.

6.3.3.11 Doors in the means of egress, except cross-passageway doors, shall open in the direction of exit travel.

6.3.3.12 Doors in the means of egress shall comply with the following:

(1) Open fully when a force not exceeding 220 N (50 lb) is applied to the latch side of the door
(2) Be adequate to withstand positive and negative pressures caused by passing trains and the emergency ventilation system

6.3.3.13 Horizontal sliding doors shall be permitted in cross-passageways.

6.3.3.14 Platform end gates shall meet the clear width requirements for gate-type fare barriers. *(See Chapter 5.)*

6.3.3.15 Exit hatches shall be permitted in the means of egress, provided the following conditions are met:

(1) Hatches shall be equipped with a manual opening device that can be readily opened from the egress side.
(2) Hatches shall be operable with not more than one releasing operation.
(3) The force required to open the hatch when applied at the opening device shall not exceed 130 N (30 lb).
(4) The hatch shall be equipped with a hold-open device that automatically latches the door in the open position to prevent accidental closure.

6.3.3.16 Exit hatches shall be capable of being opened from the discharge side to permit access by authorized personnel.

6.3.3.17* Exit hatches shall be conspicuously marked on the discharge side to prevent possible blockage.

6.3.4 Traction Power Protection.

6.3.4.1* This subsection shall apply to the traction power subsystem installed in all trainways, which shall include the wayside pothead, the cable between the pothead and the contact (third) rail or overhead contact system (OCS), the contact rail or OCS supports, and special warning and identification devices, as well as electrical appurtenances associated with overhead contact systems.

6.3.4.2 To provide safety isolation from the contact rail, the following requirements shall apply:

(1) Power rail conductor(s) (dc or ac, which supply power to the vehicle for propulsion and other loads) shall be secured to insulating supports, bonded at joints, and protected to prevent contact with personnel.
(2) The design shall include measures to prevent inadvertent contact with the live power rails where such power rails are adjacent to emergency or service walkways and where walkways cross over trainways.
(3) Coverboards, where used, shall be capable of supporting a vertical load of 1125 N (250 lb) at any point with no visible permanent deflection.

6.3.4.3 To provide isolation from the overhead contact system, the following requirements shall apply:

(1) Power conductor(s) (dc or ac, which supply power to the vehicle for propulsion and other loads) shall be secured to insulating supports, bonded at joints, and protected to prevent contact with personnel.
(2) Insulating material for the cable connecting power to the power rail or OCS shall meet the FT4/IEEE 1202 exposure requirements for cable char height, total smoke released, and peak smoke release rate of ANSI/UL 1685.

6.3.5 Signage, Illumination, and Emergency Lighting.

6.3.5.1 Warning signs posted on entrances to the trainway and on fences or barriers adjacent to the trainway shall clearly state the hazard (e.g., DANGER HIGH VOLTAGE — 750 VOLTS) with letter sizes and colors in conformance with *NFPA 70* and Occupational Safety and Health Administration (OSHA) requirements.

6.3.5.2 System egress points shall be illuminated.

6.3.5.3 Points of exit from elevated and enclosed trainways shall be marked with internally or externally illuminated signs.

6.3.5.4 Identification. Emergency exit facilities shall be identified and maintained to allow for their intended use.

6.3.5.5 Enclosed trainways greater in length than the minimum length of one train shall be provided with directional signs as appropriate for the emergency procedures developed for the fixed guideway transit or passenger rail system in accordance with Chapter 9.

6.3.5.6 Directional signs indicating station or portal directions shall be installed at maximum 25 m (82 ft) intervals on either side of the enclosed trainways.

6.3.5.7 Directional signs shall be readily visible by passengers for emergency evacuation.

6.3.5.8 The requirements of 6.3.5.9 through 6.3.5.14 shall apply to all enclosed trainways that are greater than 30.5 m (100 ft) in length or two car lengths, whichever is greater.

6.3.5.9* Lighting systems shall be designed so that, during a period of evacuation, illumination levels of trainway walkways and walking surfaces shall not be less than 2.7 lx (0.25 ft-candles), measured along the path of egress at the walking surface.

6.3.5.10 The emergency lighting system in the trainway shall produce illumination on the walkway that does not exceed a uniformity ratio of 10:1 for the maximum maintained horizontal illuminance to the minimum maintained horizontal illuminance.

6.3.5.11* Point illumination of means of egress elements shall be permitted to exceed the 10:1 uniformity ratio.

6.3.5.12 Lighting systems for enclosed trainways shall be installed in accordance with Sections 7.8 and 7.9 of NFPA *101*, except as otherwise noted in 6.3.5.

6.3.5.13 Exit lights, essential signs, and emergency lights shall be included in the emergency lighting system in accordance with *NFPA 70*.

