8.6.6.3 For vehicles that have more than one current collector, all current-carrying components shall be sized for continuous operation in the event power collection to the vehicle is restricted to a single collector.

8.6.7 Wiring.

8.6.7.1 Electrical Insulation.

8.6.7.1.1 All wires and cables shall be resistant to the spread of fire and shall have reduced smoke emissions by complying with 8.6.7.1.1.1 or 8.6.7.1.1.2.

8.6.7.1.1.1 All wires and cables shall comply with the FT4/IEEE 1202 exposure requirements for cable char height and with ANSI/UL 1685 for total smoke released and peak smoke release rate.

8.6.7.1.1.2 Wires and cables listed as having adequate fire-resistant and low-smoke-producing characteristics, by having a flame travel distance that does not exceed 1.5 m (5 ft) and generating a maximum peak optical density of smoke of 0.50 and a maximum average optical density of smoke of 0.15 when tested in accordance with NFPA 262, shall be permitted for use instead of the wires and cables specified in 8.6.7.1.1.1.

8.6.7.1.2 Low voltage power and control wires and cables (i.e., less than 100 V ac and 150 V dc) shall comply with 8.6.7.1.1 and either of the following:

(1) The physical, mechanical, and electrical performance requirements of ICEA S-95-658/NEMA WC-70 or ICEA S-73-532/NEMA WC-57, as applicable
(2) The physical, mechanical, and electrical performance requirements of ANSI/UL 44 for thermosetting insulation and ANSI/UL 83 for thermoplastic insulation as applicable.

8.6.7.1.3* Communication and data cables shall comply with 8.6.7.1.1 and the corresponding specifications.

8.6.7.1.4 Wires and cables used for heat, smoke, or other detection system shall comply with 8.6.7.1.1 and one of the following:

(1) Be capable of having 15-minute circuit integrity when tested in accordance with IEC 60331-11
(2) Demonstrate that, if circuit integrity is tested during the vertical flame test, a current continues operating for at least 5 minutes during the test
(3) Have circuit integrity cable in accordance with *NFPA 70*

8.6.7.2 Minimum Wire Size. In no case shall single conductor wire (not part of multi-conductor cable) smaller than the following sizes be used:

(1) 14 AWG (cross-section 2.1 mm^2) for wire pulled through conduits or wireways or installed exposed between enclosures
(2) 22 AWG (cross-section 0.33 mm^2) for all wires, including those used on electronic units, equipment within a rack, cards, card racks, and wire laid in wireways

8.6.7.3 Cable and Wire Sizes.

8.6.7.3.1 Conductor sizes shall be selected on the basis of current-carrying capacity, mechanical strength, temperature and flexibility requirements, and maximum allowable voltage drops.

8.6.7.3.2 Conductors shall be no smaller than the minimum sizes specified in 8.6.7.2.

8.6.7.3.3 Conductors shall be derated for grouping and shall be derated for ambient temperature greater than the manufacturer's design value in accordance with criteria specified by the authority having jurisdiction.

8.6.7.4 Wiring Methods.

8.6.7.4.1 Conductors of all sizes shall be provided with mechanical and environmental protection and shall be installed, with the exception of low-voltage dc circuits, in any one of, or combination of, the following ways:

(1) In raceways: metallic and nonmetallic, rigid or flexible
(2) In enclosures, boxes, or cabinets for apparatus housing
(3) Exposed: cleated, tied, or secured by other means

8.6.7.4.2 Firestops shall be provided in raceways.

8.6.7.4.3 Wires connected to different sources of energy shall not be cabled together or be run in the same conduit, raceway, tubing, junction box, or cable unless all such wires are insulated for the highest rated voltage in such locations or unless physical separation is provided.

8.6.7.4.4 Wires connected to electronic control apparatus shall not touch wires connected to a higher voltage source of energy than control voltage.

8.6.7.4.5 Conduits, electrical metallic tubing, nonmetallic ducts or tubing, and all wires with their outer casings shall be installed as follows:

(1) Extended into devices and cases where practicable
(2) Rigidly secured in place by means of cleats, straps, or bushings to prevent vibration or movement and to give environmental protection
(3) Run continuously into junction boxes or enclosing cases and be securely fastened to those devices

8.6.7.4.6 Splices outside of junction boxes shall be approved.

8.6.7.4.7 Connections and terminations shall be made in a manner to ensure their tightness and integrity.

8.6.7.4.8 Conductors and enclosures of any kind shall be protected from the environment and from mechanical damage, including damage from other larger conductors.

8.6.8 Overload Protection.

8.6.8.1 Propulsion Line Breaker.

8.6.8.1.1 A main, automatic circuit line breaker or line switch and overload relay for the protection of the power circuits shall be provided.

8.6.8.1.2 The circuit breaker arc chute shall be vented directly to the outside air.

8.6.8.2 Main Fuse Protection.

8.6.8.2.1 Cartridge-type fuses, if used in addition to the automatic circuit breaker, shall be installed in approved boxes or cabinets.

8.6.8.2.2 Railway-type ribbon fuses, if used, shall be in boxes designed specifically for this purpose and shall be equipped with arc blowout aids.

8.6.8.2.3 Third-rail shoe fuses mounted on the shoe beams shall be mounted to direct the arc away from grounded parts.

8.6.8.3 Auxiliary Circuits.

8.6.8.3.1 Circuits used for purposes other than propelling the vehicle shall be connected to the main cable at a point between the current collector and the protective device for the traction motors.

8.6.8.3.2 Each circuit or group of circuits shall be provided with at least one circuit breaker, fused switch, or fuse located as near as practicable to the point of connection of the auxiliary circuit.

8.6.8.3.2.1 Protection shall be permitted to be omitted in circuits controlling safety devices.

8.6.9 Battery Installation. Batteries and their associated circuitry shall be installed with the following requirements:

(1) Battery charging systems shall be designed to prevent overcharging of the battery.
(2) The battery shall be designed with an emergency cutoff system.
(3) The battery installation area shall be provided with a heat, smoke, or other fire detection system as appropriate for the environment in which it will operate.
(4) The battery installation area shall be separated from the car interior by the use of materials that are noncombustible, in accordance with the requirements of ASTM E 136.
(5) The battery installation area shall not use materials with hygroscopic properties.
(6) The battery installation area shall be provided with sufficient diffusion and ventilation of the gases from the battery to prevent the accumulation of an explosive mixture.
(7) Battery casing material shall comply with a radiant panel index that does not exceed 35 when tested in accordance with ASTM E 162, with specific optical density of smoke at 4 minutes into the test that does not exceed 200, and with specific optical density at 1.5 minutes that does not exceed 100 when tested in accordance with ASTM E 662 at the thickness of the casing material used in the battery.

8.7 Ventilation. Vehicles shall have provisions to deactivate all ventilation systems manually or automatically.

8.8 Emergency Egress Facilities.

8.8.1* Each vehicle shall be provided with a minimum of two means of emergency egress located on the sides or at the end(s), installed as remotely from each other as practicable.

8.8.1.1* Alternative means of emergency egress, including roof hatches as necessary for the type of vehicle, shall be approved.

8.8.2 A means to allow passengers to evacuate the vehicle safely to a walk surface or other suitable area under the supervision of authorized employees in case of an emergency shall be provided.

8.8.3 Emergency Lighting.

8.8.3.1* Emergency lighting facilities shall be provided such that the level of illumination of the means of egress conforms to the following:

(1) A minimum average illumination level of 10 lx (0.93 ft-candle), measured at the floor level adjacent to each interior door, with each interior door providing access to an exterior door (such as a door opening into a vestibule) or other emergency egress facility
(2) A minimum average illumination level of 10 lx (0.93 ft-candle), measured 610 mm (24 in.) above floor level along the center of each aisle and passageway
(3) A minimum illumination level of 1 lx (0.093 ft-candle), measured 610 mm (24 in.) above floor level at any point along the center of each aisle and passageway

8.8.3.2 The emergency lighting system power shall be automatically obtained from storage batteries.

8.8.3.3* The emergency lighting system storage batteries shall have a capacity capable of maintaining the lighting illumination level at not less than 60 percent of the minimum light levels specified in 8.8.3.1 for a period of time to permit evacuation but in no case less than the following periods:

(1) 60 minutes for a fixed guideway transit vehicle
(2) 90 minutes for a passenger rail vehicle

8.8.4* Operation of Means of Emergency Egress. Means of emergency egress using doors, windows, or roof hatches shall be capable of being operated manually from the interior and exterior of the vehicle without special tools.

8.8.5* Marking and Instructions for Operation of Means of Emergency Egress.

8.8.5.1 Interior.

8.8.5.1.1 A sign visible at all lighting levels that clearly and conspicuously identifies the means of emergency egress shall be provided adjacent to the means of emergency egress.

8.8.5.1.2 Instructions for the operation of the vehicle means of emergency egress shall be at or near the means of emergency egress.

8.8.5.1.3 Signs and instructions required by 8.8.5.1.1 and 8.8.5.1.2 shall meet the requirements of APTA SS-PS-002.

8.8.5.2 Exterior. The location and instructions for the operation of vehicle means of emergency access shall be legibly marked on or near the means of egress on the outside of the vehicle with retroreflective material in accordance with APTA SS-PS-002.

8.9 Protective Devices.

8.9.1 General. During normal vehicle operation, protective devices shall not introduce new hazards.

8.9.2 Communications.

8.9.2.1 Each vehicle, except as required in 8.9.2.2, shall be equipped with a communication system consisting of the following:

(1) A public address (PA) system whereby the train crew personnel, and, at the option of the authority, the operations control center can make announcements to the passengers
(2) A radio system whereby the train operator can communicate with the operations control center
(3) An intercommunication system whereby the train crew can communicate with one another
(4) At the option of the authority, a device that can be used by passengers to alert the operator of an emergency

8.9.2.2 Each AGT system vehicle shall be equipped with a communication system consisting of the following:

(1) A PA system whereby the operations control center can make announcements to the passengers
(2) A system whereby the passengers can communicate with the operations control center

8.9.2.3 Unauthorized opening of doors or emergency exit facilities on vehicles shall be automatically communicated to the operations control center or train operator.

8.9.3 Portable Fire Extinguishers.

8.9.3.1 Each vehicle or operator's cab shall be equipped with an approved portable fire extinguisher, unless otherwise permitted in 8.9.3.3.

8.9.3.2 Portable fire extinguishers shall be selected, inspected, and maintained in accordance with NFPA 10.

8.9.3.3 Portable fire extinguishers shall not be required in the vehicle or cab where sufficient wayside extinguishers, standpipe systems, or other fire-fighting equipment is available.

8.9.4 Lightning Protection.

8.9.4.1 Each vehicle that is supplied power from the overhead electrical contact wire shall be provided with a suitable and effective lightning arrester for the protection of all electrical circuits.

8.9.4.2 Lightning arresters on vehicles shall have a grounding connection of not less than 6 AWG or cross-section of 13.3 mm^2 and be run in as straight a line as possible to the ground.

8.9.4.2.1 Lightning arresters shall be properly protected against mechanical injury.

8.9.4.2.2 The grounding conductor shall not be run in metal conduit unless such conduit is bonded to the grounding conductor at both ends.

8.9.5 Heater Protection.

8.9.5.1 All heater elements shall incorporate protective devices for the following failures:

(1) Ventilation airflow, if appropriate
(2) Failure of temperature controls or occurrence of overtemperature conditions, as appropriate
(3) Short circuits and overloads in supply wiring

8.9.5.2 Heater-forced air distribution ducts shall incorporate overtemperature sensors, fusible links, airflow devices, or other means to detect overtemperature or lack of airflow.

8.9.6 Testing and Maintenance.

8.9.6.1 Qualification testing shall be performed by the equipment manufacturer in accordance with the following:

(1) IEEE 16
(2) IEEE 11
(3) Any additional tests specified by the AHJ

8.9.6.2 Periodic maintenance shall be performed in accordance with maintenance manuals furnished by the equipment manufacturer.

8.9.6.2.1 The degree and the frequency of maintenance shall be based on operating experience as determined by the authority.

8.10 Vehicle Support and Guidance System.

8.10.1 The vehicle support and guidance system (i.e., wheels, tires, magnetic or pneumatic levitation) shall be capable of safely supporting and guiding the vehicle in normal service.

8.10.2 Failure of the support, guidance, or levitation system shall not result in a condition that is unsafe to passengers.

8.10.3 Under loss of guideway clearance, the system shall be capable of safe operation until such time that the failure is detected by operation or maintenance personnel and the vehicle is taken out of service.

8.11 Engineering Analysis Option.

8.11.1* General. The requirements of this section shall apply to fixed guideway and passenger rail vehicles designed to meet the engineering analysis option permitted by Section 8.2 and to meet the goals and objectives stated in Sections 4.2 and 4.3.

8.11.1.1 In the application of Section 8.11, engineering analysis design activities shall be carried out by an individual or entity having qualifications acceptable to the authority having jurisdiction.

8.11.1.2 In the application of Section 8.11, the design, engineering analysis, and documentation shall be approved.

8.11.2* Basis for Engineering Analysis.

8.11.2.1 For this engineering analysis option, the broad goals and objectives specified in Sections 4.2 and 4.3 shall be converted into specific performance criteria based on the unique features and operating environment of the vehicle.

8.11.2.2 These specific criteria shall be used as the basis of the engineering analysis.

8.11.3 Retained Prescriptive Requirements. Retained prescriptive requirements shall be those specified in Sections 8.7 through 8.10.

8.11.4 Independent Review. The authority having jurisdiction shall, at its discretion, require an approved, independent third party to review the proposed design to provide an evaluation of the design.

8.11.5 Sources of Data.

8.11.5.1 Data sources used in performance-based design activities shall be identified and documented for each input data requirement that must be met, using a source other than a design fire scenario, an assumption, or a vehicle design specification.

8.11.5.2 The degree of conservatism reflected in such data shall be specified, and a justification for the source shall be provided.

8.11.6 Maintenance of Design Features.

8.11.6.1 Design features required to meet performance goals and objectives of this standard shall be intrinsic to the vehicle design or capable of being maintained throughout the life of the vehicle.

8.11.6.2 All documented assumptions, design specifications, and operating environment criteria shall be complied with throughout the life of the vehicles, such that vehicles continue to satisfy the goals and objectives specified in Sections 4.2 and 4.3.

8.11.6.3 Any variations made to vehicle original design features that affect life safety and fire protection shall be approved prior to the actual change being made.

Chapter 9 Emergency Procedures

9.1 General.

9.1.1 The authority responsible for the safe and efficient operation of a fixed guideway transit or passenger rail system shall anticipate and plan for emergencies that could involve the system.

9.1.2 Participating agencies shall be invited to assist with the preparations of the emergency procedure plan.

9.1.3 The emergency response agencies shall review and approve the emergency procedures plan prior to its implementation.

9.2 Emergency Management.

9.2.1 Operational procedures for the management of emergency situations shall be predefined for situations within the fixed guideway transit or passenger rail system.

9.2.2 Operational procedures shall be recorded, accessible, and managed from a dedicated source at the operations control center.

9.2.3 Passengers shall be advised and informed during an emergency, to discourage panic or stress during adverse circumstances.

9.2.4* Personnel whose duties take them onto the operational system shall be trained for emergency response pending the arrival of jurisdictional personnel.

9.2.5 Emergency personnel training shall be kept current through periodic drills and review courses.

9.3 Emergencies. The emergency management plan shall address the following types of emergencies:

(1) Fire or smoke conditions within the system structures, including stations, guideways (revenue or nonrevenue), and support facilities
(2) Collision or derailment involving the following:
  (a) Rail vehicles on the guideway
  (b) Rail vehicles with privately owned vehicles
  (c) Intrusion into the right-of-way from adjacent roads or properties
(3) Loss of primary power source resulting in stalled trains, loss of illumination, and availability of emergency power
(4) Evacuation of passengers from a train to all right-of-way configurations under circumstances where assistance is required
(5) Passenger panic
(6) Disabled, stalled, or stopped trains due to adverse personnel/passenger emergency conditions
(7) Tunnel flooding from internal or external sources
(8) Disruption of service due to disasters or dangerous conditions adjacent to the system, such as hazardous spills on adjacent roads or police activities or pursuits dangerously close to the operational system
(9) Structural collapse or imminent collapse of the authority property or adjacent property that threatens safe operations of the system
(10) Hazardous materials accidentally or intentionally released into the system
(11) Serious vandalism or criminal acts, including terrorism
(12) First aid or medical care for passengers on trains and in stations
(13) Extreme weather conditions, such as heavy snows, high or low temperatures, sleet, or ice
(14) Earthquake
(15) Any other emergency as determined by the authority having jurisdiction

9.4* Emergency Procedures. Emergency procedures shall be developed to specifically address the various types of emergencies that might be experienced on the system and shall include, but not be limited to, the following:

(1) Identification of the type of emergency, name of authority, and the date the plan was adopted, reviewed, or revised, as applicable
(2) Policy, purpose, scope, and definitions
(3) Participating agencies and areas of responsibility, including governing officials and signatures of executives from each agency
(4) Safety procedures to be implemented specific to each type of emergency operation
(5) Purpose and operations of the operations control center and alternative location(s), as applicable
(6) Command post and auxiliary command post purposes, and operational procedures, as applicable
(7) Communications, types of communications available, procedures to maintain safe operation, and equipment to interface with responding agencies
(8) Fire and smoke emergency information and procedures, including the following:
  (a) Location of fire in station or support facility
  (b) Location of train in enclosed trainway and fire location on train
  (c) Fire detection systems/zones in stations
  (d) Fire protection systems and devices and their locations/points of initiating operation
  (e) Locations of exits from and entrances to the incident site, including vehicular routes
  (f) Emergency ventilation system components and locations of equipment and local controls
  (g) Special equipment locations/cabinets
  (h) Agency(ies) to be notified and their phone numbers
  (i) Agency in command prior to and after the arrival of the local jurisdiction emergency response personnel
  (j) The preplanned mode of ventilation system operation (exhaust or supply)
  (k) Preplanned passenger evacuation direction as coordinated with fan mode operation
  (l) Fire and emergency incidents on adjoining properties
(9) Procedures typically implemented by responding jurisdictions for various types of emergencies as appropriate to site configuration
(10) Maps or plans of complex areas of the system at a minimum, such as underwater tubes, multilevel stations, adjacencies to places of large public assembly, or other unique areas
(11) Any other information or data that participating agencies determine to be necessary to provide effective response

9.5* Participating Agencies. Participating agencies to be summoned by operators of a fixed guideway transit or passenger rail system to cooperate and assist, depending on the nature of the emergency, shall include the following:

(1) Ambulance service
(2) Building department
(3) Fire department
(4) Medical service
(5) Police department
(6) Public works (e.g., bridges, streets, sewers)
(7) Sanitation department
(8) Utility companies (e.g., gas, electricity, telephone, steam)
(9) Water department (i.e., water supply)
(10) Local transportation companies
(11) Red Cross, Salvation Army, and similar agencies

9.6 Operations Control Center (OCC).

9.6.1 The authority shall operate an OCC for the operation and supervision of the system.

9.6.2 The OCC shall be staffed by trained and qualified personnel.

9.6.3 The OCC shall have the essential apparatus and equipment to communicate with, supervise, and coordinate all personnel and trains operating in the system.