6.3.5.14 Emergency fixtures, exit lights, and signs shall be wired separately from emergency distribution panels.

6.4 Fire Protection and Life Safety Systems.

6.4.1 Emergency Access.

6.4.1.1 Except as described herein, points of egress and exits from the guideway shall serve as emergency access routes.

6.4.1.2 If security fences are used along the trainway, access gates shall be provided in security fences, as deemed necessary by the authority having jurisdiction.

6.4.1.3 Access gates shall be a minimum 1120 mm (44 in.) wide and shall be of the hinged or sliding type.

6.4.1.4 Access gates shall be placed as close as practicable to the portals to permit easy access to tunnels.

6.4.1.5 Information that clearly identifies the route and location of each gate shall be provided on the gates or adjacent thereto.

6.4.1.6 Access to the elevated trainway shall be from stations or by mobile ladder equipment from roadways adjacent to the trackway.

6.4.1.7 If no adjacent or crossing roadways exist for the elevated trainway, access roads at a maximum of 762 m (2500 ft) intervals shall be required.

6.4.1.8 Where the configuration of an open-cut trainway prevents or impedes access for firefighting, provisions shall be made to permit fire fighter access to that section of trainway at intervals not exceeding 762 m (2500 ft).

6.4.2 Blue Light Stations.

6.4.2.1* Blue light stations shall be provided at the following locations:

(1) At the ends of station platforms
(2) At cross-passageways
(3) At emergency access points
(4) At traction power substations
(5) In enclosed trainways as approved

6.4.2.2 Adjacent to each blue light station, information shall be provided that identifies the location of that station and the distance to an exit in each direction.

6.4.2.3 For blue light stations at elevated guideways, the graphics shall be legible from the ground level outside the trackway.

6.4.2.4 In systems with overhead traction power, the requirement to disconnect traction power shall be permitted by an approved alternative means.

6.4.3 Automatic Fire Detection.

6.4.3.1 Heat and smoke detectors shall be installed at traction power substations and signal bungalows and shall be connected to the operations control center.

6.4.3.2 Signals received from such devices shall be identifiable as to the origin of the signals.

6.4.4 Standpipe and Hose Systems.

6.4.4.1 An approved fire standpipe system shall be provided in enclosed trainways where physical factors prevent or impede access to the water supply or fire apparatus, where required by the authority having jurisdiction.

6.4.4.2* Class I standpipe systems shall be installed in trainways in accordance with NFPA 14 except as modified herein.

6.4.4.3 Standpipe systems shall not be required to be enclosed in fire-rated construction, provided the following conditions are met:

(1) The system is cross-connected or fed from two locations.
(2) Isolation valves are installed not more than 244 m (800 ft) apart.

6.4.4.4 Standpipes shall be permitted to be of the dry type with the approval of the authority having jurisdiction provided the following conditions are met:

(1)*Standpipes shall be installed so that the water is delivered to all hose connections on that standpipe in 10 minutes or less.
(2) Combination air relief–vacuum valves shall be installed at each high point on the standpipe.

6.4.4.5 Standpipe systems shall be provided with an approved water supply capable of supplying the system demand for a minimum of 1 hour.

6.4.4.6 Acceptable water supplies shall include the following:

(1) Municipal or privately owned waterworks systems that have adequate pressure, flow rate, and level of integrity
(2) Automatic or manually controlled fire pumps that are connected to water source
(3) Pressure-type or gravity-type storage tanks that are installed in accordance with NFPA 22

6.4.4.7 Identification numbers and letters conforming to the system sectional identification numbers and letters shall be provided at each surface fire department connection and at each hose valve on the standpipe lines.

6.4.4.8 Identifying signs shall be affixed to enclosed trainway walls at each hose outlet valve or shall be painted directly on the standpipe in white letters next to each hose outlet valve.

6.4.4.9 Exposed standpipe lines and identification signs shall be painted as required by the authority having jurisdiction.

6.4.4.10 A fire department access road shall extend to within 30.5 m (100 ft) of the fire department connection.

6.4.5 Portable Fire Extinguishers.

6.4.5.1 Portable fire extinguishers shall be provided in such numbers, sizes, and types and at such locations in enclosed trainways as determined by the authority having jurisdiction.

6.4.6 Ventilation.

6.4.6.1 Except as described in 6.4.6.2 and 6.4.6.3, emergency ventilation shall be provided in enclosed trainways in accordance with Chapter 7.

6.4.6.2* Emergency ventilation meeting the tenability criteria for occupied spaces shall not be required in tail track areas where engineering analysis indicates that a fire on a train in the tail track area will not impact passengers or passenger areas.

6.4.6.3* Emergency ventilation meeting the tenability criteria for occupied areas shall not be required in storage track areas where the storage track has no openings along its length to passenger trainway areas and where an engineering analysis indicates that a fire on a train in the storage track area will not impact passengers or passenger areas.