9.6.4 The OCC shall provide the capability to communicate with participating agencies.

9.6.4.1 Agencies such as fire, police, ambulance, and medical service shall have direct telephone lines or designated telephone numbers used for emergencies involving the system.

9.6.5 Equipment shall be available and used for recording radio and telephone communications during an emergency.

9.6.6 OCC personnel shall be thoroughly conversant with the emergency procedure plan and shall be trained to employ it effectively whenever required.

9.6.7 The OCC shall be located in an area separated from other occupancies by 2-hour fire resistance construction.

9.6.8 The area shall be used for the OCC and similar activities and shall not be jeopardized by adjoining or adjacent occupancies.

9.6.9* The OCC shall be protected by fire detection, protection, and extinguishing equipment so that there will be early detection and extinguishment of any fire in the OCC.

9.6.10 Alternative location(s) shall be provided in the event the OCC is out of service for any reason and shall be equipped or have equipment readily available to function as required by the authority.

9.7 Liaison.

9.7.1 An up-to-date listing of all liaison personnel from participating agencies shall be maintained by the authority and shall be part of the emergency procedure plan.

9.7.2 The listing shall include the full name, title, agency, business telephone number(s), and home telephone number of the liaison and of an alternative liaison.

9.7.3 At least once every 3 months, the list shall be reviewed and tested to determine the ability to contact the liaison without delay.

9.8 Command Post.

9.8.1* During an emergency on the system that requires invoking the emergency procedure plan, a command post shall be established by the incident commander for the supervision and coordination of all personnel, equipment, and resources at the scene of the emergency.

9.8.2 The emergency procedure plan shall clearly delineate the authority or participating agency that is in command and that is responsible for supervision, correction, or alleviation of the emergency.

9.8.3 Participating agencies shall each assign a liaison to the command post.

9.8.4 Radio, telephone, and messenger service shall be used to communicate with participating agencies operating at an emergency.

9.8.5* Approved markers shall be used to identify the command post.

9.8.6 The emergency procedure plan shall prescribe the specific identification markers to be used for the command post and for personnel assigned thereto.

9.9* Auxiliary Command Post. When an emergency operation requires an auxiliary command post because of the extent of the operation, the person in command shall establish an auxiliary command post(s) that will function as a subordinate control.

9.10 Training, Exercises, Drills, and Critiques.

9.10.1 The authority and participating agency personnel shall be trained to function during an emergency.

9.10.1.1 The training shall cover all aspects of the emergency procedure plan.

9.10.2 Exercises and drills shall be conducted at least twice per year to prepare the authority and participating agency personnel for emergencies.

9.10.3 Critiques shall be held after the exercises, drills, and actual emergencies.

9.10.4 Drills shall be conducted at various locations on the system as well as at various times of the day so as to prepare as many emergency response personnel as possible.

9.11 Records. Written records and telephone and radio recordings shall be kept at the OCC, and written records shall be kept at the command post and auxiliary command post(s) during fire emergencies, exercises, and drills.

9.12 Removing and Restoring Traction Power.

9.12.1 During an emergency, the authority and participating agency personnel shall be supervised so that only the minimum number of essential persons operate on the trainway.

9.12.2 The emergency procedure plan shall have a defined procedure for removing and restoring traction power.

9.12.3 Before participating agency personnel operate on the trainway, the traction power shall be removed.

9.12.4 Traction power disconnect devices shall allow quick removal of power from power zones. Emergency shutoff of traction power shall be either by activation of traction power disconnect devices or by communication with OCC to request the traction power be disconnected.

9.12.5 When traction power is removed by activation of an emergency traction power disconnect switch, the OCC shall be contacted by telephone or radio and given the full name, title, agency, and reason for removal of the traction power by the person responsible.

9.12.6 When shutdown of traction power is no longer required by a participating agency, control of such power shall be released to the authority.

Chapter 10 Communications

10.1* General. A communication system shall be established in accordance with this chapter.

10.2 Operations Control Center (OCC) and Command Post Relationship.

10.2.1 During normal operations, the OCC shall be the primary control for the system.

10.2.2 During emergency operations, the command post established at the scene of the emergency shall be responsible for controlling, supervising, and coordinating personnel and equipment working to correct or alleviate the emergency.

10.2.3 The command post and OCC shall cooperate and coordinate to have an efficient operation.

10.2.4 The OCC shall be responsible for operation of the system except for the immediate emergency area.

10.3 Radio Communication.

10.3.1 A fixed guideway transit or passenger rail system shall have at least one radio network that is capable of two-way communication with personnel on trains, motor vehicles, and all locations of the system.

10.3.2 Wherever necessary for reliable communications, a separate radio network capable of two-way radio communication for fire department personnel to the fire department communication center shall be provided.

10.3.3 A radio network shall comprise base transmitters and receivers, antennas, mobile transmitters and receivers, portable transmitters and receivers, and ancillary equipment.

10.4 Telephone.

10.4.1 An emergency telephone (ETEL) shall be provided along the trainway at each blue light station and at other locations deemed necessary by the authority having jurisdiction.

10.4.2 The system shall have a telephone network of fixed telephone lines and handsets capable of communication with all stations, fire command centers, structures, offices, power stations and substations, control towers, ancillary rooms and spaces, and locations along the trainway in accordance with *NFPA 72*.

10.4.3 The location and spacing of telephones along the trainway shall be determined by the authority having jurisdiction.

10.4.4 Telephones along the trainway shall have distinctive signs or lights or both for identification.

10.4.5 Telephone locations shall be automatically identified in the OCC or other approved location.

10.5 Portable Telephones and Lines.

10.5.1 The authority shall maintain portable communications equipment and arrange for the dispatch to an emergency scene where required for emergency operations or requested by emergency responders.

10.5.2 The authority having jurisdiction shall approve the type of communications equipment.

10.6 Public Address (PA) System.

10.6.1 All stations, as determined by the authority having jurisdiction, shall have a PA system for communicating with passengers and employees. *(For communication requirements for vehicles, see 8.9.2.)*

10.6.2 The OCC shall have the capability of using the PA system to make announcements throughout stations.

10.6.3 Authority supervisory employees and emergency response personnel at stations shall have the capability of making announcements throughout public areas on the PA system.

10.6.4 During interruptions of train service or delays for any reason associated with an emergency, fire, or smoke, the passengers and employees shall be kept informed by means of the PA system.

10.6.5 At times of emergency, the PA system shall be used to communicate with passengers, employees, and participating agency personnel.

10.7 Portable Powered Speakers (Audiohailers). During emergency operations, portable powered speakers shall be made available by the authority where other forms of communication are not available.

Chapter 11 Control and Communication System Functionality, Reliability, and Availability

11.1 General.

11.1.1 Scope. This chapter defines requirements for the functionality, reliability and availability of control systems and communication systems when exposed to the effects of smoke and fire.

11.1.2 Application. These systems include the following:

(1) Train control (signaling systems) as described in 7.2.4, 8.9.2.3, and in this chapter
(2) Emergency communication systems as described in 6.4.2, 8.9.2.1, 8.9.2.2, 9.8.4, and 9.9
(3) Traction power systems as described in 6.4.2, 7.2.4, 9.12.4, and 9.12.5
(4) Supervisory control and data acquisition (SCADA) systems as they apply to fire emergencies

11.2 Train Control.

11.2.1* A reliability analysis shall be performed to consider the ability of control systems to maintain communications and the ability to reposition vehicles during a fire emergency.

11.2.2 Systems with and without an onboard operator shall be reviewed for the functionality, reliability, and availability of their control and communication systems during a fire incident.

11.2.3 For fixed guideway and passenger rail systems that do not have an operator on board, the controls shall accommodate the remote repositioning of trains.

11.2.3.1 If a train is immobile and on fire, the ability of the control system to move other trains away from the immobile train in a timely manner, addressing the concerns of passenger life safety, shall be accounted for as part of the overall system design.

11.2.3.2 If a train is exposed to an exterior fire, the ability of the control system to move the train away from the fire in a timely manner, addressing the concerns of passenger life safety, shall be accounted for as part of the overall system design.

11.2.4 For systems with an operator on board, procedures shall be developed to address train movement.

11.2.4.1 If a train is immobile and on fire, the ability of the control system to move other trains away from the immobile train in a timely manner, addressing the concerns of passenger life safety, shall be accounted for as part of the overall system design.

11.2.4.2 If a train is exposed to an exterior fire, the ability of the control system to move the train away from the fire in a timely manner, addressing the concerns of passenger life safety, shall be accounted for as part of the overall system design.

11.3 Functionality, Reliability, and Availability of Control Systems.

11.3.1* Functionality, reliability, and availability of control systems and communications systems during a fire incident shall be considered in addition to normal reliability and availability calculations.

11.3.2* To meet the goals for life safety of the occupants, the effects of single points of failure shall be considered.

11.3.3* In addition to physical protection from incidents, control, data, and communication cables and related components shall continue functionality during a fire and shall be protected from thermal exposure that would affect their function.

Chapter 12 Wire and Cable Requirements

12.1 General.

12.1.1 Scope. This chapter applies to wires and cables in all locations except in those vehicles addressed in Chapter 8.

12.1.2* All wiring materials and installations other than for traction power shall conform to the requirements of *NFPA 70* except as modified herein.

12.2 Flame Spread and Smoke Release.

12.2.1 All wires and cables used shall be listed as being resistant to the spread of fire and shall have reduced smoke emissions, by complying with one of the following:

(1) All wires and cables shall comply with the FT4/IEEE 1202 exposure requirements for cable char height, total smoke released, and peak smoke release rate of ANSI/UL 1685.
(2) Wires and cables listed as having adequate fire-resistant and low-smoke producing characteristics, by having a flame travel distance that does not exceed 1.5 m (5 ft) and generating a maximum peak optical density of smoke of 0.50 and a maximum average optical density of smoke of 0.15 when tested in accordance with NFPA 262, shall be permitted for use instead of the wires and cables specified in item (1).

12.3 Temperature, Moisture, and Grounding Requirements.

12.3.1 Wires and cables shall comply with both of the following temperature and moisture resistance characteristics:

(1) All insulations shall conform to *NFPA 70* and shall be a moisture- and heat-resistant type carrying a temperature rating of 90°C (194°F).
(2) All insulated conductors and cables shall be listed for wet locations.

12.3.2 Ground wires shall comply with the following:

(1) Ground wires installed in a metallic raceway shall be insulated.
(2) In underground stations and trainways, other ground wires shall be permitted to be bare.

12.4 Wiring Installation Methods.

12.4.1 Conduits, raceways, ducts, boxes, cabinets, and equipment enclosures shall be constructed of noncombustible materials. In stations, other materials when encased in concrete shall be acceptable.

12.4.2 All conductors, except radio antennas, shall be enclosed in their entirety in armor sheaths, conduits, or enclosed raceways, boxes, and cabinets except in ancillary areas.

12.4.3 Within the emergency ventilation air distribution system, the following wiring methods are acceptable:

(1) Type MI cable without an overall protected nonmetallic covering
(2) Type MC cable employing a smooth or corrugated impervious metal sheath without an overall nonmetallic covering
(3) Conductors in electrical metallic tubing, flexible metallic tubing, intermediate metal conduit, or rigid metal conduit all without an overall nonmetallic covering

12.4.4 The emergency power, emergency lighting, and emergency communications circuits shall be protected from physical damage by system vehicles or other normal system operations and from fires in the system for at least 1 hour, but not less than the time of tenability, when exposed to fire conditions corresponding to the time-temperature curve in the ASTM E 119 fire resistance test by any of the following:

(1) Circuits are embedded in concrete or protected by a fire barrier system in accordance with UL 1724. The cables or conductors shall maintain functionality at the temperature within the embedded conduit or fire barrier system.
(2) Circuits are routed outside the underground portion of the system.
(3) There is diversity in system routing (such as separate redundant circuits or multiple circuits separated by a fire barrier with a fire resistance rating so that a single fire or emergency event will not lead to a failure of the system).
(4) All circuits consist of listed fire-resistive cable systems with a fire resistance rating in accordance with 12.5.

12.5 Fire-Resistive Cables.

12.5.1 Fire-resistive cables shall be certified or listed as having been tested in a totally enclosed furnace using the ASTM E 119 time temperature curve.

12.5.2 The cables shall demonstrate functionality for no less than 1 hour as described in the ANSI/UL 2196 test standard.

12.5.3* The cables and systems shall comply with the following:

(1) Be tested as a complete system of conductors, cables, and raceways, as applicable, using a sample no shorter than 3.0 m (9.84 ft)
(2) For fire-resistive cables intended for installation in a raceway, be tested in the type of raceway in which they are intended to be installed
(3) Have installation instructions that describe the tested assembly, with only the components included in the tested assembly acceptable for installation

Annex A Explanatory Material

Annex A is not a part of the requirements of this NFPA document but is included for informational purposes only. This annex contains explanatory material, numbered to correspond with the applicable text paragraphs.

A.1.1.1 Vehicle maintenance facilities are not addressed by this standard because requirements for that occupancy are provided in other codes and standards. Where vehicle maintenance facilities are integrated or co-located with occupancies covered by this standard, special considerations beyond this standard shall be necessary.

A.1.1.3(6) A shelter stop is a location along a fixed guideway transit or passenger rail system for the loading and unloading of passengers that is located in a public way and is designed for unrestricted movement of passengers. A shelter stop can have a cover but no walls or barriers that would restrict passenger movement.

A.1.3.3 The nature of facility retrofitting should be assessed to determine the degree of applicability of the standard. For example, an upgrading retrofit might be undertaken as part of a due diligence initiative aimed at improving the level of compliance with the intent of the standard, while full compliance with all relevant requirements might not be achievable. Such retrofits should be permitted provided that, as a minimum, they maintain the existing performance level of the facility and specifically do not adversely affect the early warning and evacuation systems, fire separations, structural adequacy, or tenable environment in the facility.

A.1.4 Before a particular mathematical fire model or evaluation system is used, its purpose and limitations need to be known. Technical documentation should clearly identify any assumptions included in the evaluation. Also, it is the intent of this standard to recognize that future editions of this standard are a further refinement of this edition and earlier editions. The changes in future editions will reflect the continuing input of the fire protection/life safety community in its attempt to meet the purpose stated in this standard.

A.1.4.3 An equivalent method of protection provides an equal or greater level of safety. It is not a waiver or deletion of a requirement provided by a standard. The prescriptive provisions of this standard provide specific requirements for broad classifications of structures. These requirements are stated in terms of fixed values, such as maximum travel distance, minimum fire resistance ratings, and minimum features of required systems, such as detection, alarm, suppression, and ventilation, and not in terms of overall station, guideway, or vehicle system performance. However, the equivalency clause in 1.4.3 permits the use of alternative systems, methods, or devices to meet the intent of the prescribed provisions of a standard where approved as being equivalent. Equivalency provides an opportunity for a performance-based design approach. Through the rigor of a performance-based design, it can be demonstrated whether a station, guideway, or vehicle design is satisfactory and complies with the implicit or explicit intent of the applicable requirement provided by a standard. When the equivalency is used, it is important to clearly identify the prescriptive-based standard provision being addressed (scope), to provide an interpretation of the intent of the provision (goals and objectives), to provide an alternative approach (proposed design), and to provide appropriate support for the suggested alternative (evaluation of proposed designs). Performance resulting from proposed designs can be compared with the performance of the design features required by this standard. Using prescribed features as a baseline for comparison, it can then be demonstrated in the evaluation whether a proposed design offers the intended level of performance. A comparison of safety provided can be used as the basis for establishing equivalency.

A.3.2.1 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

A.3.2.2 Authority Having Jurisdiction (AHJ). The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A.3.2.4 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A.3.3.1 Airflow Control Devices. Air curtains have been used to minimize tunnel airflow in transit systems. Barriers are similar to life rafts with inflatable rings or collars and could be used to minimize tunnel airflow. Brattices are parachute- or curtain-like devices that have been used in mine headings to minimize airflow. Doors have been used to minimize tunnel airflow in transit systems. Downstands and enclosures have been used to minimize airflow and smoke movement in rail stations. Gates are guillotine-type doors mounted at tunnel portals and have been used in passenger rail tunnels to minimize tunnel airflow.

A.3.3.5 Blue Light Station. The definition states the minimum functional requirements for a blue light station. The design provisions to accomplish those functions, as well as the need for other functions or equipments, should be determined based on emergency response planning for the system.

A.3.3.11 Concourse. A concourse is distinct from a platform because it can be more open, and passenger speeds can be different from those prescribed for a platform, platform stair, or escalator.

A.3.3.15 Engineering Analysis. *Engineering analysis* is a broad term that encompasses a range of different objectives and performance criteria. The complexity of the analysis and the factors requiring consideration are situation dependent and require the user to have sufficient understanding of the objectives, assumptions, and analysis tools being implemented.

General examples from within this document include analysis intended to provide justification for the modification of evacuation time/travel distance requirements, analysis to support the use of a concourse area as a point of safety, and analysis relative to the use of a nonmechanical ventilation system in lieu of a mechanical emergency ventilation system.

A written report of the analysis should be submitted to the authority having jurisdiction, indicating recommended fire protection method(s) that will provide a level of fire safety commensurate with this standard. The objectives, assumptions, sources of data, and degree of conservatism incorporated into the analysis should be addressed.