6.4.7 Emergency Power.

6.4.7.1 Enclosed trainways shall be such that, in the event of failure of the normal supply to or within the system, emergency power shall be provided in accordance with Article 700 of *NFPA 70* and Chapter 4 of NFPA 110. The supply system for emergency purposes, in addition to the normal services to the trainway, shall be one or more of the types of systems described in 700.12(A) through 700.12(E) of *NFPA 70*.

6.4.7.2 The following systems shall be connected to the emergency power system:

(1) Emergency lighting
(2) Protective signaling systems
(3) Emergency communication system
(4) Fire command center

6.4.7.3 The emergency lighting and communications circuits shall be protected from physical damage by system vehicles or other normal system operations and from fire as described in 12.4.4.

•

Chapter 7 Emergency Ventilation System

7.1 General.

7.1.1* This chapter defines the requirements for the environmental conditions and the mechanical and nonmechanical ventilation systems used to meet those requirements for a fire emergency in a system station, trainway, or both as required by 5.3.3 and 6.3.2.

7.1.2 The requirement for a mechanical or nonmechanical system intended for the purpose of emergency ventilation shall be determined in accordance with 7.1.2.1 through 7.1.2.4.

7.1.2.1 For length determination, all contiguous enclosed trainway and underground system station segments between portals shall be included.

7.1.2.2* A mechanical emergency ventilation system shall be provided in the following locations:

(1) In an enclosed system station
(2) In a system underground or enclosed trainway that is greater in length than 1000 ft (305 m)

7.1.2.3 A mechanical emergency ventilation system shall not be required in the following locations:

(1) In an open system station
(2) Where the length of an underground trainway is less than or equal to 200 ft (61 m)

7.1.2.4 Where supported by engineering analysis, a nonmechanical emergency ventilation system shall be permitted to be provided in lieu of a mechanical emergency ventilation system in the following locations:

(1) Where the length of the underground or enclosed trainway is less than or equal to 1000 ft (305 m) and greater than 200 ft (61 m)
(2) In an enclosed station where engineering analysis indicates that a nonmechanical emergency ventilation system supports the tenability criteria of the project

7.1.2.5 In the event that an engineering analysis is not conducted or does not support the use of a nonmechanical emergency ventilation system for the configurations described in 7.1.2.4, a mechanical emergency ventilation system shall be provided.

7.1.3 The engineering analysis of the ventilation system shall include a validated subway analytical simulation program augmented as appropriate by a quantitative analysis of airflow dynamics produced in the fire scenario, such as would result from the application of validated computational fluid dynamics (CFD) techniques. The results of the analysis shall include the no-fire (or cold) air velocities that can be measured during commissioning to confirm that a mechanical ventilation system as built meets the requirements determined by the analysis.

7.1.4 Where required by 7.1.2, the mechanical emergency ventilation system shall make provisions for the protection of passengers, employees, and emergency personnel from fire and smoke during a fire emergency.

7.2 Design.

7.2.1 The emergency ventilation system shall be designed to do the following:

(1) Provide a tenable environment along the path of egress from a fire incident in enclosed stations and enclosed trainways
(2) Produce sufficient airflow rates within enclosed trainways to meet critical velocity
(3)*Be capable of reaching full operational mode within 180 seconds
(4) Accommodate the maximum number of trains that could be between ventilation shafts during an emergency
(5) Maintain the required airflow rates for a minimum of 1 hour but not less than the required time of tenability

7.2.1.1 Where the airflow rates required to accomplish 7.2.1(1), 7.2.1(2), or approved alternative performance criteria are dependent upon the unimpaired function of the air distribution system, that system shall be designed to continue operation when exposed to the conditions generated during the design incident for the duration determined as per 7.2.1(5). Although rating is not required, materials or systems that are fire rated for the required duration shall be permitted to be used.

7.2.2 Point-extract ventilation systems shall be permitted subject to an engineering analysis that demonstrates the system will confine the spread of smoke in the tunnel to a length of 150 m (500 ft) or less.

7.2.3 The design shall encompass the following:

(1) The fire heat release rate and fire smoke release rate produced by the combustible load of a vehicle and any combustible materials that could contribute to the fire load at the incident site
(2) The fire growth rate
(3) Station and trainway geometries
(4) The effects of elevation, elevation differences, ambient temperature differences, and ambient wind
(5) A system of fans, shafts, and devices for directing airflow in stations and trainways
(6) A program of predetermined emergency response procedures capable of initiating prompt response from the operations control center in the event of a fire emergency
(7) A ventilation system reliability analysis that, as a minimum, considers the following subsystems:
    (a) Electrical
    (b) Mechanical
    (c) Supervisory control

7.2.4 Criteria for the system reliability analysis in 7.2.3(7) shall be established and approved.

7.2.4.1 The analysis shall consider as a minimum the following events:

(1) Fire in trainway or station
(2) Local incident within the electrical utility that interrupts power to the emergency ventilation system
(3) Derailment

7.2.5* The design and operation of the signaling system, traction power blocks, and ventilation system shall be coordinated to match the total number of trains that could be between ventilation shafts during an emergency.