A.3.3.15.1 Fire Hazard Analysis. The term *fire hazard analysis* generally refers to analyses that are performed relative to the specific fire performance of materials, components, and assemblies for the purposes of addressing the subsequent contribution to the overall fire hazard and the resulting impact on occupant fire safety. A fire hazard analysis can provide an estimate of the potential severity of fires that can develop under defined fire scenarios. This analysis can encompass consideration of factors that include but are not limited to, quantities of materials, vulnerability of materials and components to ignition, propensity for flame spread, and smoke generation.

The formulation of a fire hazard analysis is subjective and dependent upon the expertise of the user. The material provided in Annex E, although specifically addressing fire hazard analysis for vehicles, provides additional guidance relative to the steps that might be involved in a fire hazard analysis. A written report of the analysis should be submitted to the authority having jurisdiction, indicating that a level of fire safety commensurate with this standard will be achieved.

A.3.3.20.1 Effective Fire Load. The effective fire load can include vehicle(s), luggage, fuel, and wayside facilities or structures, that, because of the fuel package configuration, separation, and combustion characteristics, would be expected to be released in a design fire incident.

A.3.3.20.2 Total Fire Load. The total fire load can include vehicle(s), luggage, fuel, and wayside facilities or structures.

A.3.3.27 Heat Release Rate (HRR). The heat release rate of a fuel is related to its chemistry, physical form, and availability of oxidant and is ordinarily expressed as Btu/sec or kilowatts (kW). [**921,** 2011]

A.3.3.44.2 Open Station. Direct dispersion is passing to atmosphere without ducting, without accumulation in occupied areas, and without entering or passing through another occupied level of the station.

A.4.2.1 The fire-life safety concepts in this standard are predicated and achieved by providing tenable conditions for evacuation of passengers described in this standard, as follows:

(1) Fire hazard control through use of fire-hardened materials in stations, tunnels, and trains
(2) Provision of fire detection, alarm notification, communication systems, and evacuation routes
(3) Natural ventilation or mechanical ventilation providing smoke control to maintain tenability
(4) Fire safety system reliability through system redundancy and increased safety in emergency system wires and cables that might be exposed to fire

The inclusion of automatic fire suppression systems in stations, tunnels, or trains provides an active system that can limit fire growth and thereby assist in reducing risk to life and property. Where such systems are provided, variations to requirements in this standard for materials, communications, systems, or reliability can be considered where supported by engineering analysis as permitted by Section 1.4 and in accordance with good fire protection engineering practice.

A.4.4 The standard was created to address the issue of entrapment and injury of large numbers of people who routinely use fixed guideway transit systems as a result of fire in the system. The document has evolved to now include passenger rail systems. The basis of the document — providing the minimum life safety from fire and fire protection requirements — still stands. It is not intended for the document to provide design basis for non-fire events such as explosions or other random acts of sabotage.

A.4.5 Freight operations are typically subject to regulation by others, and are beyond the scope of this standard. Freight operations can affect life safety from fire hazards due to concurrent operations.

The increased hazard includes the potential for rapid fire development to fire heat release rates that can exceed those of a non-freight vehicle, with combustible loads that might support fires that burn for days. The increased hazard also includes non-fire events involving release of materials hazardous to life. The design process should include information exchange and agreement among the freight operator, the passenger services operator and the authority having jurisdiction.

All concurrent freight and passenger uses should be given consideration. More detailed consideration of the relative life safety from fire hazards is strongly recommended when applied to underground facilities, where the confined nature of the space will magnify the hazards. Consideration should include implications of concurrent uses for freight systems operated through or adjacent to passenger stations and concurrent uses for freight systems operated through or adjacent to passenger trainways.

A.4.6 The location and size of a fire can greatly affect the degree of hazard to system occupants. Therefore, the system design must consider specific fire scenarios that could occur. Fire location and size are examples of factors that fire scenarios must consider:

(1) *Interior locations.* This scenario occurs from a fire that originates within a station or trainway or the interior passenger compartment of the vehicle. Examples of interior fire scenarios include the following:
    (a) Fire that begins from an incendiary ignition involving the use of accelerants
    (b) Trash fire
    (c) Electrical fire
    (d) Fire that occurs in a location used for food preparation
    (e) Luggage storage area fire
    (f) Fire that occurs from ignition by small open flame onto bedding in an unoccupied compartment in a vehicle that provides compartments for overnight sleeping
    (g) Fire that occurs where the vehicle rolls over onto its side and ignition occurs
(2) *Exterior locations.* This scenario occurs as a result of a fire originating outside the passenger compartment of the vehicle and penetrating the exterior of the vehicle. Examples of exterior fire scenarios include the following:
    (a) Electrical fire in the station, in the trainway, under the vehicle floor, or on the roof that burns through into the

passenger compartment or that causes the vehicle to stop between stations
   (b) Trash fire or other type of station, trainway, or under-vehicle equipment or floor fire
   (c) Fire that occurs from ignition of a fuel spill adjacent to the station, a trainway, or a vehicle involved in a collision
(3) *Operating environment.* Consequences can increase if a fire occurs when occupants are in the following locations:
   (a) In a station, trainway, or passenger-carrying vehicle that is in a stationary location and unable to move and where egress or rescue access could be hazardous (e.g., underground trainway or station)
   (b) In a passenger-carrying vehicle in motion between stations and at the maximum distance from any station, safe refuge, or point of safety

Fire scenarios that are appropriate for a particular system vehicle and operating environment could not be applicable to another system vehicle and operating environment.

A.4.7 The provisions of Section 4.7 do not require inherently noncombustible materials to be tested in order to be classified as noncombustible materials.

A.4.7.1 Examples of such materials include steel, concrete, masonry, and glass.

A.4.8 Fire-life safety systems comprise interdependent mechanical, electrical, communications, control, fire protection, structural, architectural, and other elements, all of which must function as a system to achieve the designed result. It is critical that all primary and supporting elements are protected to a similar level of reliability for the design incident exposure.

A.5.1.2 This subsection is specifically intended to refer to features that normally would be required in the design and construction of stations. It is not intended to apply to trainways or to invoke requirements that normally would not be applicable in the design of a building similar in size or configuration to a station.

A.5.2.1.4 See A.6.3.4.3.

A.5.2.4.1(1) This requirement is intended to refer to stairs and escalators used for normal revenue service. Fire-separated exit stairs can also be required in order to satisfy the requirements of 5.3.3.7 for alternate egress or 5.3.5.5 for the proportion of escalators counted as means of egress.

A.5.2.4.2 The fire resistance rating of the required fire separation should be determined based on evaluation of such factors as the type of station configuration (open versus enclosed), fire suppression provided in the nonpublic areas, and NFPA *101* requirements for separation of similar occupancies.

A.5.2.4.4 The fire resistance rating of the required fire separation should be determined based on evaluation of such factors as the type of station configuration (open versus enclosed), fire suppression provided in the nonpublic areas, and NFPA *101* requirements for separation of similar occupancies.

A.5.2.4.5 Because of the difference in the potential level of hazard between various stations (e.g., open stations compared to enclosed stations), alternative methods to fire separation could be considered.

A.5.2.6.1 The fire hazard analysis should determine that the fire does not propagate beyond the component of fire origin and that a level of fire safety is provided within the station commensurate with this standard. Computer modeling, material fire testing, or full-scale fire testing should be conducted, as appropriate, to assess fire performance in potential fire scenarios.

A.5.2.6.2 Rubbish containers that are used in the station on a temporary basis (e.g., during cleaning operations) should be manufactured of noncombustible materials or of materials that comply with a peak heat release rate not exceeding 300 kW/m^2 (26.4 Btu/ft^2·sec) when tested in accordance with ASTM E 1354 at an incident heat flux of 50 kW/m^2 (4.4 Btu/ft^2·sec), in the horizontal orientation.

A.5.3 Annex C provides additional information and sample calculations relating to means of egress.

A.5.3.1 Where codes other than NFPA *101* are in effect, reference to NFPA *101* can be replaced by reference to relevant requirements in the locally applicable building code.

A.5.3.2.1 In that the peak ridership data are used to determine occupant load (and, consequently, required egress capacity), the basis for those data should be considered carefully.

The term *peak period* is intended to imply the time within the peak hour having the maximum passenger flow rate. For many systems, this period ranges between 10 minutes and 20 minutes in duration. Where peak hour ridership numbers are used, a surge factor should be applied as a distribution curve correction to account for the peak within the hour. Factors of 1.3 to 1.5 are typical for many systems. Other surge factors ranging from 1.15 to 2.75 have been reported.

In new systems, a survey of actual usage should be made within 2 years of completion of the project to verify design predictions. In operating systems, patronage levels should be projected to determine the need for expansion of the system or significant operating changes. Verification by survey should be made following any extension or significant operating change or at a maximum of 5-year intervals.

A.5.3.2.2 Consideration of control of the access to platforms might be necessary so that the station occupant load does not exceed the station egress capacity.

A.5.3.2.3(2) At multilevel, multiline, or multiplatform stations, it can be reasonable to consider only entraining (or entraining plus detraining) loads for nonincident levels for determining required egress capacity at points where egress troutes converge. Nonincident platform loads that do not adversely impact the egress route need not be considered.

A.5.3.2.5 The determination of maximum occupant load at a platform often requires comparison of calculations based on different peak periods. For example, to determine the maximum peak period platform occupant load for stations serving predominantly commuter ridership, the calculations described in 5.3.2.5(1) through 5.3.2.5(7) can be computed based on both the a.m. and the p.m. peak ridership for each platform and then compared to determine the maximum platform occupant load.

A.5.3.2.5(3) It is important that the load/headway capture the potential buildup of passengers that might occur before an emergency event is recognized as requiring evacuation. The determination of the appropriate accumulation factor should reflect system-specific characteristics such as the following:

(1) The type of system (e.g., automated/driverless vs. manually driven)
(2) The amount and type of surveillance
(3) The distance between stations and train headways

For systems with longer headways, a factor of two headways might be adequate to approximate accumulation and response time. For systems with very short headways, a fixed time (e.g., 5 minutes to 10 minutes) might be more appropriate to approximate the potential passenger buildup.

Consideration should also be given to whether the entraining and train loads should be subject to the same accumulation factor.

A.5.3.2.5(4) The nonincident service is not contributing detraining load.

A.5.3.3 The means of egress capacity factors and travel speeds are consistent with observed pedestrian movement within congested areas of passenger stations as represented by level of service E/F in *Pedestrian Planning and Design*, by Fruin. Patronage can vary for different user groups periodically or change over time. Modification could be warranted based on engineering analysis.

A.5.3.3.1 The stipulated time is intended as a baseline for determining the required capacity and maximum travel distances for platform egress routes. It is not intended that this calculation be required to account for delays due to products of combustion or debris along an egress route or delays due to the movement of those who are unable to achieve self-evacuation.

A.5.3.3.2 See A.5.3.3.1.

A.5.3.3.6 The determination of a common path of travel from the ends of a platform should consider the configuration (e.g., width and enclosure) of the platform versus the anticipated exposure to a train on fire at the platform. Where the platform is sufficiently wide to allow passengers to move away from the radiation effects of the train fire, it is reasonable to consider the egress from that platform as not creating a common path of travel.

A.5.3.3.7(1) This requirement is intended to replace the requirement in 7.3.1.1.2 of NFPA *101*, that the loss of one egress route must leave at least 50 percent of the egress capacity available. This approach is in recognition of the following design factors:

(1) Station design inherently requires primary circulation routes to be obvious and readily accessible such that preference for such routes would be anticipated in the event of an emergency evacuation.
(2) Requirements elsewhere in this standard (e.g., emergency ventilation in Chapter 7) require special protection of primary circulation routes from the effects of a train fire in enclosed stations.
(3) In the event of unavailability of one of the primary circulation routes due to another fire condition, the occupant load to be evacuated would be substantially less than that on which the size of the egress routes is determined, that is, the occupant load would not include the train link load.

A.5.3.3.8 Where automated spreadsheet calculations or computer-based software programs are used, the means of egress analysis should include documentation detailing all input parameters and algorithm(s).

A.5.3.4 Ramps are permitted in stations in accordance with NFPA *101* (and other applicable standards), which allows use of ramps with slopes up to 1:12 (8.33 percent)

A.5.3.4.1 The 2003 and previous editions of NFPA 130 required that exit corridors and ramps be a minimum of 1.73 m (5 ft 8 in.) wide. There is no technical basis for the previous minimum. The intent of 5.3.4.1 is to make NFPA 130 consistent with NFPA *101* relative to the minimum 1120 mm (44 in.) corridor width in the means of egress. NFPA 130 addresses means of egress conditions unique to transit/passenger rail facilities such as open platform edges. In NFPA *101*, means of egress facilities are based upon a function of the persons served (units of width/person served). NFPA 130 introduces a unit of time in determining the required egress width. This is necessary to demonstrate compliance with the performance requirements related to platform evacuation time and reaching a point of safety.

Assuming a 1120 mm (44 in.) wide side platform per 5.3.4.1 the effective platform width for egress is as follows:

$$1120\text{ mm} - 455\text{ mm }(\text{platform edge}) - 305\text{ mm }(\text{sidewall}) = 355\text{ mm}$$
$$[44\text{ in.} - 18\text{ in. (platform edge)} - 12\text{ in. (sidewall)} = 14\text{ in.}]$$

The capacity afforded by the effective 355 mm (14 in.) wide platform is:

$$355\text{ mm} \times 0.819\ \text{p/mm-min} = 29\ \text{p/min}$$
$$(14\text{ in.} \times 2.08\ \text{p/in.-min} = 29\ \text{p/min})$$

An effective 1120 mm (44 in.) wide corridor yields:

$$1120\text{ mm} \times 0.0819\ \text{p/mm-min} = 91\ \text{p/min}$$
$$(44\text{ in.} \times 2.08\ \text{p/in.-min} = 91\ \text{p/min})$$

It must be recognized that while strict interpretation of 5.3.4.1 indicates a station could be designed using a 1120 mm (44 in.) wide platform with an open edge and sidewall condition, it is impractical to do so, especially when one considers the other requirements of this standard that will affect the platform width, such as the travel distance to the point(s) of egress, the maximum 4-minute platform evacuation time, and the 6-minute point of safety time.

A.5.3.4.4 For ramps, various studies have reported that there were no statistically significant differences or measurable effect on walking speeds due to grades up to 5 or 6 percent, but that there is a gradual linear decline in speed for steeper grades.

A.5.3.4.5 See A.5.3.3 for clarification.

A.5.3.5.3 Where escalators having a nominal width of 1000 mm (40 in.) will be dedicated for operation in the direction of exit travel at speeds of at least 30 m/min (98 ft/min), such escalators can be permitted to be counted as having a capacity of 75 p/min. This should be considered appropriate only in conjunction with other provisions of this standard, such as the requirement to discount one escalator at each station level. Such escalators should also be connected to emergency power. This suggested speed is consistent with the maximum speed permitted in ASME A17.1/CSA B44, a bi-national standard. The suggested capacity is consistent with research reported in the *Elevator World* article “Escalator Handling Capacity” and in *Pedestrian Planning and Design*, by Fruin. Other codes regulating transit station design permit escalator capacity to be based on operating capacity (e.g., *Ontario Building Code*, Section 3.13, “Rapid Transit Stations,” and London Underground Ltd., *LUL Station Planning Guidelines*, which both permit a capacity of 100 p/min.). Designers are encouraged to research the latest available data. Unpublished research suggests that where the vertical rise exceeds 15 m (50 ft), the capacity and travel speed for stairs should be adjusted downward by approximately 30 percent to account for fatigue. Additionally, the design should provide enlarged landings to allow pedestrians to rest without impeding egress flow.

A.5.3.5.3(2) The vertical component of travel speed is calculated based on the vertical change in elevation between one station level and the next. [See Figure A.5.3.5.3(2).] See also *Application Guidelines for the Egress Element of the Fire Protection Standard for Fixed Guideway Transit Systems* and the example calculations in Annex C.

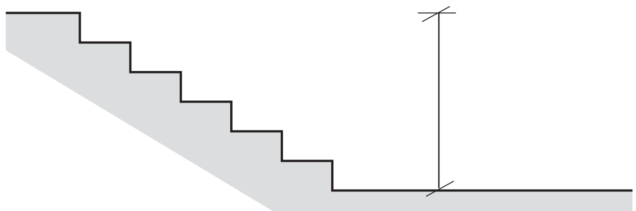

FIGURE A.5.3.5.3(2) Distance Measure for Walk Time Computation.

A.5.3.5.4 See A.5.3.4.1 for clarification.

A.5.3.5.6 Where multiple escalators are provided in the means of egress, the means of egress calculations should consider the potential of more than one escalator on any one level being out of service for repair and therefore impassible.

A.5.3.5.7(1) It is intended that escalators be as noncombustible as possible, with the understanding that certain components such as rollers or headrails might not currently be available in noncombustible materials. The authority having jurisdiction should review each installation proposal for compliance to the greatest extent possible.

A.5.3.5.7(2) The intent is to keep escalators running in the direction of egress in order to provide more efficient evacuation flow. Where escalators are an integral means of egress component in deep stations, the provision of emergency power for the escalators should be considered when supported by risk analysis.

A.5.3.5.7(4) Where required by accessibility regulations, visible message signs should be provided and designed to give pre-warning in accordance with the principles of this section.

A.5.3.6.2(2) Where a station has two elevators or fewer, this requirement should be interpreted as requiring that no elevators are counted as contributing to the available egress capacity.

A.5.3.6.2(3) Elevator capacity can be calculated as described in NIST IR 4730.

A.5.3.6.4(2) See B.4 of NFPA *101* and ASME A17.1/CSA B44 for additional guidance.

A.5.3.6.4(6) The design must also consider and provide for evacuation of other station levels.

A.5.3.6.4(7) Where supported by this analysis, the necessity for emergency recall should be considered.

A.5.3.7 For gates used as fare barriers, refer to 5.3.8. See Chapter 6 for requirements related to platform end gates.

A.5.3.7.1(2) The stated pedestrian capacity value assumes that the bi-parting doors and gates do not have mullions in the middle of the opening. The edge effect described in 5.3.4.2 need not be subtracted from the clear width. Where mullions are incorporated, the flow value for single-leaf doors should be used.

A.5.3.8.2 "Unimpeded travel in the direction of egress" means that any barriers in the equipment (such as paddles, gates, or turnstiles) either drop away to create a clear opening or swing or revolve freely in the direction of egress with no latching mechanism.