7.2.6* The time-of-tenability criteria for stations and trainways shall be established and approved. For stations, the time shall be greater than the calculated egress time used to establish egress capacity in 5.3.2.1.

7.2.7 Ventilation air distribution systems shall be permitted to serve more than one trainway.

7.3 Emergency Ventilation Fans.

7.3.1 The ventilation system fans that are designated for use in fire and similar emergencies shall be capable of satisfying the emergency ventilation requirements to move trainway air in either direction as required to provide the needed ventilation response.

7.3.1.1 Individual emergency ventilation fan motors shall be designed to achieve their full operating speed in no more than

30 seconds from a stopped position when started across the line and in no more than 60 seconds for variable-speed motors.

7.3.1.2 The ventilation system designated for use in emergencies shall be capable of operating at full capacity in either the supply mode or exhaust mode to provide the needed ventilation response where dilution of noxious products is to be maximized.

7.3.1.3 The ventilation system designated for use in emergencies shall be capable of being turned off and dampers closed to provide the needed ventilation response where dispersion of noxious products is to be minimized.

7.3.2 Emergency ventilation fans, their motors, and all related components exposed to the exhaust airflow shall be designed to operate at the fan inlet airflow hot temperature condition from the design fan for a minimum of 1 hour.

7.3.2.1 The fan inlet airflow hot temperature shall be determined by an engineering analysis, however, this temperature shall not be less than 150°C (302°F).

7.3.2.2 The fan inlet airflow hot temperature shall be determined using the design fire at a location in the immediate vicinity of the emergency ventilation system track/station inlet(s), as applicable. Airflow rates shall be based upon the tunnel ventilation critical velocity or station tenability requirements, as applicable. These airflow rates will most likely be from location(s) that are different then the location for this hot temperature analysis.

7.3.2.3 Dampers that serve more than one trainway from a common duct system shall not be required to have a fire rating.

7.3.3 Fans shall be rated in accordance with the ANSI/AMCA 210, AMCA 300, AMCA 250, ASHRAE *Handbook — Fundamentals*, and ASHRAE 149.

7.3.4 Local fan motor starters and related operating control devices shall be located away from the direct airstream of the fans to the greatest extent practical.

7.3.4.1 Thermal overload protective devices in motors or on motor controls of fans used for emergency ventilation shall not be permitted.

7.3.5 Fans that are associated only with passenger or employee comfort and that are not designed to function as a part of the emergency ventilation system shall shut down automatically on identification and initiation of a fire emergency ventilation program so as not to jeopardize or conflict with emergency airflows.

7.3.5.1 Nonemergency ventilation airflows that do not impact the emergency ventilation airflows shall be permitted to be left operational where identified in the engineering analysis.

7.3.6 Critical fans required in battery rooms or similar spaces where hydrogen gases or other hazardous gases might be released shall be designed to meet the ventilation requirements of NFPA 91.

7.3.6.1 These fans and other critical fans in automatic train control rooms, communications rooms, and so forth, shall be identified in the engineering analysis and shall remain operational as required during the fire emergency.

7.4 Airflow Control Devices.

7.4.1 Devices that are interrelated with the emergency ventilation system and that are required to meet the emergency ventilation system airflows shall be structurally capable of withstanding both maximum repetitive and additive piston pressures of moving trains and emergency airflow velocities.

7.4.2 Devices in the emergency ventilation system that are exposed to the exhaust airflow and are critical to the system's effective functioning in the event of an emergency shall be constructed of materials suitable for operation in an ambient atmosphere at the design condition determined in 7.3.2.

7.4.2.1 Finishes applied to noncombustible devices shall not be required to meet the provisions of 7.4.2.

7.4.3 Other devices shall be designed to operate throughout the anticipated temperature range. Overcurrent elements in devices or on device controls required to support the emergency ventilation shall not be permitted where such overcurrent elements are subject to false operation due to exposure to elevated temperatures during a fire emergency.

7.5 Testing.

7.5.1* Equipment used for emergency ventilation (including fans, dampers, and airflow control devices) shall be listed for the application or shall be approved by the AHJ in accordance with the requirements of a recognized standard for the type of equipment to be installed.

7.5.2* The no-fire (or cold) airflows provided by the installed mechanical ventilation system shall be measured during commissioning to confirm that the airflows meet the requirements determined by the analysis.

7.6 Shafts.

7.6.1 Shafts that penetrate the surface and that are used for intake and discharge in fire or smoke emergencies shall be positioned or protected to prevent recirculation of smoke into the system through surface openings.

7.6.2 If the configuration required by 7.5.1 is not possible, surface openings shall be protected by other means to prevent smoke from re-entering the system.

7.6.3 Adjacent structures and property uses also shall be considered.

7.7 Emergency Ventilation System.

7.7.1 Operation of the emergency ventilation system components shall be initiated from the operations control center.

7.7.1.1 The operations control center shall receive verification of proper response by emergency ventilation fan(s) and an interrelated device(s).

7.7.1.2 Local controls shall be permitted to override the operations control center in all modes in the event the operations control center becomes inoperative or where the operation of the emergency ventilation system components is specifically redirected to another site.

7.7.2 For electrical substations and distribution rooms serving emergency ventilation systems where the local environmental conditions require the use of mechanical ventilation or cooling to maintain the space temperature below the electrical equipment operating limits, such mechanical ventilation or cooling systems shall be designed so that failure of any single air moving or cooling unit does not result in the loss of the electrical supply to the emergency ventilation fans during the specified period of operation.

7.8 Power Supply for Emergency Ventilation Systems.

7.8.1 The design of the power for the emergency ventilation system shall comply with the requirements of Article 700 of *NFPA 70*.

7.8.1.1 Alternatively, the design of the power for the emergency ventilation system shall be permitted to be based upon the results of the electrical reliability analysis according to 7.2.3(7), as approved.

7.8.1.2 The emergency ventilation circuits routed through the station public areas and trainway shall be protected from physical damage by fixed guideway transit or passenger rail vehicles or other normal operations and from fire as described in 12.4.4.

7.8.2 Overcurrent elements that are designed to protect conductors serving motors for both emergency fans and related emergency devices shall not be permitted where such overcurrent elements are subject to false operation due to exposure to elevated temperatures during a fire emergency. All other motor and fan protection devices shall be bypassed during a fire emergency, except for motor overcurrent and excessive vibration.

7.8.3 For electrical substations and distribution rooms serving emergency ventilation systems where the local environmental conditions require the use of mechanical ventilation or cooling to maintain the space temperature below the electrical equipment operating limits, such mechanical ventilation or cooling systems shall be designed so that failure of any single air-moving or air-cooling unit does not result in the loss of the electrical supply to the tunnel ventilation fans during the specified period of operation.

Chapter 8 Vehicles

8.1 Applicability.

8.1.1 New Vehicles. All new passenger-carrying vehicles shall be, at a minimum, designed and constructed to conform to the requirements set forth in this chapter.

8.1.2 Retrofit. Where existing passenger-carrying vehicles are to be retrofitted, the appropriate sections of this standard shall apply only to the extent of such retrofit.

8.2* Compliance Options. Passenger-carrying vehicles shall be designed to meet the prescriptive requirements of Section 8.3 through Section 8.10 or the engineering analysis requirements of Section 8.11.

8.3 Equipment Arrangement.

8.3.1 Equipment posing an ignition threat in vehicles, including associated electrical services, shall be isolated from the combustible materials in the passenger and crew compartments.

8.3.2* Equipment other than comfort heating equipment operating on voltage of greater than 300 V shall be located external to or isolated from passenger and crew compartments to prevent electrical failures from extending into those areas.

8.3.2.1 Vehicles powered by overhead contact shall be designed to prevent arc penetration, ignition, and fire spread growth of the roof assembly.

8.3.3 Methods used to isolate ignition sources from combustible materials shall be demonstrated to the AHJ to be suitable through testing and/or analysis.

8.3.4 Fuel tanks shall be designed to minimize passenger and crew exposure to fuel hazards.

8.4 Flammability and Smoke Emission.

8.4.1* The test procedures and minimum performance for materials and assemblies shall be as detailed in Table 8.4.1.

8.4.1.1* Materials tested for surface flammability shall not exhibit any flaming running or flaming dripping.

8.4.1.2 The ASTM E 662 maximum test limits for smoke emission (specific optical density) shall be based on both the flaming and the nonflaming modes.

8.4.1.3* Testing of a complete seat assembly (including cushions, fabric layers, and upholstery) according to ASTM E 1537 using the pass/fail criteria of California Technical Bulletin 133 and testing of a complete mattress assembly (including foam and ticking) according to ASTM E 1590 using the pass/fail criteria of California Technical Bulletin 129 shall be permitted in lieu of the test methods prescribed herein, provided the assembly component units remain unchanged or new (replacement) assembly components possess fire performance properties equivalent to those of the original components tested.

8.4.1.3.1 A fire hazard analysis shall also be conducted that considers the operating environment within which the seat or mattress assembly will be used in relation to the risk of vandalism, puncture, cutting, introduction of additional combustibles, or other acts that potentially expose the individual components of the assemblies to an ignition source.

8.4.1.3.2 The requirements of 8.4.1.5 through 8.4.1.8 shall be met.

8.4.1.4 Testing shall be performed without upholstery.

8.4.1.5 The surface flammability and smoke emission characteristics shall be demonstrated to be permanent after dynamic testing according to ASTM D 3574, Test I_2 or Test I_3, both using Procedure B, except that the test samples shall be a minimum of 150 mm (6 in.) × 450 mm (18 in.) × the thickness used in end-use configuration, or multiples thereof. If Test I_3 is used, the size of the indentor described in Section 96.2 of ASTM D 3574 shall be modified to accommodate the specified test specimen.