A.5.3.8.4(1) "Clear width" means the clear width between any protrusions with the fare gates open. The stipulated clear widths are appropriate where the length of the equipment console is less than 2500 mm in the egress direction. Where the equipment exceeds 2500 mm length, increased widths are recommended, which should be based on the anthropometric body sway data from NFPA *101*, as follows: Each unit should provide a minimum width of 560 mm (22 in.) clear width at and below a height of 1000 mm (39.5 in.) and 760 mm (30 in.) clear width above that height.

A.5.3.8.6 Refer to A.5.3.8.2.

A.5.3.9.1 Transit stations are unique in that many are constructed beneath and enveloped by adjacent buildings. The use of horizontal exits for up to 100 percent of the required capacity provided that not more than 50 percent is into a single building addresses conditions in stations that differ from those in NFPA *101*, which envisions a single building subdivision.

A.5.4.1 Where an underground station is part of another building complex, consideration should be given to creating a combined fire command center.

A.5.4.2.2 Discrete zone indications are desirable for unmanned stations.

A.5.4.2.6 Separate zones on the annunciator panel to monitor main control valves on standpipe systems should be established.

A.5.4.4.1 Escalators constructed of combustible stairs should be protected with an approved automatic sprinkler or fire suppression system installed in the truss area and designed to control or extinguish a fire.

A.5.4.5.1 The authority having jurisdiction might require additional 65 mm (2½ in.) hose connections to be equipped with a 65 mm × 40 mm (2½ × 1½ in.) reducer.

A.5.4.5.4 This requirement is intended to clarify that, with the approval of the local fire department, dry-type systems can be considered in stations regardless of the potential for freezing.

A.5.4.5.4(1) Calculations, including transit and fill times, should be submitted to the authority having jurisdiction to support this requirement.

A.6.1.1 The intent of the standard is to provide a reasonable level of life safety from fire and fire protection to passengers, transit system personnel, authorized visitors, and emergency responders. Generally, protective features such as egress routes in compliance with Chapter 6 are required for these areas, but see 6.4.6.2 for applicable ventilation requirements.

A.6.1.2.3 Locations requiring such signage may include, entrances to the trainway (e.g., station platforms and portals) and fences or barriers adjacent to the trainway.

A.6.2.1.6 See A.6.3.5.9.

A.6.2.2.1 Most tunnels exposed to prolonged fires are heavily damaged or collapse, resulting in service disruptions, significant structural damage, and most important, loss of lives (Both, Wolinsk & Breunese 2003, Khoury 2002, and Tatnall 2002). The structural concrete or shotcrete liner can be designed to withstand the fire load up to a certain period of time while accepting some minor repairable damage to the liner.

The fire resistance rating of the tunnel liners can be analyzed. Prompt operation of the ventilation system can mitigate damage to the liner.

A.6.2.4 The design of ancillary spaces adjacent to the trainway should be in accordance with the requirements of the local building codes except as specifically described in this standard. This would include requirements for egress from within the spaces and for heating, ventilation, and air-conditioning.

A.6.3.1.1 The trainway and the vehicle means of egress should be designed to be compatible. *(See Chapter 8.)*

A.6.3.1.4 Previous editions of NFPA 130 addressed this requirement by prescribing the maximum travel distance to an exit. The intent of this requirement was often misinterpreted. NFPA *101* requires, at a minimum, that two means of egress be provided within a building or structure and prescribes the maximum travel distance to an exit. This same requirement is applied in NFPA 130. Where two means of egress are required, the maximum travel distance to an exit occurs at the midpoint. For example, in a building with two exits, in the event of a fire adjacent to an exit rendering that exit unavailable, NFPA *101* recognizes that an individual in proximity to the affected exit must travel twice the prescribed exit travel distance to the alternative exit. Since two means of egress are required from any one point in an enclosed trainway, the exits cannot be more than twice the travel distance, or 762 m (2500 ft) apart.

A.6.3.1.6(2) The distance from the station should generally be measured to the end of the station platform. However, the distance can also be measured to an area of relative safety that is beyond the end of the platform, such as an exit stair or, where appropriate and based on evaluation of emergency ventilation airflow, a ventilation inlet.

A.6.3.1.6(7) The hazards to be considered include, but are not limited to, potential contact with live traction power distribution equipment.

A.6.3.2.1 Maintaining a clear space above the walking surface is important to ensure that projections do not encroach into the means of egress. The envelope created by the boundary limits defined by this paragraph is intended to gradually change from point to point. With respect to clearances to the vehicle, the measurements should be to the static vehicle envelope. *(See Figure A.6.3.2.1.)*

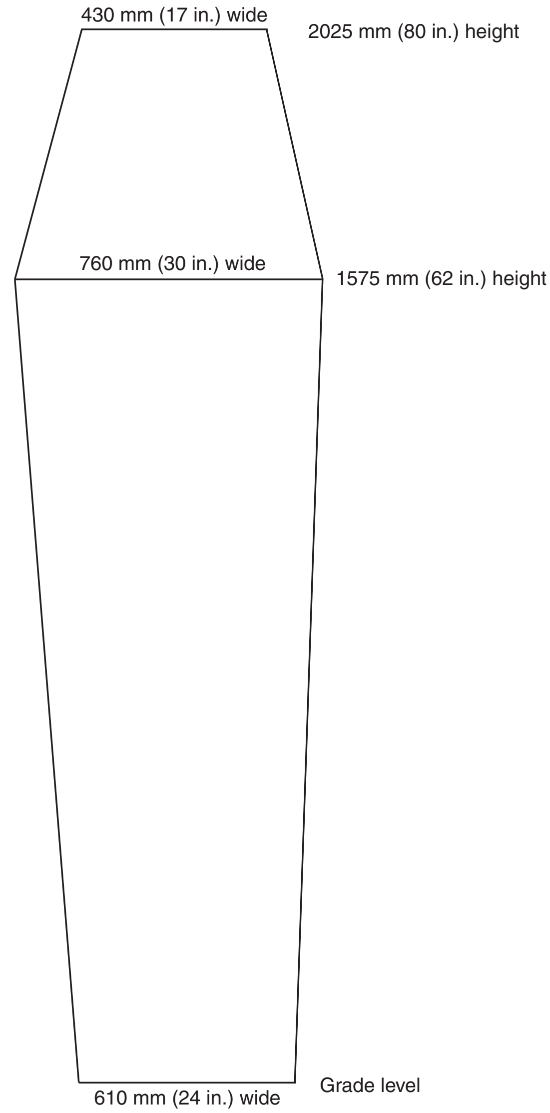

FIGURE A.6.3.2.1 Unobstructed Clear Width for Trainway Walkway.

A.6.3.2.3 With reference to NFPA *101*, Table 7.2.2.2.1.2(B) (where additional width is required for stairs serving an occupant load of 2000 people or more), exit stairs serving trainways are not required to exceed the minimum width, regardless of the occupant load. This is reasonable considering that evacuation flow from a tunnel would be essentially single file, and stairs do not normally converge with other egress routes.

A.6.3.2.4 The stipulated minimum width applies to all means of egress doorways, including those for cross-passages.

A.6.3.3 The egress provided should recognize that for multiple-track tunnels, there exists the possibility of having to evacuate simultaneously the incident train and a non-incident train(s) stranded on the adjacent track(s).

A.6.3.3.5 It is important that guards be configured so that they do not interfere with either the vehicle dynamic envelope or with egress from the train onto the walkway. For that reason, guards are not required on the trainway side of raised walkways, provided that the bottom of the trainway is closed by deck or grating so that persons could not fall through the bottom of the guideway.

A.6.3.3.8 It is important that handrails be configured so that they do not interfere with either the vehicle dynamic envelope or with egress from the train onto the walkway. For that reason, handrails are not required on the trainway side of raised walkways. Likewise, raised walkways located between trainways are not required to have handrails, provided they are a minimum width of 1120 mm (44 in.)

A.6.3.3.17 Where exit hatches are installed in spaces such as walkways or access areas, appropriate design features such as readily visible signs, markings, or bollards should be provided to prevent blockage of the exit hatch. In addition, provisions should be included in the design to protect the exterior side of the hatch, including the outside latch, from accumulation of ice and snow, which could render the hatch inoperable.

A.6.3.4.1 The primary hazards presented by the electrified third rail in the trainway are electrical shock to employees and other personnel in the trainway and the heat and smoke generated by the cable or third rail caused by combustion resulting from grounding or arcing.

The life safety and fire protection requirements for the traction power substations, tie breaker stations, and power distribution and control cabling are described in other parts of this standard.

A.6.3.5.9 This value is a minimum maintained point measured at any location on the walkway, taking into account the total light loss factor (dirt depreciation, lumen depreciation, etc.) that will be experienced by the luminaire. Required lighting levels should be read in the same manner as they would be in other codes or standards without consideration for obscuration by evacuees. The phrase "during a period of evacuation" is intended to clarify that continuous illumination is not required during normal operations.

A.6.3.5.11 Point illumination can be used to accentuate critical elements within the trainway such as change of walkway elevation, steps, and access points.

A.6.4.2.1 The placement of blue light stations at the ends of station platforms should be governed by specific characteristics of the transportation system and its emergency response procedures. For example, an at-grade system that has stations located on streets and overhead power supply might not need blue light stations at the ends of platforms.

A.6.4.4.2 The authority having jurisdiction might additionally require 65 mm (2½ in.) hose connections to be equipped with a 65 mm × 40 mm (2½ × 1½ in.) reducer.

A.6.4.4.4(1) Calculations, including transit and fill times, should be submitted to the authority having jurisdiction to support this requirement.

A.6.4.6.2 The intent of the standard is to provide a reasonable level of life safety for occupants. However, the risk faced in non-passenger areas where trains are merely stored or cleaned is significantly different from that in passenger areas (6.4.6.2 and 6.4.6.3 do not apply to maintenance and yards areas). This is because there are fewer ignition sources and fewer people, and the occupants will be either familiar with their surroundings (in the case of staff) or trained to react in hazardous locations (in the case of emergency responders). The standard continues to require ventilation and all other protective features, including compliant egress from these areas. Paragraphs 6.4.6.2 and 6.4.6.3 eliminate the requirement for the emergency ventilation system to meet the tenability criteria for other occupied areas. The standard permits tenability criteria in these areas to be reduced, provided that an engineering analysis shows that a fire in these areas will not impact areas occupied by passengers.

A.6.4.6.3 See A.6.4.6.2.

A.7.1.1 Separate ventilation systems for tunnels and underground stations can be provided but are not required. Annex B provides information on types of mechanical systems for normal and emergency ventilation of trainways and stations and information for determining a tenable environment.

A.7.1.2.2 Individual project geometries can impose constraints that make the length requirement of 7.1.2.2(2) onerous to meet. Proposals to the AHJ for relief based on engineering analysis might be made to address this. The following elements and performance goals should be considered in the development and justification of an alternative approach. A mechanical system intended for the purpose of emergency ventilation can be considered for waiver from an enclosed trainway if the length of the enclosed trainway is less than or equal to the length of that system's most prevalent train, provided that each vehicle within that most prevalent train permits a protected passenger egress route from each vehicle to the one (or two) adjoining vehicles. A rationale for selection and acceptance of the most prevalent train would be part of the justification. Conversely, a mechanical system intended for the purpose of emergency ventilation should not be waived in an enclosed trainway if the length of the enclosed trainway is equal to or greater than twice the NFPA recommendation *(see 6.2.2.2)* for the maximum distance that an evacuating passenger should have to travel before reaching an emergency exit stairway [381 m (1250 ft)]. The need for a mechanical system intended for the purpose of emergency ventilation should be analyzed further (as approved) if an enclosed trainway meets one of the following criteria:

(1) The length of the enclosed trainway is less than 762 m (2500 ft) but greater than that of the system's most prevalent train.
(2) The length of the enclosed trainway is less than that of the system's most prevalent train and each vehicle within that most prevalent train does not permit a protected passenger egress route from that vehicle to the one (or two) adjoining vehicle(s).

In the event that no analysis is performed or the justification is not approved, the default enclosed trainway design should include an emergency ventilation system.

A.7.2.1(3) The time frame required for achievement of the selected operating mode applies to the ventilation system equipment and not to the establishment of the resultant air flows in the tunnels and stations. This would be the time for the emergency ventilation system to achieve the required speed and direction for all related fans and to reach the required position for all dampers and related emergency devices.

A.7.2.5 Transition from fixed-block to moving-block (cab-based or communication-based) signaling is being made by many properties to increase train throughputs during rush hour operation. Ventilation zones are fixed elements, and the number of trains allowed in a single zone affects both ventilation plant requirements and the effectiveness of the ventilation response. Traction power blocks are fixed elements and affect the ability to extract non-incident trains from the incident ventilation zone. Signal system track circuits are fixed elements and affect the ability to determine the location of incident and non-incident trains in the incident ventilation zone. Signal system reversing capability and rapidness of executing a reversal in an emergency are key to the effective extraction of non-incident trains. Due to the potential for a valid incident ventilation response to move smoke past (and engulf) a non-incident train, the best protection to passengers is to allow no more than one train in a ventilation zone. Failing that, there should be a viable extraction capability to remove non-incident trains in the same time frame as the activation of the ventilation response. This extraction requires coordination of the three system elements in terms of design and operation. Non-incident trains should be capable of being located and removed from the incident area before the de-energization of the traction power prevents train movement for an extended period or the operation of the ventilation system in response to the fire incident involves the trains in the incident. Examples of the provisions necessary to accomplish this capability are the inclusion of traction power segmentation zones within ventilation zones and the inclusion of sufficiently short track signal circuit lengths to ensure all trains are accurately located.

A.7.2.6 The time of tenability should consider the possibility of one or more egress paths being blocked by fire or smoke (as may be demonstrated by analysis) and for other considerations that are not accounted for in the egress capacity calculations. *(See B.2.3 for additional information to be considered.)*

A.7.5.1 Factory approval acceptance testing prior to installation should be performed as follows:

(1) Ventilation equipment should comply with all the requirements of one of the applicable standards, which include those published by the Air Movement and Control Association International, the American Society of Heating, Refrigerating and Air-Conditioning Engineers, the International Organization for Standardization, and or UL (formerly, Underwriters Laboratories). If an appropriate standard does not exist, then a test procedure should be submitted for approval.
(2) Tests can consist of prototype testing or of production testing. Prototype testing should include those tests necessary to ensure that the design of the equipment is acceptable, including tests for design temperature exposure time. Production testing should include those tests necessary to ensure that the equipment as produced meets the requirements of the standard.

A.7.5.2 A test plan should be prepared and submitted to the owner and the AHJ for review and approval prior to the commissioning tests. The test plan should describe the method of testing and identify pass-fail criteria. As a minimum, the test plan should identify the following items:

(1) The commissioning tests should include individual equipment tests [as indicated in items (2) and (3)] and systemwide tests [as indicated in items (4) through (13)].
(2) The individual fans, dampers, and other devices should be operated to confirm their functionality. As a minimum, ventilation equipment operation should be initiated at the local primary location for fan operation such as an emergency management panel or fire management panel.
(3) The individual fan and ventilation plant airflows should be measured to confirm that the intended airflows are being delivered. At least one test should be made to measure the time required for the fan plant airflows to reach steady-state from a zero-flow start, and at least one test should be made to measure the time required for the fan plant airflows to reverse from full-forward to full-reverse operation. Subsequent tests should be conducted from Operations Central Control to verify remote fan and damper operation.
(4) The no-fire (or cold) station and tunnel airflows provided by the built mechanical ventilation system should be measured to confirm that the airflows meet the requirements determined by the analysis.
(5) The systemwide tests should be witnessed by the owner, the AHJ, the designer or the engineer of record, the contractor, and possibly the ventilation equipment suppliers.
(6) The systemwide testing should be done by a qualified airflow measurement specialist or contractor having previous experience in measuring airflows.
(7) Calibrated instruments providing an air velocity measurement accuracy of ±2.5 percent should be used. The number of points to be measured to convert air velocities to airflows should be determined either by the applicable standard used for the factory acceptance preinstallation testing (such as those published by the Air Movement and Control Association International, the American Society of Heating, Refrigerating and Air-Conditioning Engineers, the International Organization for Standardization or UL) or by a CFD analysis. The test data should be electronically recorded for future use.
(8) The fan(s) that are assumed to be operated and not operated by the analysis should be identified for each scenario being tested.
(9) At least one test should be performed to measure the time required for all the fans used in a fire scenario to reach full operating mode.
(10) The tunnel fire scenarios should be assessed and should include the design cases (i.e., those that determine the ventilation equipment functional capacities) and any other scenarios deemed appropriate. The train(s) should be located in the tunnel as per the scenario, and tunnel airflows upstream of the stopped trains should be measured. It is not necessary to test all scenarios.
(11) The station fire scenarios should be assessed and should include the design cases (i.e., those that determine the ventilation equipment's functional capacities) and any other scenarios deemed appropriate. The station geometry can preclude the necessity of locating trains in the station. Airflows through the station entrances and tunnels connected to the station should be measured. It is not necessary to test all scenarios.
(12) The airflows measured should be compared with the "cold flows" predicted by the analysis. If the measured airflows are less than the predicted airflows, the mechanical ventilation system or its operation should be changed and the test repeated until passing results are achieved. Negative tolerances in the results should not be accepted.
(13) The systemwide testing should be documented by one or more reports. The report should include a description of the scenario tested, the instrumentation used, the names and affiliations of those witnessing the tests, and all test results.

A.8.2 Federal Railroad Administration (FRA) requirements for passenger rail car and locomotive cab fire safety are contained in 49 CFR 238.

The requirements of 49 CFR 238, Section 103, are that interior materials be tested and meet certain flammability and smoke criteria and that floor fire endurance be tested. In addition, the requirements contain detailed fire safety analysis requirements for new equipment, to reduce the risk of personal injury and equipment damage caused by a fire to an acceptable level. The fire safety analysis requirements include the use of a formal safety methodology and written documentation of the analysis. In addition, the vehicle design and material selection are required to consider potential ignition sources; the type, quantity, and location of materials; and the availability of rapid and safe egress to the equipment exterior under conditions secure from fire, smoke, and other hazards. The ventilation system is required to not contribute to the lethality of a fire. Passenger railroads are also required to determine the extent to which overheat detection and fire suppression systems must be installed to ensure sufficient time for the safe evacuation of passengers and crew.

In addition to the specific fire safety requirements in 49 CFR 238, Section 103, other sections of the FRA requirements include fire safety–related provisions for passenger rail vehicles. Minimum requirements for fuel tanks for new passenger locomotives are intended to protect the fuel tanks against crushing and puncture in a collision or derailment. Requirements for passenger car electrical systems are also included. Conductor sizes must be selected on the basis of current carrying capacity, temperature, and other characteristics, and power dissipation resistors must be adequately ventilated to prevent overheating and be electrically insulated. The resistors and main battery system must be designed to prevent combustion. Such features can reduce the risk of fire ignition and spread in a collision or derailment and thus affect the necessity for and circumstances of emergency evacuation. Other CFR requirements are for passenger rail car and locomotive crashworthiness, as well as emergency exit and emergency responder access features. Annex E provides guidance relative to fire hazard assessments referenced in Section 8.3 through Section 8.10.

A.8.3.2 The purpose of this requirement is to isolate potential ignition sources from fuel and combustible material and to control fire and smoke propagation.

A.8.4.1 It is recommended that testing be conducted on production batches of materials intended to be used on the vehicle. A record of the performance of these materials should be retained by the authority.

It is recognized that the tests cited in 8.4.1 might not accurately predict the behavior of materials under hostile fire conditions. Therefore, the use of tests that evaluate materials in subassemblies and full-scale configurations is encouraged where such tests are more representative of foreseeable fire sources, heat flux levels, and surface area-to-volume ratios found in vehicles designed in conjunction with this standard.

The key fire property measured in the ASTM D 3675 and ASTM E 162 tests is the radiant panel index (or I_s).

A.8.4.1.1 ASTM E 162 might not be suitable for materials that exhibit flaming running or flaming dripping because the test apparatus is not designed to accommodate this kind of burning behavior. A fire hazard analysis seeking to demonstrate the acceptability of such materials as permitted in 8.4.2 should include not only the contribution to the generation of heat and smoke at the original ignition site but also any contribution resulting from burning material that melts and/or flows away from that site. The fire hazard analysis also should address the risk of spread to and ignition of other car components from either of these potential ignition sources.

A.8.4.1.3 The test methods in ASTM E 1537 [for upholstered furniture, 19 kW/(65 KBtu/hr) exposure] and ASTM E 1590 [for mattresses, 18 kW/(61 KBtu/hr) exposure] are deemed to be adequate procedures for testing individual items of upholstered furniture or mattresses for purposes of fire hazard assessment in some public occupancies. However, such individual stand-alone (not fixed in place) items are not normally found in rail transportation vehicles. Thus, the applicability of the test methods to rail transportation vehicles has not been validated, and they probably are not sufficiently representative of the situation and might require some modifications for better applicability. The use of alternative ignition sources (by varying the location, the gas flow intensity, or the exposure time) for ASTM E 1537 or ASTM E 1590 might be a means of addressing some very high challenge fire scenarios that could potentially occur in rail transportation vehicles. Examples of more powerful ignition sources that could be used include a 50 kW gas burner [Hirschler, 1997], shown to be relevant to detention mattresses or the oil burner used for aircraft seat cushions [FAR 25.853(c)], but the measurements should involve the same fire properties as in ASTM E 1537 or ASTM E 1590. If the ignition source used for a test method is inadequate, the result can be misleading; it has been shown that upholstered furniture and mattresses that are totally consumed when using the appropriate ignition source appear to perform well when using the ignition sources in ASTM E 1537 and ASTM E 1590, respectively.

A.8.4.1.10 If the surface area of any individual small part is less than 100 cm^2 (16 in.^{2}) in end use configuration, materials used to fabricate such a part should be permitted to be tested in accordance with ASTM E 1354 as an alternative to both the ASTM E 162 flammability test procedure or the appropriate flammability test procedure otherwise specified in Table 8.4.1 and the ASTM E 662 smoke generation test procedure. Testing should be at 50 kW/m^2 (4.4 Btu/sec·ft^2) applied heat flux in the horizontal orientation with a retainer frame. Materials tested in accordance with ASTM E 1354 should meet the performance criteria of a 180-second average heat release rate of q''_{180} < 100 kW/m^2 (8.8 Btu/sec·ft^2) and test average smoke extinction area of (F_f) < 500 m^2/kg (2441.2 ft^2/lb).

The typical way in which smoke obscuration test results are reported in the cone calorimeter (ASTM E 1354) is as specific extinction area.

A.8.4.1.14 Only one specimen need be tested. A proportional reduction can be made in the dimensions of the specimen, provided the specimen represents a true test of the ability of the structural flooring assembly to perform as a barrier against undervehicle fires.

A.8.4.1.15 ASTM E 2061 and APTA RP PS-005-01a both describe and discuss passenger-carrying vehicle fire scenarios. *(See also Annex E.)*

A.8.4.2 The greater the anticipated effect of the material on fire performance, the more complex the analysis is likely to be.

A.8.5.1.3.2(1) Computer models typically utilize passenger-carrying vehicle fire heat release rate data to predict the size of a vehicle fire that will occur after an interior fire reaches flashover. Vehicle interior fire computer models assume either that a fire is started on the inside of a vehicle or that an undercar fire penetrates into the vehicle interior, igniting any combustible material in the area of penetration. Typically, a floor fire resistance test is conducted only for the approved length of time. Consideration should be given to extending the floor fire exposure until failure. If a test is conducted until failure, it will give designers a better idea as to the length of time it will take for a fire to penetrate into a vehicle and ignite any combustible materials on the vehicle interior.

A.8.5.1.3.2(2) For determination of the minimum floor exposure time, the operating environment should be considered in addition to the time necessary to evacuate passengers from the vehicle. Typical issues that should be considered are the time necessary to shut down power to the affected portion of the trainway, distance to a cross-passageway, distance to an emergency exit, and availability of adequate light to perform a safe evacuation.

A.8.5.1.3.3(2) Since smoke generation is a factor that has a direct effect on a passenger's ability to evacuate a vehicle, observations should be noted during the length of the floor fire exposure as to the origin and quantity of smoke generated from the fire test sample. These observations should be recorded in the fire test report.

A.8.6.2.2 In selecting air clearance distances, special consideration should be given to the presence of contaminants encroaching on the air clearances.

A.8.6.2.3.2 Appropriate creepage distances can be selected from Annex F.

A.8.6.5.1 Resistors dissipate heat at elevated temperatures and are frequently separated by noncombustible shields to avoid ignition of combustible train materials. Direct contact with combustibles is a fire hazard and minimum spacing should be established if combustible materials are required to be used. The clear spacing will vary depending on location, orientation, and fire characteristics of the combustible train materials.

A.8.6.7.1.3 The electrical properties of data and communication cables should comply with requirements for category cable or local electrical requirements. Different system authorities specify data and communication cables that have specific electrical requirement other than voltage.

A.8.8.1 Since 1980, the Federal Railroad Administration (FRA) has required that each rail passenger car be provided with at least four emergency window exits. In 1999, the FRA issued a passenger equipment rule that required each intercity and commuter rail car to be equipped with a minimum number of two side doors per car and at least four emergency window exits for each main level. Each sleeping compartment must also be provided with an emergency window exit. Because fixed guideway vehicles historically have been provided with at least two sets of bi-leaf side doors, one on each side, emergency exit windows usually are not provided.

A.8.8.1.1 After a collision or derailment, the vehicle might come to a rest in an orientation other than upright. When designing alternative means of emergency egress, consideration should be given to reaching the emergency egress, regardless of vehicle orientation. This can be accomplished by the utilization of fixed appurtenances in the vehicle, ladders, or ramps.

A.8.8.3.1 The level of emergency lighting illumination was previously required to meet the requirements of NFPA *101*. However, research conducted by the John A. Volpe Transportation Systems Center (Volpe Center) for the Federal Railroad Administration (FRA), U.S. Department of Transportation, determined that the level of illumination required by NFPA *101* might not be necessary due to the more limited size [25.9 m (85 ft) long and 3.1 m (10 ft) wide)] and configuration of passenger rail vehicles (and by extension, fixed guideway transit vehicles). The Volpe Center performed numerous detailed measurements of illumination levels provided by emergency light facilities installed on many types and ages of intercity and commuter rail vehicles. The majority of fixed guideway transit and passenger rail vehicle emergency lighting systems use fluorescent light fixtures. However, some systems used incandescent fixtures. While the fluorescent light fixtures typically emit higher levels of illumination and are thus preferred, some incandescent light fixtures (depending on their type, power output and location, and pattern) also provide sufficient illumination to allow passengers to identify, reach, and operate emergency egress facilities.

The Federal Aviation Administration (FAA) has conducted many research studies relating to emergency lighting illumination levels for passenger aircraft. The FAA requires different illumination levels at floor level doors and emergency window locations and along the center aisle. The center aisle illumination levels are measured at the armrest height. Due to the different armrest heights exhibited by passenger rail vehicles, the Volpe Center research resulted in the recommendation for a uniform height of 635 mm (25 in.) above the floor height to perform the aisle measurements.

Accordingly, the FRA issued a passenger equipment regulation on May 12, 1999, that specified the Volpe-recommended minimum illumination level for egress door floor locations, minimum illumination average along the center aisle, and a minimum illumination at any point along the aisle for new equipment.

Moreover, the American Public Transportation Association (APTA) standard APTA SS-E-013 addresses passenger rail vehicle emergency lighting. The APTA standard requires minimum emergency lighting levels for new intercity passenger and commuter rail vehicles that are identical to FRA requirements and contains additional guidance in performing the illumination measurements. The APTA emergency lighting standard was updated in 2007 to provide a detailed test methodology. The APTA standard provides guidance that could be applied to fixed guideway transit vehicles.

A.8.8.3.3 Depending on the location of the train, the time necessary to initiate and complete the evacuation of passengers from the fixed guideway transit or passenger rail vehicle to a point of safety can exceed 1 hour. The minimum period of time for the vehicle emergency lighting system power supply is consistent with NFPA *101*, APTA SS-E-013, and the FRA regulation.

A.8.8.4 Until the 2003 edition, NFPA 130 did not address the manual operation of emergency egress (or access) facilities for the vehicle interior or exterior, the interior and exterior marking of the egress/access facility location, or instructions for the use of the emergency egress/access facilities. Several emergency incidents occurred that demonstrated the necessity of providing passengers with a means to manually operate, without tools, means of emergency egress in the event of a power failure. Operational issues to be considered include the need to discourage use under nonemergency conditions while permitting effective passenger use in an emergency, particularly if members of the train crew are injured or otherwise unavailable.

• **A.8.8.5** The FAA requires the installation of independently powered floor proximity path marking to delineate the path to emergency exits. APTA also has issued a standard that requires this same concept of marking to be installed in intercity and commuter rail cars.

The FRA issued a rule in 1998 that required marking and instructions for the operation of emergency exit windows and doors used for emergency egress. Although the FRA requires that the marking be conspicuous and legible, specific objective performance criteria were not included.

APTA has issued a standard that contains extensive provisions for the marking of and instructions for emergency egress facilities that are operated from inside the vehicle. These minimum performance criteria include letter height, color contrast, and luminance levels.

The APTA standard requires that marking and instructions use either electrically powered or high-performance photo luminescent (HPPL) material. The HPPL material must be charged with adequate light [54 lx (5 ft-candles) for at least 1 hour] but offers the advantage of providing a far greater luminance (brightness) over a far longer time period while not being dependent on emergency power. HPPL material has been certified by the FAA for use as floor proximity path marking on certain aircraft.

A.8.11.1 Annex D provides additional information on the fire hazards associated with burning vehicles and the impact of a burning vehicle on the evacuation of passengers and crew.

A.8.11.2 Section 4.3 includes specific objectives necessary to achieve desired goals. Further guidance relative to the engineering analysis option for compliance could include explanatory material regarding performance-based compliance in other documents, such as NFPA *101.*

A.9.2.4 The following standards might be applicable for training qualification and competency assessment: NFPA 1006, NFPA 472, and NFPA 1670.

A.9.4 Tunnels more than 610 m (2000 ft) in length should be equipped with emergency tunnel evacuation carts (ETECs) at locations to be determined by the authority having jurisdiction.

ETECs should be capable of carrying a capacity of at least four stretchers and a total weight capacity of at least 453.5 kg (1000 lb). ETECs should be constructed of corrosion-resistant materials, be equipped with a "deadman" brake, and safely operate on the rail tracks in the tunnel.

A.9.5 The agencies and their names might vary depending on the governmental structure and laws of the community.

A.9.6.9 Fan units serving train control and communications rooms should be protected by fire detection, protection, and extinguishing equipment so that there will be early detection and extinguishment of any fire involving these units.

A.9.8.1 The command post should be located at a site that is convenient for responding personnel, easily identifiable, and suitable for supervising, coordinating, and communicating with participating agencies.

A.9.8.5 Signs should be designed to be visible day and night and under bad weather conditions.

A.9.9 Any emergency response agency can establish an auxiliary command post to assist with the supervision and coordination of personnel and equipment. This activity is in addition to providing a liaison at the command post.

A.10.1 Comprehensive and dependable communications are essential for an effective and efficiently operated fixed guideway transit system during emergencies.

A.11.2.1 It is desirable that passengers are evacuated directly to a station platform, rather than to a trainway, to avoid the complications of a trainway evacuation.

A.11.3.1 Different situations that can render a system unavailable include data overloads, both intentional or unintentional; loss of data; loss of a control room due to fire; loss of battery power; and circuits shorted or open.

A.11.3.2 Single points of failure that will affect life safety during fires and the mitigation of those single points of failure should be considered during conceptualization.

A.11.3.3 When it is essential that a control, data, or communication system continue to function during a fire, both thermal and physical protection are likely to be required, since a fire resistance–rated element intended to protect the control, data, or communication system might not offer the expected thermal protection to the unexposed side for the duration of the fire resistance rating.

A.12.1.2 The life safety and fire protection requirements for the traction power substations, the breaker station's power distribution, and control cabling are described in other parts of this standard.

A.12.5.3 When selecting a fire-resistive cable, it is important to understand how it will be installed and if it was tested as a complete system, including splices. Cables that are exposed (not embedded in concrete) should be protected by either a raceway or an armor/sheath *(see 12.4.1)*. There are two basic configurations of fire-resistive cables. Cables enclosed by a metallic sheath or armor, such as Type MI or Type MC, are installed without raceways. Cables that are installed in a raceway, such as Type RHW-2, Type TC, or Type CM are tested as a complete system. Regardless of the fire test standard used to evaluate fire-resistive cables that will be installed in a raceway, it is important to consider that the cables are only one part of the system. Other components of the system include but are not limited to: the type of raceway, the size of raceway, raceway support, raceway couplings, boxes, conduit bodies, splices where used, vertical supports, grounds, and pulling lubricants. Each cable type should be tested to demonstrate compatibility. Only those specific types of raceways tested should be acceptable for installation. Each cable type that is intended to be installed in a raceway should be tested in both a horizontal and vertical configuration while demonstrating circuit integrity.

Annex B Ventilation

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

B.1 General. The purpose of this annex is to provide guidelines for the potential compatibility of the emergency ventilation system with the system employed with normal ventilation of trainways and stations. This annex does not present all factors to be considered in the normal ventilation criteria. For normal ventilation, refer to the *Subway Environmental Design Handbook* (*SEDH*) and the ASHRAE handbooks *Fundamentals*, *Applications*, and *Systems and Equipment*.

Current technology is capable of analyzing and evaluating all unique conditions of each property to provide proper ventilation for normal operating conditions and for pre-identified emergency conditions. The same ventilating devices might or might not serve both normal operating conditions and pre-identified emergency requirements. The goals of the subway ventilation system, in addition to addressing fire and smoke emergencies, are to assist in the containment and purging of hazardous gases and aerosols such as those that could result from a chemical/biological release.

B.2 Tenable Environments.

B.2.1 Environmental Conditions. Some factors that should be considered in maintaining a tenable environment for periods of short duration are defined in B.2.1.1 through B.2.1.5.

B.2.1.1 Heat Effects. *(See also H.1.2.11.)* Exposure to heat can lead to life threat in three basic ways:

(1) Hyperthermia
(2) Body surface burns
(3) Respiratory tract burns

For use in the modeling of life threat due to heat exposure in fires, it is necessary to consider only two criteria: the threshold of burning of the skin and the exposure at which hyperthermia is sufficient to cause mental deterioration and thereby threaten survival.

Note that thermal burns to the respiratory tract from inhalation of air containing less than 10 percent by volume of water vapor do not occur in the absence of burns to the skin or the face; thus, tenability limits with regard to skin burns normally are lower than for burns to the respiratory tract. However, thermal burns to the respiratory tract can occur upon inhalation of air above 60°C (140°F) that is saturated with water vapor.

The tenability limit for exposure of skin to radiant heat is approximately 2.5 kW·m^{-2}. Below this incident heat flux level, exposure can be tolerated for 30 minutes or longer without significantly affecting the time available for escape. Above this threshold value, the time to burning of skin due to radiant heat decreases rapidly according to Equation B.2.1.1a.

$$t_{Irad} = 106q^{-1.35} \qquad \textbf{(B.2.1.1a)}$$

where:
t = time in minutes
q = radiant heat flux (kW/m^2)

As with toxic gases, an exposed occupant can be considered to accumulate a dose of radiant heat over a period of time. The fraction equivalent dose (FED) of radiant heat accumulated per minute is the reciprocal of t_{Irad}.

Radiant heat tends to be directional, producing localized heating of particular areas of skin even though the air temperature in contact with other parts of the body might be relatively low. Skin temperature depends on the balance between the rate of heat applied to the skin surface and the removal of heat subcutaneously by the blood. Thus, there is a threshold radiant flux below which significant heating of the skin is prevented but above which rapid heating occurs.

Based on the preceding information, it is estimated that the uncertainty associated with the use of Equation B.2.1.1a is ±25 percent. Moreover, an irradiance of 2.5 kW·m^{-2} would correspond to a source surface temperature of approximately 200°C, which is most likely to be exceeded near the fire, where conditions are changing rapidly.

Calculation of the time to incapacitation under conditions of exposure to convected heat from air containing less than 10 percent by volume of water vapor can be made using either Equation B.2.1.1b or Equation B.2.1.1c.

As with toxic gases, an exposed occupant can be considered to accumulate a dose of convected heat over a period of time. The fraction equivalent dose (FED) of convected heat accumulated per minute is the reciprocal of t_{Iconv}.