8.4.1.6 The surface flammability and smoke emission characteristics shall be demonstrated to be permanent by washing, if appropriate, in accordance with the manufacturer's recommended procedure. If a washing procedure is not provided by the manufacturer, the fabric shall be washed in accordance with ASTM E 2061, Annex A1.

8.4.1.7 The surface flammability and smoke emission characteristics shall be demonstrated to be permanent by dry cleaning, if appropriate, according to ASTM D 2724.

8.4.1.8 Materials that cannot be washed or dry-cleaned shall be so labeled and shall meet the applicable performance criteria after being cleaned as recommended by the manufacturer.

8.4.1.9 Combustible operational and safety signage shall not be required to meet flame spread or smoke emission requirements if the combustible mass of a single sign does not exceed 500 g (1.1 lb) and the aggregate area of combustible signage does not exceed 1 ft^2 per foot of car length.

Table 8.4.1 Fire Test Procedures and Performance Criteria for Materials and Assemblies

Category	Function of Material	Test Method	Performance Criteria
Cushioning	All individual flexible cushioning materials used in seat cushions, mattresses, mattress pads, armrests, crash pads, and grab rail padding [a–e]	ASTM D 3675	$I_s \leq 25$
		ASTM E 662	D_s (1.5) ≤ 100 D_s (4.0) ≤ 175
Fabrics	Seat upholstery, mattress ticking and covers, curtains, draperies, window shades, and woven seat cushion suspensions[a–c, f–h]	14 CFR 25, Appendix F, Part I (vertical test)	Flame time ≤ 10 sec Burn length ≤ 6 in.
		ASTM E 662	D_s (4.0) ≤ 200
Other vehicle components	Seat and mattress frames, wall and ceiling lining and panels, seat and toilet shrouds, toilet seats, trays and other tables, partitions, shelves, opaque windscreens, combustible signage, end caps, roof housings, articulation bellows, exterior shells, nonmetallic skirts, and component boxes and covers[a,b,i–k]	ASTM E 162	$I_s \leq 35$
		ASTM E 662	D_s (1.5) ≤ 100 D_s (4.0) ≤ 200
	Thermal and acoustical insulation[a,b]	ASTM E 162	$I_s \leq 25$
		ASTM E 662	D_s (4.0) ≤ 100
	HVAC ducting[a,b]	ASTM E 162	$I_s \leq 25$
		ASTM E 662	D_s (4.0) ≤ 100
	Floor covering[b,k,l]	ASTM E 648	CRF ≥ 5 kW/m^2
		ASTM E 662	D_s (1.5) ≤ 100 D_s (4.0) ≤ 200
	Light diffusers, windows, and transparent plastic windscreens[b,i]	ASTM E 162	$I_s \leq 100$
		ASTM E 662	D_s (1.5) ≤ 100 D_s (4.0) ≤ 200
	Adhesives and sealants	ASTM E 162	$I_s \leq 35$
		ASTM E 662	D_s (1.5) ≤ and D_s (4.0) ≤ 200
Elastomers[a,b,i,j]	Window gaskets, door nosings, intercar diaphragms, seat cushion suspension diaphragms, and roof mats	ASTM C 1166	Flame propagation ≤ 100 mm (4 in.)
		ASTM E 662	D_s (1.5) ≤ 100 D_s (4.0) ≤ 200
Wire and cable	All	See 8.6.7.1.1.1 through 8.6.7.1.3.	See 8.6.7.1.1.1 through 8.6.7.1.3.
Structural components[m]	Flooring,[n] other[o]	ASTM E 119	Pass

[b]See 8.4.1.2.
[c]See 8.4.1.3.
[d]See 8.4.1.4.
[e]See 8.4.1.5.
[f]See 8.4.1.6.
[g]See 8.4.1.7.
[h]See 8.4.1.8.
[i]See 8.4.1.9.
[j]See 8.4.1.10.
[k]See 8.4.1.11.
[l]See 8.4.1.12.
[m]See 8.4.1.13.
[n]See 8.4.1.14.
[o]See 8.4.1.15.

8.4.1.10* Materials used to fabricate miscellaneous, discontinuous small parts (such as knobs, rollers, fasteners, clips, grommets, and small electrical parts) that will not contribute materially to fire growth in end use configuration shall be exempt from flammability and smoke emission performance requirements, provided that the surface area of any individual small part is less than 100 cm^2 (16 $in.^2$) in end use configuration and an appropriate fire hazard analysis is conducted that addresses the location and quantity of the materials used and the vulnerability of the materials to ignition and contribution to flame spread.