Convected heat accumulated per minute depends on the extent to which an exposed occupant is clothed and the nature of the clothing. For fully clothed subjects, Equation B.2.1.1b is suggested:

$$t_{Iconv} = \left(4.1\times10^{8}\right)\ T^{-3.61} \qquad \textbf{(B.2.1.1b)}$$

where:
t_{Iconv} = time in minutes
T = temperature (°C)

For unclothed or lightly clothed subjects, it might be more appropriate to use Equation B.2.1.1c:

$$t_{Iconv} = \left(5\times10^{7}\right)\ T^{-3.4} \qquad \textbf{(B.2.1.1c)}$$

where:
t_{Iconv} = time in minutes
T = temperature (°C)

Equations B.2.1.1b and B.2.1.1c are empirical fits to human data. It is estimated that the uncertainty is ±25 percent.

Thermal tolerance data for unprotected human skin suggest a limit of about 120°C (248°F) for convected heat, above which there is, within minutes, onset of considerable pain along with the production of burns. Depending on the length of exposure, convective heat below this temperature can also cause hyperthermia.

The body of an exposed occupant can be regarded as acquiring a "dose" of heat over a period of time. A short exposure to a high radiant heat flux or temperature generally is less tolerable than a longer exposure to a lower temperature or heat flux. A methodology based on additive FEDs similar to that used with toxic gases can be applied. Provided that the temperature in the fire is stable or increasing, the total fractional effective dose of heat acquired during an exposure can be calculated using Equation B.2.1.1d:

$$FED = \sum_{t_1}^{t_2}\left(\frac{1}{t_{Irad}}+\frac{1}{t_{Iconv}}\right)\Delta t \qquad \textbf{(B.2.1.1d)}$$

Note 1: In areas within an occupancy where the radiant flux to the skin is under 2.5 kW · m^{-2}, the first term in Equation B.2.1.1d is to be set at zero.

Note 2: The uncertainty associated with the use of this last equation would be dependent on the uncertainties with the use of the three earlier equations.

The time at which the FED accumulated sum exceeds an incapacitating threshold value of 0.3 represents the time available for escape for the chosen radiant and convective heat exposures.

As an example, consider the following:

(1) Evacuees lightly clothed
(2) Zero radiant heat flux
(3) Time to FED reduced by 25 percent to allow for uncertainty in Equations B.2.1.1b and B.2.1.1c.
(4) Exposure temperature constant
(5) FED not to exceed 0.3

Equations B.2.1.1c and B.2.1.1d can be manipulated to provide:

$$t_{exp} = \left(1.125\times10^{7}\right)T^{-3.4}$$

where:
t_{exp} = time of exposure (min.) to reach a FED of 0.3

This gives the values in Table B.2.1.1.

Table B.2.1.1 Maximum Exposure Time

Exposure Temperature °C	Exposure Temperature °F	Without Incapacitation (min.)
80	176	3.8
75	167	4.7
70	158	6.0
65	149	7.7
60	140	10.1
55	131	13.6
50	122	18.8
45	113	26.9
40	104	40.2

B.2.1.2 Air Carbon Monoxide Content. An exposed occupant can be considered to accumulate a dose of carbon monoxide over a period of time. This exposure to carbon monoxide can be expressed as a fractional effective dose, according to Equation B.2.1.2a; see B.2.1.2.1, reference [1] [page 6, equation (2)]:

$$FED_{CO} = \sum_{t_1}^{t_2} \frac{[CO]}{35000} \Delta t$$

where:

Δt = time increment in minutes

$[CO]$ = average concentration of CO (ppm) over the time increment Δt

It has been estimated that the uncertainty associated with the use of Equation B.2.1.2a is ±35 percent. The time at which the FED accumulated sum exceeds a chosen incapacitating threshold value represents the time available for escape for the chosen carbon monoxide exposure. As an example, consider the following:

(1) Time to FED reduced by 35 percent to allow for the uncertainty in Equation B.2.1.2a
(2) Exposure concentration constant

This gives the values in Table B.2.1.2 for a range of threshold values.

Table B.2.1.2 Maximum Carbon Monoxide Exposure

Time (min)	Tenability Limit AEGL 2	0.3	0.5
4	–	1706	2844
6	–	1138	1896
10	420	683	1138
15	–	455	758
30	150	228	379
60	83	114	190
240	33	28	47

A value for the FED threshold limit of 0.5 is typical of healthy adult populations [1], 0.3 is typical in order to provide for escape by the more sensitive populations [1], and the AEGL 2 limits are intended to protect the general population, including susceptible individuals, from irreversible or other serious long-lasting health effects [2].

The selection of the FED threshold limit value should be chosen appropriate for the fire safety design objectives. A value of 0.3 is typical. More conservative criteria may be employed for use by especially susceptible populations. Additional information is available in references [1] and [3].

B.2.1.2.1 The following references are cited in B.2.1.2:

(3) Kuligowski, E. D., "Compilation of Data on the Sublethal Effects of Fire Effluent," Technical Note 1644, National Institute of Standards and Technology, 2009.

B.2.1.3 Smoke Obscuration Levels. Smoke obscuration levels should be maintained below the point at which a sign internally illuminated at 80 lx (7.5 ft-candles) is discernible at 30 m (100 ft) and doors and walls are discernible at 10 m (33 ft).

B.2.1.4 Air Velocities.

B.2.1.4.1 Air velocities in enclosed stations and trainways should be greater than or equal to 0.75 m/sec (150 fpm).

B.2.1.4.2 Air velocities in enclosed stations and trainways that are being used for emergency evacuation or by emergency personnel should not be greater than 11.0 m/sec (2200 fpm).

B.2.1.5 Noise Levels. Noise levels should be a maximum of 115 dBa for a few seconds and a maximum of 92 dBa for the remainder of the exposure.

B.2.2 Geometric Considerations. Some factors that should be considered in establishing a tenable environment in stations are as follows:

(1) The evacuation path requires a height clear of smoke of at least 2 m (6.6 ft). For low-ceiling areas, selection of the modeling method and the criteria to be achieved should address the limitations imposed by ceiling heights below 3 m (9.84 ft). At low-ceiling areas in an evacuation path, beyond the immediate vicinity of a fire, smoke should be excluded to the greatest extent practicable.
(2) The application of tenability criteria at the perimeter of a fire is impractical. The zone of tenability should be defined to apply outside a boundary away from the perimeter of the fire. This distance will be dependent on the fire heat release rate, the fire smoke release rate, local geometry, and ventilation and could be as much as 30 m (100 ft). A critical consideration in determining this distance will be how the resultant radiation exposures and smoke layer temperatures affect egress. This consideration should include the specific geometries of each application, such as vehicle length, fire location, platform width and configuration, and ventilation system effectiveness, among others, and how those factors interact to support or interfere with access to the means of egress.
(3) The beneficial effects of an emergency ventilation system during a fire incident will not become completely available until the system is operated and reaches full capacity. During the time between initiation of a fire incident and the desired ventilation response achieving its full capacity, the smoke can spread into the intended zone of tenability. The ventilation system should have sufficient capacity to counter this

pre-ventilation smoke spread. Whenever possible, the design of the space geometry should consider arrangements to minimize the pre-ventilation smoke spread. The overall extent of pre-ventilation smoke spread should also be considered with respect to its potential effect on egress.

(4) During the emergency ventilation response, short-term transient events due to step-like changes in geometry can momentarily provide a significant boost to the fire heat and smoke release rates. Examples include vehicle doors opening or the failure of vehicle windows. The ventilation system should have sufficient capacity to counter such short-term transients affecting smoke spread.

B.2.3 Time Considerations. Some factors that should be considered in establishing the time of tenability are as follows:

(1) The time for fire to ignite and become established
(2) The time for fire to be noticed and reported
(3) The time for the entity receiving the fire report to confirm existence of fire and initiate response
(4) The time for all people who can self-rescue to evacuate to a point of safety
(5) The time for emergency personnel to arrive at the station platform
(6) The time for emergency personnel to search for, locate, and evacuate all those who cannot self-rescue
(7) The time for fire fighters to begin to suppress the fire

B.2.4 Modeling Accuracy. Where modeling is used to determine factors such as temperature, visibility, and smoke layer height, an appropriate sensitivity analysis should be performed.

B.3 Configurations. Configurations can vary among properties, but engineering principles remain constant. The application of those principles should reflect the unique geometries and characteristics of each property.

Enclosed stations and trainways might be configured with the following characteristics:

(1) High or low ceilings
(2) Open or doored entrances
(3) Open or screened platform edges
(4) End-of-station or midtunnel fan shafts
(5) End-of-station or midtunnel vent shafts
(6) Single, double, or varying combinations of tracks in tunnels
(7) Intersecting tunnels
(8) Multilevel stations
(9) Multilevel tunnels
(10) Varying depths below the surface
(11) Varying grades and curvatures of tracks and tunnels
(12) Varying blockage ratios of vehicles to tunnel cross-section
(13) Varying surface ambient conditions
(14) Varying exit points to surface or points of safety

B.4 Draft Control.

B.4.1 For patron comfort in stations, the air velocities induced by train motion should be evaluated carefully by designers. Infrequent exposure to higher velocities can be tolerated briefly but are to be avoided wherever possible. Refer to the *Subway Environmental Design Handbook* (*SEDH*), the *ASHRAE Handbook — Fundamentals,* and the *Beaufort Scale.*

B.4.2 Draft control can be achieved by the placement of shafts along the tunnel length between stations. Shafts can be arranged with the fan shafts at the ends of stations, with vent shafts midtunnel if required or with vent shafts at the ends of stations and fan shafts midtunnel. End-of-station shaft configurations should be related to the station geometries in the consideration of patron comfort in the station relative to train piston draft effects.

B.5 Temperature Control.

B.5.1 Temperature control for patron comfort in the station can be achieved by circulating ambient air in moderate climates or by providing heating and/or cooling in more extreme regions. Preferred temperature goals should be defined in the criteria developed for the design of an individual property relative to the local climate and the length of station occupancy, such as train headways specific to the property during which the patron would be exposed to the station temperatures.

B.5.2 Temperature control and ventilation for ancillary areas housing special equipment should reflect the optimum operating conditions for the specific equipment to ensure the availability of critical equipment and should also give consideration for intermittent occupancy by maintenance personnel. These systems should be separate from the emergency ventilation system for stations and tunnels and should be considered in the design of the emergency ventilation system.

B.6 Under-Platform Ventilation System.

B.6.1 An under-platform ventilation system should be considered for the extraction of heat from traction and braking devices. Intakes should be provided below the platform level and should be situated relative to the heat-producing devices on a train berthed in a station.

B.6.2 Ceiling ventilation, by powered or gravity design, to aid in the removal of smoke and/or heat should be considered.

B.7 Platform Edge and Screen Doors.

B.7.1 Platform edge doors and platform screen doors are sometimes incorporated into stations for various reasons, such as climate control, separation between passengers and trainway hazards (especially in driverless systems), and ventilation control in enclosed trainways. When used, these system walls and doors should provide resistance rating structural strength relative to the train and ventilation system pressures.

B.7.2 In a tunnel-to-station evacuation scenario, access to the platform level from the trainway should be considered.

B.8 Non-Emergency Ventilation for Enclosed Trainways.

B.8.1 Congested Operations. Where trains might be stopped or delayed in an enclosed trainway for a period of time, the vehicle ventilation system should be capable of maintaining an acceptable level of patron comfort. If not operating in a fire or other emergency scenario, the emergency ventilation fans can be used to augment the vehicle system capability.

B.8.2 Maintenance Activities. Maintenance activities within station and tunnel areas can include heat-, dust-, or fume-producing operations such as grinding, welding, or painting; operation of fuel-powered vehicles or equipment; and other operations that affect tunnel air quality or temperature. If not operating in a fire or other emergency scenario, the tunnel ventilation fans can be used to address the safety and comfort of employees working in the affected tunnel and station areas. In such cases, velocities should consider the comfort levels of employees required to be in the tunnels.

B.8.3 Tunnels in Gassy Ground. Tunnels in gassy ground could be subject to ingress of flammable or other hazardous gases. Gases of concern include hydrogen sulfide (H_2S) and methane (CH_4). The ventilation system should be designed to satisfy two objectives:

(1) To avoid pockets of gases forming
(2) To achieve dilution of gas inflows through a design crack

The ventilation design should be coordinated with the gas detection and alarm system type and the activation levels selected. The design should consider two general conditions:

(1) Ongoing or periodic ventilation requirements to meet expected average gas ingress rates
(2) Reaction to potential abrupt increases in gas ingress, such as might result from future construction, climate events, or seismic activity

Annex C Means of Egress Calculations for Stations

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

C.1 Station Occupant Load. The station platform dimensions are a function of the length of trains served and the train load. Thus the length of a platform at an outlying station might be equal to those of central business district transit stations where the train loads are significantly higher. Consequently, the platform and station occupant loads are a function of the train load and the simultaneous entraining load. This concept differs from that of NFPA *101*, in which the occupant load is determined by dividing the floor area by an occupant load factor assigned to that use. Applying the NFPA *101* approach to determine the station platform occupant load is inappropriate.

C.1.1 Calculating Occupant Load. Projected ridership figures serve as the basis for determining transit system design. Per this standard, the methodology used to determine ridership figures must also include peak ridership figures for new transit systems and existing operating systems. Events at stations such as civic centers, sports complexes, and convention centers that establish occupant loads not included in normal passenger loads must also be included. These ridership figures serve as the basis for calculating train and entraining loads and the station occupant load. The methodology used for determining passenger ridership figures can vary by transit system. The use of statistical methods for determining *calculated train loads* and *calculated entraining loads* will provide a more accurate indication of the required means of egress facilities within a station.

C.1.2 Calculating Evacuation Time. The total evacuation time is the sum of the walking travel time for the longest exit route plus the waiting times at the various circulation elements. The trainway can be considered as an auxiliary exit from the station under certain fire scenarios.

The waiting time at each of the various circulation elements is calculated as follows:

(1) For the platform exits, by subtracting the walking travel time on the platform from the platform exits flow time
(2) For each of the remaining circulation elements, by subtracting the maximum of all previous element flow times

The symbols used in the sample calculations in this annex represent the walking times, flow times, and waiting times as follows:

T = total walking travel time for the longest exit route

T_p = walking travel time on the platform

T_X = walking travel time for the Xth segment of the exit route

F_p = platform exits flow time

F_{fb} = fare barrier flow time

F_c = concourse exits flow time

F_N = flow time for any additional circulation element

$W_p = F_p - T_p$ = waiting time at platform exits

$W_{fb} = F_{fb} - F_p$ = waiting time at fare barriers

$W_c = F_c - \max(F_p \text{ or } F_{fb})$ = waiting time at concourse exits

$W_N = F_N - \max(F_c, F_{fb}, \text{ or } F_p)$ = waiting time at any additional circulation element

Note that the waiting time at any circulation element cannot be less than zero.

C.1.3 Center-Platform Station Sample Calculation. The sample center-platform station is an elevated station with the platform above the concourse, which is at grade *(see Figure C.1.3)*. The platform is 183 m (600 ft) long to accommodate the train length. The vertical distance from the platform to the concourse is 9.1 m (30 ft).

The sample station has one paid area separated from the outside by a fare array containing four electronic fare gates and one 1220 mm (48 in.) handicapped/service gate. In addition, two 1830 mm (72 in.) wide emergency exits are provided. Six open wells communicate between the platform and the concourse. Each well contains one stair or one escalator. Station ancillary spaces are located at the concourse level.

Elevators (not shown in Figure C.1.3) are provided for use by handicapped persons or service personnel. Open emergency stairs are provided at each end of the platform and discharge directly to grade through grille doors with panic hardware.

Escalators are nominal 1220 mm (48 in.) wide. Stairs regularly used by patrons are 1830 mm (72 in.) wide, and emergency stairs are 1220 mm (48 in.) wide. Gates to emergency stairs are 1220 mm (48 in.) wide.

The station occupant load is 2314 persons.

Table C.1.3 lists the data for the exiting analysis of the sample center-platform station.

Test No. 1. Evacuate platform occupant load(s) from platform(s) in 4 minutes or less.

$$F_p \text{ (time to clear platform)} = \frac{\text{Platform occupant load}}{\text{Platform exit capacity}}$$

$$F_p = \frac{2314}{609}$$

$$F_p = 3.80 \text{ minutes}$$

In Test No. 1, the time to clear the platform is found to be 3.80 minutes. This meets the requirement of 5.3.3.1.

Test No. 2. Evacuate platform occupant load from most remote point on platform to a point of safety in 6 minutes or less.

W_p (waiting time at platform exits) $= F_p - T_1$

$W_p = 3.80 - 1.09 = 2.71$ minutes

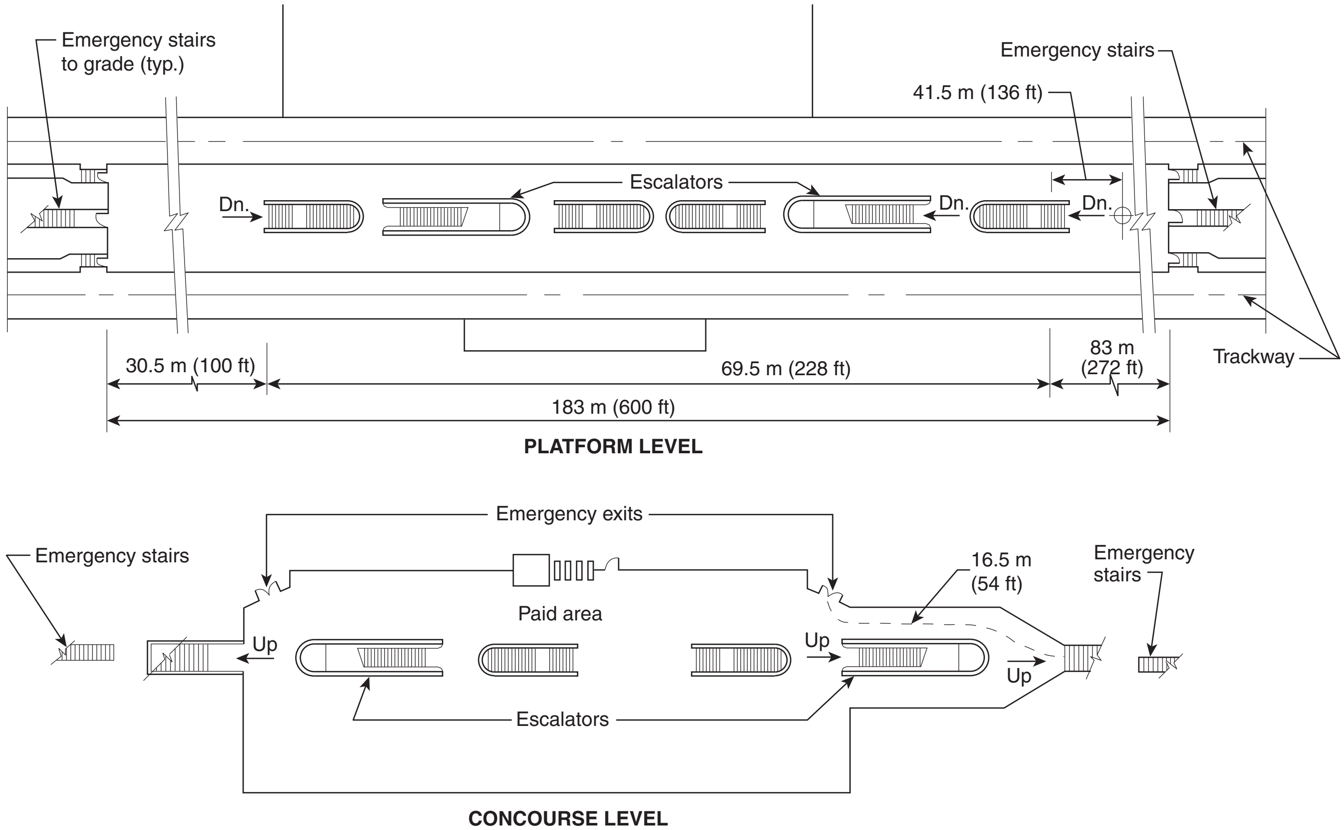

FIGURE C.1.3 Center-Platform Station.