8.4.1.11 Carpeting used as a wall or ceiling covering shall be tested according to ASTM E 162 and ASTM E 662 and shall meet the respective criteria of $I_s \leq 35$, D_s (1.5) ≤ 100, and D_s (4.0) ≤ 200. *(See 8.4.1.1 and 8.4.1.2.)*

8.4.1.12 If padding is used in the actual installation, floor covering shall be tested with padding in accordance with NFPA 253 or ASTM E 648.

8.4.1.13 Penetrations (ducts, etc.) shall be designed against acting as passageways for fire and smoke, and representative penetrations of each type shall be included as part of test assemblies.

8.4.1.14* See Section 8.5.

8.4.1.15* Portions of the vehicle body that separate the major ignition source, energy sources, or sources of fuel load from vehicle interiors shall have fire resistance as determined by a fire hazard analysis acceptable to the authority having jurisdiction that addresses the location and quantity of the materials used, as well as vulnerability of the materials to ignition, flame spread, and smoke generation. These portions shall include equipment-carrying portions of a vehicle's roof and the interior structure separating the levels of a bi-level car but do not include a flooring assembly subject to Section 8.5. In those cases, the use of the NFPA 251 (ASTM E 119) test procedure shall not be required.

8.4.2* Materials intended for use in a limited area of the vehicle and not meeting the requirements of Table 8.4.1 shall be permitted only after an appropriate fire hazard analysis establishes, within the limits of precision, that the material produces a contribution to fire hazard equal to or less than a material meeting the appropriate criteria of Table 8.4.1, where the alternative material is used in the same location to fulfill a function similar to the candidate material.

8.5 Fire Performance.

8.5.1 Assembly Testing.

8.5.1.1 Floor Assembly. All vehicle floor assemblies shall be tested as specified in 8.5.1.3.

8.5.1.1.1 Test Sample Size and Loading.

8.5.1.1.1.1 The size of the exposed portion of the floor assembly shall be at least 3.7 m (12 ft) long by the normal width of the vehicle floor.

8.5.1.1.1.2 The floor assembly shall be tested with a representative loading consistent with the vehicle design.

8.5.1.1.1.3 The loading shall take into consideration the dead weight of items on the floor, dead loads due to equipment above and below the floor, the weight of a crush load of passengers, and other relevant design loads.

8.5.1.2 Roof Assembly.

8.5.1.2.1 Vehicles that contain propulsion equipment or equipment that operates at voltages higher than 600 V on the roof shall demonstrate roof assembly fire resistance testing as specified in 8.5.1.3.

8.5.1.2.2 Vehicles that travel through tunnels and have a roof that is constructed of a combustible material shall require a fire hazard analysis to demonstrate that rapid fire spread to passenger and crew compartments or local roof collapse is not possible during the exposure period.

8.5.1.3 Test Details. Fire resistance testing on assemblies shall be conducted in accordance with NFPA 251 or ASTM E 119.

8.5.1.3.1 Test assemblies shall be representative of the vehicle construction and shall be tested in a configuration to demonstrate that a fire will not extend into the passenger and crew areas during the fire exposure duration.

8.5.1.3.1.1 Unexposed side thermocouples shall be installed in accordance with NFPA 251 or ASTM E 119.

8.5.1.3.1.2 The support of the test sample shall be limited to the transverse ends of the test sample only.

8.5.1.3.1.3 The test assembly shall contain one of each type of penetration included in the assembly construction.

(A) Penetrations shall be installed in the test assembly in accordance with Section 7 of ASTM E 814.

(B) In cases in which there are multiple sizes of the same type of penetration, the penetration determined to be the most likely to allow hot gas or flame passage shall be included in the assembly.

(C) No temperatures shall be required to be measured at the penetrations.

8.5.1.3.2 The minimum fire exposure duration shall be the greater of the following:

(1)*Twice the maximum expected time period under normal circumstances for a vehicle to stop completely and safely from its maximum operating speed, plus the time necessary to evacuate a full load of passengers from the vehicle under approved conditions
(2)*15 minutes for automated guideway transit (AGT) vehicles, 30 minutes for all other passenger-carrying vehicles

8.5.1.3.3 During the entire fire exposure, the following parameters shall apply:

(1) Transmission of heat through the assembly shall not be sufficient to raise the temperature on its unexposed surface more than 139°C (250°F) average and 181°C (325°F) single point.
(2)*The assembly shall not permit the passage of flame or gases hot enough to ignite cotton waste on the unexposed surface of the assembly.
(3) The assembly shall support the representative loading.

8.5.2 Vehicle Sides and Ends. A fire hazard analysis shall be conducted to demonstrate that fires originating outside the vehicle shall not extend into the passenger and crew areas before the vehicle is evacuated.

8.5.3 Equipment Lockers.

8.5.3.1 Portions of the vehicle that separate isolating electric equipment greater than 300 V and related wiring from the passenger and crew areas shall be lined with an arc-resistant lining.

8.5.3.2 Penetrations and access panels located between the locker and the passenger and crew areas shall be tested in accordance with ASTM E 814 and shall have an F rating of 15 minutes.

8.5.3.2.1 The separation assembly shall not allow the passage of flame for the entire exposure duration.

8.6 Electrical Fire Safety.

8.6.1 General Construction. All motors, motor control, current collectors, and auxiliaries shall be of a type and construction suitable for use on fixed guideway transit and passenger rail vehicles.

8.6.2 Clearance and Creepage.

8.6.2.1 Electrical Circuit. Electrical circuits and associated cabling shall be designed with clearance and creepage distance between voltage potentials and car body ground considering the environmental conditions to which the circuits and cabling will be subjected.

8.6.2.2* Air Clearance. The air clearance distances between voltage potentials (up to 2000 V) and ground shall comply with the following formula:

$$\text{Clearance (mm)} = 3.175 + (0.0127 \times \text{nominal voltage})$$
$$[\text{Clearance (in.)} = 0.125 + (0.0005 \times \text{nominal voltage})]$$

8.6.2.3 Creepage Distance.

8.6.2.3.1 Creepage distance for voltage potentials (up to 2000 V) to ground in ordinary enclosed environments shall comply with the following formula:

$$\text{Creepage (mm)} = 3.175 + (0.047625 \times \text{nominal voltage})$$
$$[\text{Creepage (in.)} = 0.125 + (0.001875 \times \text{nominal voltage})]$$

8.6.2.3.2* In other than ordinary enclosed environments, creepage distances shall be modified according to the anticipated severity of the environment.

8.6.3 Propulsion Motors.

8.6.3.1 Rotary motors shall be rated and tested in accordance with IEEE 11. Linear induction motors shall be rated and tested in accordance with IEC 62520.

8.6.3.2 Motor leads shall have insulation suitable for the operating environment.

8.6.3.3 Motor leads shall be supported and protected against mechanical damage.

8.6.3.4 Motor leads, where entering the frame, shall be securely clamped and shall fit snugly to prevent moisture from entering the motor case.

8.6.3.5 Drip loops shall be formed in motor leads to minimize water running along the lead onto the motor case.

8.6.3.6 The current value used in determining the minimum size of motor leads shall be no less than 50 percent of the maximum load current seen under the most severe normal duty or as determined by root-mean-square (rms) calculation, whichever is greater.

8.6.3.7 Car-borne propulsion configurations other than those for rotary motors shall be designed and constructed to provide a similar level of rating and testing as that for rotary motors.

8.6.4 Motor Control.

8.6.4.1 Motor control shall be rated and tested in accordance with IEEE 16.

8.6.4.2 Control equipment enclosures shall be arranged and installed to provide protection against moisture and mechanical damage.

8.6.4.3 Metal enclosures that surround arcing devices shall be lined with insulating material unless otherwise permitted in 8.6.4.5.

8.6.4.4 Shields or separations shall be provided to prevent arcing to adjacent equipment and wiring.

8.6.4.5 Metal enclosures shall not be required to be lined where the arc chutes extend through the enclosure and vent the arc to the outside air.

8.6.5 Propulsion and Braking System Resistors.

8.6.5.1* Self-ventilated propulsion and braking resistors shall be mounted to prevent ignition and dissipate heat away from combustible train materials.

8.6.5.2 Heat-resisting barriers of at least 6 mm (¼ in.) noncombustible insulating material or of sheet metal not less than 1 mm (0.04 in.) thick shall be installed extending horizontally beyond resistor supports to ensure protection from overheated resistors.

8.6.5.3 Forced ventilated resistors shall be mounted as follows:

(1) In ducts, enclosures, or compartments of noncombustible material
(2) With air space between the resistor enclosure and combustible materials

8.6.5.4 Provisions shall be made to filter the air where the operating environment is severe.

8.6.5.5 Power resistor circuits shall incorporate protective devices for the following failures:

(1) Ventilation airflow, if appropriate
(2) Temperature controls, if appropriate
(3) Short circuit in supply wiring, if appropriate

8.6.5.6 Resistor elements, resistor frames, and support shall be electrically insulated from each other.

8.6.5.7 The insulation shall be removed from resistor leads a minimum of 75 mm (3 in.) back from their terminals except where such removal introduces potential grounding conditions.

8.6.5.8 Where forced ventilation is provided, the resistor leads shall be separated, secured, and cleated for protection in the event of loss of air circulation of the ventilating system.

8.6.5.9 Leads shall be routed or otherwise protected from resistor heat.

8.6.5.10 The current value used in determining the minimum size of resistor leads shall be no less than 110 percent of the load current seen by the lead under the most severe duty cycle or as determined by rms calculation.

8.6.6 Current Collectors.

8.6.6.1 The minimum size of current collector leads shall be determined by adding the maximum auxiliary loads to the propulsion motor loads.

8.6.6.2 The equivalent regenerative load shall be included in the propulsion system equipped with regenerative capability.