Concourse occupant load = Platform occupant load – (F_p × emergency stair capacity)

Concourse occupant load = 2314 – 513 = 1801 persons

W_{fb} (waiting time at fare barriers) = $F_f - F_p$

$$F_{fb}\left(\text{fare barrier flow time}\right) = \frac{\text{Concourse occupant load}}{\text{Fare barrier exit capacity}}$$

$$F_{fb} = \frac{1801}{560} = 3.22 \text{ minutes}$$

$W_c = F_{fb} - F_p$

$W_{fb} = 3.22 - 3.80 = 0.000$ minutes

W_c (waiting time at concourse exits) = $[F_c - \max\,(F_{fb} \text{ or } F_p)]$

$$F_c\left(\text{concourse exit flow time}\right) = \frac{\text{Concourse occupant load}}{\text{Concourse exit capacity}}$$

$$F_c = \frac{1801}{0} = 0.000 \text{ minutes}$$

$W_c = F_c - \max(F_{fb} \text{ or } F_p)$

$W_c = 0.000 - 3.80 = 0.000$ minutes

Total exit time = $T + W_p + W_{fb} + W_c$

Total exit time = 2.23 + 2.71 + 0.000 + 0.000

Total exit time = 4.94 minutes

In Test No. 2, the time to reach a point outside any enclosing structure is found to be 4.94 minutes. This meets the requirement of 5.3.3.2.

If the concourse of this station is considered to meet the point of safety definition by the authority having jurisdiction, the calculation for Test No. 2 would be modified. The time to reach a point of safety would include the walking travel time from the remote point on the platform to the concourse only, plus the waiting time at the platform exits. The area of the concourse would have to be large enough to accommodate the concourse occupant load calculated in Test No. 2.

C.1.4 Side-Platform Station Sample Calculation. The sample side-platform station is an enclosed station with a concourse above the platform level but below grade. *(See Figure C.1.4.)* The platform is 183 m (600 ft) long to accommodate the train length. The vertical distance from grade to concourse is 8 m (26 ft). The concourse is 5.5 m (18 ft) above the platform.

The sample station has two entrances normally used by patrons, each containing one escalator and one stair. The entrances are covered at grade level to a point 3.05 m (10 ft) beyond the top of the stairs.

The concourse is divided into two free areas and one paid area separated by fare arrays. Each fare array contains 12 fare gates of the turnstile type and one swinging service gate, 1220 mm (48 in.) wide, equipped with panic hardware for use by handicapped persons and service personnel.

Three open wells, containing two stairs and one escalator, communicate between each platform and the concourse.

Elevators are provided from grade level to concourse and from the concourse to each platform for use by handicapped persons and service personnel. Station ancillary spaces are located at concourse level.

Enclosed emergency stairs that discharge directly to grade are provided at both ends of each platform. Escalators are nominal

Table C.1.3 Sample Calculations — Center-Platform Station

Egress Element	mm	in.	p/mm-min	pim	p/min
Platform to concourse (downward)					
Stairs (4)	7320	288	0.0555	1.41	406
Escalators (2*)	1220	48	0.0555	1.41	68
Emergency stairs (2)	2440	96	0.0555	1.41	135
Escalator test: 8.67% (Not > 50%)					609
Through fare barriers					
Fare gates (4) (capacity = 50 per gate)					200
Service gates (1)	1 gate	1 gate	60p/gate/min	60p/gate/min	60
Emergency exit doors (2 x double doors)	3660	144	0.0819	2.08	300
					560
Fare barriers to safe area (fare barriers discharge to outside)					
Stairs	0	0	0.0555	1.41	0
Escalators	0	0	0.0555	1.41	0
Emergency stairs	0	0	0.0555	1.41	0
Escalator test: 0.00% (Not > 50%)					0
Walking Time for Longest Exit Route	**m**	**ft**	**m/min**	**fpm**	**min**
Platform to safe area					
On platform, T_1	41.5	136	37.7	124	1.09
Platform to concourse, T_2	9.1	30	14.6	48	0.62
On concourse, T_3	16.5	54	37.7	124	0.44
Concourse to grade, T_4	0	0	14.6	48	0
On grade to safe area, T_5	3.05	10	37.7	124	0.08
Total walking time, $T = T_1 + T_2 + T_3 + T_4 + T_5$					2.23

*One escalator discounted.

1220 mm (48 in.) wide. Stairs regularly used by patrons are 1830 mm (72 in.) wide. Emergency stairs are 1220 mm (48 in.) wide. Doors to emergency stairs are 1220 mm (48 in.) wide.

The station occupant load is 1600 persons, 228 on the outbound platform and 1372 on the inbound platform.

Table C.1.4 lists the data for the exiting analysis of the sample side-platform station.

The egress capacity from platform to concourse meets the criteria of 5.3.3.1 in Test No. 1, where the time to clear the platform is found to be 3.38 minutes for the inbound platform and 0.56 minute for the outbound platform.

In Test No. 2, the total exit time (i.e., the maximum exit time for the two paths examined) is found to be 5.85 minutes. This meets the criteria of 5.3.3.2.

Evacuate platform occupant load(s) from platform(s) in 4 minutes or less.

Inbound platform:

$$F_{p-i}\left(\text{time to clear platform}\right) = \frac{\text{Platform occupant load}}{\text{Platform egress capacity}}$$

$$F_{p-i} = \frac{1372}{406}$$

$$F_{p-i} = 3.38 \text{ minutes}$$

Outbound platform:

$$F_{p-o}\left(\text{time to clear platform}\right) = \frac{\text{Platform occupant load}}{\text{Platform egress capacity}}$$

$$F_{p-o} = \frac{228}{406}$$

$$F_{p-o} = 0.56 \text{ minutes}$$

F_p for inbound and outbound occupant loads satisfies the criterion of 4 minutes.

Test No. 2. Evacuate platform occupant load from most remote point on platform to a point of safety in 6 minutes or less.

Inbound platform:

W_{p-i} (waiting time at platform egress elements) = $F_{p-i} - T_{1_{p-i}}$

$W_{p-i} = 3.38 - 1.33 = 2.05$ minutes

Concourse occupant load = Platform occupant load – (F_{p-i} × emergency stair capacity)

Concourse occupant load = 1372 – 456 = 916 persons

Outbound platform:

W_{p-o} (waiting time at platform egress elements) = $F_{p-o} - T_{1_{p-o}}$

$W_{p-o} = 0.56 - 0.49 = 0.07$ minute

Concourse occupant load = Platform occupant load – (F_{p-o} × emergency stair capacity)

Concourse occupant load = 228 – 76 = 152 persons

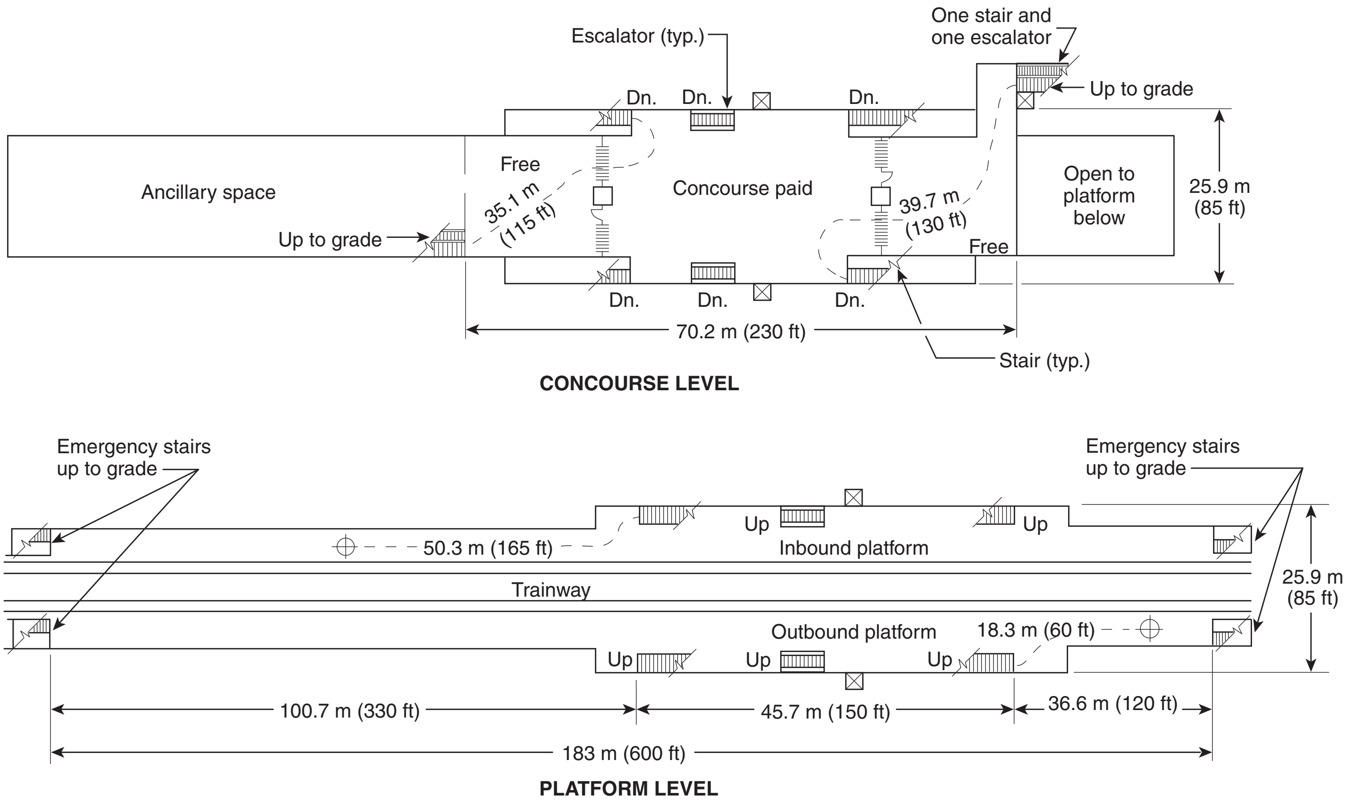

FIGURE C.1.4 Side-Platform Station.

Total concourse occupant load = Concourse load (inbound) + Concourse load (outbound)

Total concourse occupant load = 916 – 152 = 1068 persons

Inbound platform:

W_{fb} (waiting time at fare barriers) = $F_{fb} - F_{p-i}$

$$F_{fb} = \frac{\text{Concourse occupant load}}{\text{Fare barrier egress capacity}}$$

$$F_{fb} = \frac{533}{399}$$

F_{fb} = 1.34 minutes

$W_{fb} = F_{fb} - F_{p-i}$

W_{fb} = 1.34 – 3.66 = 0.00 minutes

W_c (waiting time at concourse egress elements) = $F_c - \max(F_{fb} \text{ or } F_{p-i})$

$$F_c\left(\text{concourse flow time}\right) = \frac{\text{Concourse occupant load}}{\text{Concourse egress capacity}}$$

$$F_c = \frac{533}{94}$$

F_c = 5.68 minutes

$W_c = F_c - \max(F_{fb} \text{ or } F_{p-i})$

W_c = 5.68 – 3.66 = 2.02 minutes

Outbound platform:

W_{fb} (waiting time at fare barriers) = $F_{fb} - F_{p-o}$

$$F_{fb} = \frac{\text{Concourse occupant load}}{\text{Fare barrier egress capacity}}$$

$$F_{fb} = \frac{533}{399}$$

F_{fb} = 1.34 minutes

$W_{fb} = F_{fb} - F_{p-o}$

W_{fb} = 1.34 – 0.61 = 0.73

W_c (waiting time at concourse egress elements) = $F_c - \max(F_{fb} \text{ or } F_{p-o})$

$$F_c = \text{(concourse flow time)} = \frac{\text{Concourse occupant load}}{\text{Concourse egress capacity}}$$

$$F_c = \frac{533}{156}$$

F_c = 3.42 minutes

$W_c = F_c - \max(F_{fb} \text{ or } F_{p-o})$

W_c = 3.42 – 1.34 = 2.08 minutes

Total egress time = $T + W_p + W_{fg} + W_c$

Inbound platform:

Total = 3.49 + 2.32 + 0.00 + 2.02

Total = 7.83 minutes

Outbound platform:

Total = 2.76 + 0.12 + 0.73 + 2.08

Total = 5.69 minutes

Table C.1.4 Sample Calculations — Side-Platform Station

C.1.5 Multilevel-Platform Stations. The procedures for calculating exiting times for multilevel platform stations are similar to the sample calculations in C.1.3 and C.1.4. The changes in the exiting calculations are for multilevel-platform stations primarily a function of the concurrent occupant load determinations for the two platform levels.

The step-by-step procedure relating to the occupant load calculations generally is recommended as follows:

(1) Calculate the occupant load for each platform level as in the appropriate examples in C.1.3 and C.1.4 for the same assumed time(s) of day. Refer also to 5.3.2.3(2) and A.5.3.2.3(2).

(2) If the fire is on the upper-level platform (for an underground station), an assumption can be made as to the percentage of occupants who might be expected to evacuate the lower level through the normal egress routes versus the percentage who might be expected to exit via emergency stairs. These assumptions will be unique for each system as a function of various parameters, including physical configuration of stations, means of egress, and location of emergency exits; communications facilities to advise passengers, both verbal and signing; level of transit personnel working in stations; and transit personnel emergency procedure responsibilities established for the transit operating authority.
(3) The upper-level occupant load is increased by the people evacuating from the lower level through the normal egress routes in accordance with C.1.5(2).
(4) For a fire on the lower level, appropriate assumptions relative to the distribution of the occupant loads to the available means of egress are calculated in a fashion similar to the procedures described above.

The remainder of the exiting calculations essentially are unchanged from the other sample calculations in C.1.3 and C.1.4.

C.2 Escalators. ANSI/ASME A17.1/CSA B44 is generally recognized as the standard governing the installation and maintenance of escalators.

However, considering the critical operational nature of the escalators in stations, specially designed units with additional safety features should be provided.

The number of flat steps at the upper landings should be increased in proportion to the vertical rise of the escalator. For a rise up to 6.1 m (20 ft), there should be two flat steps, the ANSI/ASME A17.1/CSA B44 minimum number of flat steps; from 6.1 m (20 ft) to 18.3 m (60 ft) rise, three flat steps; and over 18.3 m (60 ft) rise, four flat steps.

A remote monitoring panel should be provided in the station that displays the following for each escalator:

(1) Direction of travel
(2) Operating speed (if more than one)
(3) Out-of-service status
(4) Flashing light that indicates the escalator is stopped because of activation of a safety device

Annex D Rail Vehicle Fires

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

D.1 Introduction. This annex provides additional information on the hazards associated with burning vehicles and the impact of a burning vehicle on the evacuation of passengers and crew to a point of safety. Emergency evacuation from a vehicle containing a fire could include exiting a vehicle containing the fire to an adjacent vehicle, exiting the train into the operating environment (station, tunnel, etc.) where the train is located, and moving through the operating environment to the point of safety. Chapter 8 contains minimum prescriptive requirements that are intended to provide sufficient time for passengers and crew to safely evacuate from a train containing a fire. This annex provides guidance for designing and evaluating train fire performance. A fire involving a train will have an impact on the conditions in the operating environment, and this type of fire is often used to design emergency systems in operating environments. Chapters 5 through 7 provide requirements on design of the operating environment to ensure that passengers can safely egress to a point of safety.

D.2 Initial Fire Development Inside Vehicles. The development of a fire inside a vehicle is dependent on the fire performance of interior finish materials, the size and location of the initiating fire, the size of the enclosure where the fire is located, and the ventilation into the enclosure.

D.2.1 Material fire performance is most often considered in the evaluation of fire performance of the vehicle. Material fire performance is measured in terms of ignitibility, heat release rate, and smoke and toxic gas production. Flame spread and fire development are dependent on the material's ignitibility and heat release rate as well as the severity of the initiating fire and surrounding environment.

D.2.1.1 The ignitibility, heat release rate, and smoke and toxic gas production can be measured in the ASTM E 1354 cone calorimeter. It is recommended that all combustible materials on a train be tested in the cone calorimeter. At a minimum, tests should be conducted at a heat flux of 50 kW/m^2 in duplicate. For a more detailed evaluation of the material performance, cone calorimeter tests should be performed at three different heat fluxes where the material ignites (e.g., 25, 50, and 75 kW/m^2). The cone calorimeter can also be used to measure the critical heat flux of the material, which is the lowest heat flux at which the material will ignite. The critical heat flux can be used to determine the ignition temperature of the material. Analysis to predict flame spread along materials will require the more detailed set of cone calorimeter data along with the critical heat flux of the material.

D.2.1.2 In Chapter 8, the minimum fire performance of many interior finish materials is required to be measured using the ASTM E 162 flame spread test. Though this downward flame spread test will screen out many poorly performing materials, the test does not provide a measure of wind-aided flame spread (i.e., upward flame spread or flame spread along a ceiling). Wind-aided flame spread is the fastest type of flame spread and is the type of flame spread that will cause the maximum surface area of material to become involved in the fire. The amount of upward flame spread is affected by the size of the initiating fire and the material fire performance. Some materials might not exhibit any flame spread when exposed to a small fire (e.g., a newspaper fire), but when exposed to something slightly larger (e.g., burning bag of trash with paper and plastic) will readily spread flame.

D.2.1.3 Smoke and toxic gas production can have an impact on the operating environment through which passengers will need to evacuate. Some materials naturally produce more smoke and toxic gases. Some fire-retardant additives can cause more smoke and toxic gases to be produced compared to untreated materials. The amount of smoke and toxic gas produced will be a function of the amount of material burning. Therefore, limiting fire propagation on materials will also help limit the amount of smoke and toxic gas production.

D.2.2 The size and location of the initiating fire will have a significant impact on whether materials become ignited and spread flame. Materials exposed to higher levels of heat (heat fluxes) will ignite more readily, release more heat, and usually will result in more flame spread. Research has shown that increasing the physical size and the heat release rate of the fire will increase the heat flux produced by the initiating fires. Increasing the heat release rate of the fire will also increase the flame height, which will expose larger areas of material to the high heat fluxes in the flaming region. The location of the initiating fire will also affect the heat fluxes produced by the fire. For the same size fire, higher heat fluxes are produced when the fire is located in a corner instead of against a flat wall.

D.2.3 The gas temperature inside of the enclosure containing a fire can have a significant impact on the growth rate of the fire. Elevated gas temperatures will pre-heat unignited material and will potentially accelerate flame spread across the material. Gas temperatures in an enclosure can be affected by the size of the enclosure, the ventilation into the enclosure, and the heat release rate of the fire. The gas temperature will increase when the enclosure size is decreased and the heat release rate is increased.

D.3 Fire Development Outside Vehicles. Outside a vehicle, flames can spread along continuous pieces of combustible materials or ignite adjacent materials if exposed to sufficient heat. Underneath vehicles, combustible items that are adequately spaced will prevent the spread of fire. If the car is moving, flames can be longer, making safe separation distances longer. It might also be possible for flames from fires underneath vehicles to extend out to the sides and ends of the vehicle. These undercar fires can ignite and initiate flame spread along combustible materials on the sides and ends of the vehicle. Combustible materials on the sides and ends of the vehicle might also be vulnerable to other types of fires that could occur on the exterior of the vehicle.

D.3.1 An increasing amount of the exterior vehicle body is being manufactured of fiber-reinforced resin composite materials. End caps have been made of composite materials for years, and other vehicle body components are being constructed of composite materials to make vehicles lighter in weight. Even if these materials meet the ASTM E 162 requirement in Chapter 8, they can ignite and flames can spread up the height of the vehicle exterior.

D.3.2 Initiating fires on the exterior of the vehicle could range from a small trash fire to a vehicle fire. Although the trash fire might be small, it could be possible for it to ignite combustible components on the exterior and for flames to spread up the vehicle. Some trains are operated in close proximity to automobiles. Automobile fires can become quite large (~5 MW) and can include fuel spills. If such a fire occurred close to a train, the fire could ignite nearby combustible exterior components on the vehicle.

D.3.3 Connections between vehicles can be particularly vulnerable to exterior fires. Some vehicles are connected by articulating bellows, which are constructed of relatively thin, flexible, combustible materials. The materials used for these components should be carefully screened to ensure that exterior fires do not extend into the vehicle before passengers have been safely evacuated.

D.3.4 Spread of fire from one vehicle to an adjacent vehicle can cause the total heat release rate of the train fire to significantly increase. This could occur if the fire on the outside of one vehicle radiates enough heat to ignite the combustible components of the adjacent vehicle. Vehicle-to-vehicle spread could also occur if a fire inside a vehicle has reached flashover and flames extending outside of the vehicle through windows or doors are able to ignite the nearby vehicle.

D.4 Vehicle Fire Heat Release Rate History. The heat release rate history of a vehicle fire should include the heat release rate during all stages of the fire. Fires inside of vehicles that are allowed to grow sufficiently large can reach flashover, where all of the items inside of the vehicle ignite. The largest heat release rates are expected after flashover occurs (i.e., postflashover). The heat release rate during postflashover is particularly important since many tunnel and station smoke control system designs are based on the maximum expected heat release rate. The heat release rate of the vehicle fire will also affect the heat that passengers could be exposed to during evacuation. The magnitude of the heat release rate during postflashover will be a function of the amount of air drawn into the vehicle, the material fire properties, and the potential heat release rate of the burning fuels inside of the vehicle.

D.4.1 The fire properties of a material will determine the impact of the material on the postflashover fire conditions. The postflashover fire is a balance of heat gains and heat losses. As a result, the ratio between the material heat of combustion and heat of gasification is particularly important. The heat of combustion is the amount of energy produced per gram of material burned (heat gain), while the heat of gasification is the energy required to convert solid material into gas (heat loss). If this ratio is high (heat of combustion several times greater than the heat of gasification), then the material will contribute more heat to the fire compared with the amount it takes to produce the gas. This scenario will result in a more intense fire. As the ratio becomes closer to 1, the fire will burn with less intensity. Depending on the conditions, materials with a ratio close to 1 might not be able to self-support a postflashover fire environment.

D.4.2 The amount of air drawn into a postflashover fire will be a function of the number of ventilation openings. Initially, this could be doors or windows where passengers have evacuated from the train. Many vehicles will contain mostly polycarbonate windows. As the fire continues to burn, polycarbonate windows will thin and begin to develop holes (Strege et al.). Glass windows will crack, shatter, and fall out. Eventually, these areas will be completely open to allow air in and smoke to exhaust from the vehicle fire.

D.4.2.1 The impact of additional ventilation openings is dependent on the heat losses and gains to the vehicle fire. Additional openings will allow more energy to be lost from the vehicle fire through radiation and convection. However, the additional air into the vehicle fire allows more heat to be released inside the vehicle. If the fuels inside the vehicle can produce a heat release rate, then the fire will burn at that higher heat release rate. It is also possible that when the windows fail, the energy losses might outweigh the heat that can be produced by the materials, and the fire will begin to diminish in size. This also happens when the fire begins to go into the decay stage: the fire inside of the vehicle can no longer produce sufficient heat to outweigh the heat losses.

D.4.3 The heat release rate of the train fire will also affect the amount of heat the passengers are exposed to during the evacuation. Larger heat release rate fires will produce longer flames that could extend out of the vehicle openings. If the vehicle is inside a tunnel, these flames could impinge on the ceiling and extend down away from the burning vehicle. Radiation from these flames to nearby evacuating passengers could be significant.

D.5 Volume of Smoke Produced by Burning Vehicles.

D.5.1 The volume of smoke produced by a fire is dependent on the entrainment into the smoke plume. The entrainment into the smoke plume varies depending on the geometry. For example, a free-burning circular pool fire will produce a different volume of smoke compared with the same heat release rate fire burning in a line. Natural or ventilation-induced air currents can have an impact on entrainment.

D.5.2 Volume of smoke from fires inside of vehicles will be exhausted out of the vehicle through open doors or window openings. As a result, the volume of smoke produced by a vehicle fire will be the smoke volume produced by a series of window plumes. The volume of smoke produced will be dependent on how high the gases are allowed to rise before they impinge on the ceiling or reach the upper smoke layer interface.

D.5.3 Volume of smoke from undercar fires or fires involving the outside of the vehicle can be modeled by assuming that the fire is a line fire. The volume of smoke produced will be dependent on how high the gases are allowed to rise before they impinge on the ceiling or reach the upper smoke layer interface.

Annex E Fire Hazard Analysis Process

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

E.1 Introduction. This annex was prepared to provide expanded understanding of the process required to conduct a fire hazard analysis for fixed guideway and passenger rail vehicles. NFPA *101* [1] and other cited references provide more complete information.

E.2 Fire Hazard Analysis. The prescriptive-based vehicle fire performance requirements in Chapter 8 of this standard are based on individual material tests. With the use of the fire hazard analysis process, it should be possible to ascertain the fire performance of vehicle materials and assemblies in the context of actual use. The result of such a fire hazard analysis should be a clear understanding of the role of materials, geometry, and other factors in the development of fire in the specific vehicles studied. By identifying when or if specific conditions are reached such that materials begin to contribute to the fire hazard, fixed guideway transit and passenger rail systems vehicle designers and authorities having jurisdiction will have a better foundation on which to base appropriate vehicle and system design and the evaluation of the fire performance of such vehicle designs. By showing the relative contribution of a particular design feature or material, it is possible to make a more realistic assessment of the necessity for specific vehicle design requirements to meet fire/life safety objectives and criteria.

The *SFPE Engineering Guide to Performance-Based Fire Protection Analysis and Design of Buildings* [2] provides a framework for these assessments. Other useful references include ASTM E 2061 [3] and APTA RP PS-005-01a [4]. On May 12, 1999, the Federal Railroad Administration (FRA) issued a rule containing passenger rail equipment fire safety regulations [5]. The FRA issued a clarification/revision of the fire safety regulations on June 25, 2002 [6]. 49 CFR 238.103 requires that materials used for passenger rail cars and locomotive cabs meet certain fire safety performance criteria and that fire safety (e.g., hazard) analysis be conducted for all new and existing rail passenger equipment.

In addition, scenarios are used to assess the adequacy of vehicle designs considered and ultimately selected. Accordingly, initiating events as referenced from the ASTM rail fire assessment guide [3] are specified for analysis. Although developed for the analysis of existing equipment, the APTA-recommended fire safety practice provides a framework and resources for the application of fire hazard analysis in vehicles that might be applicable to new or retrofitted equipment.

Finally, it is important to note that the fire hazards relating to the vehicle-operating environment must be considered.

If the outcome predicted by assessment of the scenarios evaluated is bound by the performance criteria stated, then the objectives will have been met, and the life safety characteristics of a proposed vehicle design can be considered to be consistent with the goals of this standard. It must be assumed that if a design fails to comply with the life safety goals and objectives and associated performance criteria, the design must be changed and reassessed iteratively until satisfactory performance levels are attained.

On June 25, 2002, the FRA published a Federal Register Notice that clarified several items relating to the fire tests and performance criteria, and revised certain parts of the fire safety analysis requirements [6].

Documentation of assessment parameters, such as those used with scenarios, is critical. The approval and acceptance of a fire/life safety design is dependent on the quality of the documentation used in this process.

E.3 Overview of Fire Hazard Analysis Process for Vehicles. The information in this section is based on a research study sponsored by the FRA. Additional details of the research program are available [7].

ASTM E 2061 [3] provides resources and references for the application of fire hazard analysis techniques to rail vehicles but is not intended to provide a specific prescriptive standard or method. Part of the purpose of NFPA 130 is to provide such a specific method for the application of fire hazard analysis tools and the ASTM guide when applied to specific vehicle designs.

Traditionally, fire hazard analysis techniques involve a four-step process for the evaluation of a product or products in a specific scenario. The four steps are as follows:

(1) Define the context.
(2) Define the scenario.
(3) Calculate the hazard.
(4) Evaluate the consequences. [8]

For the analysis of vehicles, this process limits the evaluation to the contribution of specific materials and products without providing an overall assessment of the fire performance of the entire system.

The traditional four-step evaluation process can be extended to better reflect the minimum appropriate performance of the overall vehicle system while maintaining the evaluation of a specific design compared against the required baseline. For this systems-based analysis, the process is also conducted in four steps, as follows:

(1) Define vehicle performance objectives and design.
(2) Calculate vehicle fire performance.
(3) Evaluate specific vehicle fire scenarios.
(4) Evaluate vehicle car design suitability.

Steps 1 and 4 are largely subjective and depend on the expertise of the user. Step 2 can involve hand calculations or some use of computer modeling software. The heart of Step 2 is a sequence of procedures to calculate the development of hazardous conditions over time, to calculate the time needed by occupants to escape under those conditions, and to estimate the resulting effects on the vehicle occupants, based on tenability criteria. In addition to evaluating the hazard resulting from specific materials and components used in the vehicle design, Step 2 determines the worst-case fire that allows the overall vehicle system to meet chosen design criteria. Step 3 evaluates the specific fires that are likely to occur. Step 4 compares the results of Steps 2 and 3 and evaluates the appropriateness of the calculations performed, as well as determines whether the proposed design meets the performance objectives and design established in Step 1. The procedure in Table E.3 shows each step in the process tailored for rail vehicle design.

E.3.1 Step 1: Define Vehicle Performance Objectives and Design. Both the proposed performance objectives and the vehicle design must be defined. Clear goals and objectives with well-defined acceptance criteria quantify the minimum acceptable performance that must be met in the final vehicle design. These will all be provided by the responsible fixed guideway transit or passenger railroad system, by the authorities having jurisdiction, and by expert engineering judgment based on the performance of the existing acceptable vehicle designs and the operating environment. For example, an objective might be to provide life safety for passengers in the event of a fire or to minimize damage to property. Performance criteria are more specific and might include limits on temperature of materials, gas temperatures, smoke concentration or obscuration levels, concentration of toxic gases, or radiant heat flux levels, to allow for sufficient time to evacuate occupants to a point of safety.

The analysis requires a detailed understanding of the geometry (e.g., configuration) of the system being considered, including construction materials, sizes, and connections for all compartments, typical furnishings, and other design parameters that might affect the fire. Such parameters might include fire detection or suppression systems, ventilation systems, and emergency exits and procedures.

E.3.2 Step 2: Calculate Vehicle Fire Performance. The second step determines the response of the vehicle system to a range of chosen design fires. This response can be expressed in the form of one or more fire performance graph(s), which present the calculated design criterion as a function of the size of the fire. In addition, the minimum acceptable performance criteria are determined by calculation or specification. For example, a fire performance graph might show the available egress time as a function of the fire size in a vehicle, and the minimum acceptable performance criterion might be the time necessary for passengers to safely evacuate the vehicle. These criteria can be specified by the fixed guideway transit or passenger railroad system, by authorities having jurisdiction, or by expert engineering judgment based on the performance of the existing acceptable designs.

Table E.3 System of Vehicle Fire Hazard Analysis Steps

Step 1: Define vehicle performance objectives and design.	(a) Clearly define fire performance objectives. (b) Determine the geometry of the vehicle. (c) Include other design parameters that might have an impact on a possible fire, such as a tunnel operating environment, material controls, fire detection and suppression, or other system procedures.
Step 2: Calculate vehicle fire performance.	(a) Determine minimum acceptable performance criteria based on the vehicle design. (b) Establish standard design fires. (c) Use predictive calculation and/or model calculations, to determine the fire performance of the proposed design for a range of design fires. (d) Create a fire performance graph.
Step 3: Evaluate specific vehicle fire scenarios.	(a) Examine relevant fire incident experience with same/similar applications. (b) Identify the likely role/involvement of application contents in fire. (c) Ask which fires are most common/likely? Most challenging? (d) Quantify the burning behavior for chosen scenarios from available fire test data or appropriate small- and large-scale tests.
Step 4: Evaluate suitability of vehicle design.	(a) Estimate through expert judgment, regulatory guidance, and, when needed, complementary small- and large-scale tests the effects of unknowns not accounted for in the fire performance graphs. (b) Establish the sensitivity of the fire performance graph to known inputs. (c) Set appropriate design margins. (d) Determine the acceptability of the design.

Once the detailed problem has been defined, this information can be used as input to a hand calculation or computer fire model to predict conditions within each compartment of the vehicle as a function of time. For this analysis, these conditions include temperature, hot gas layer position (typically termed *interface height*), visibility, and toxic gas concentrations throughout the car. These conditions are used to calculate tenability within the car. Conditions are considered untenable when there is a threat to passenger life safety, evaluated as an elevated temperature, products of combustion exposure, or a combination of the two. The time at which conditions within the vehicle become untenable for each design fire are plotted as a function of the size of the design fire to produce a fire performance graph for each application.

The calculation of minimum necessary egress time, whether from a building or a vehicle, involves many assumptions. Several models can be used to increase the confidence in the egress time calculation. It is important to remember that the minimum necessary egress time does not include panic, scattered luggage in a postcrash vehicle, or bodily injury to occupants prior to evacuation commencement. An appropriate design margin applied to the model time should account for such limitations. Typically, a factor of 2 is used as a design margin [9].

E.3.3 Step 3: Evaluate Specific Vehicle Fire Scenarios. Step 3 evaluates possible vehicle fire scenarios in order to place the fire performance curves in context and to allow the designer to adopt reasonable design margins in the final vehicle design evaluation in Step 4. A significant amount of information relevant to scenario definition can be obtained from historical fire incident experience [10, 11]. Databases such as the National Fire Incident Reporting System (NFIRS) contain relevant vehicle data, normally segregated into specific categories [12].

Representative fire scenarios include the following:

(1) Ignition under a seat by a small source (e.g., crumpled newspaper)
(2) Ignition source on top of a vandalized seat (e.g., crumpled newspaper)
(3) Overheated equipment (e.g., electrical, HVAC)

The location of the train must be also considered in the analysis. For example, the fire risk to occupants is greater if the train is located between stations or within a tunnel.

More detailed information describing passenger-carrying vehicle fire scenarios is contained in the ASTM guide and the APTA recommended practice cited earlier in Section E.2. Relevant data describing specific fires appropriate for the vehicle application are defined and used as input to the same fire model used in Step 2. The results of these model calculations can be compared to the design fires used in Step 2 to define appropriate design margins for analysis.

E.3.4 Evaluate Suitability of Vehicle Design. Taking into account the results of the calculations and using engineering judgment, experience, and the requirements of the authorities having jurisdiction, an appropriate design margin is decided upon and applied to the minimum acceptable criteria. If the worst-case vehicle fire scenarios are all less hazardous than the minimum criteria multiplied by the design margin, then the vehicle design is said to be acceptable.

Finally, the results of any analysis should be challenged by the user's common sense and experience. Results that violate these should be questioned and resolved. Comparisons should be made to data from similar experiments or actual passenger train fires wherever possible. If such data are not available, it might be advisable to conduct verifying tests in situations where public safety is at risk.

The outcome of the fire hazard analysis will be a statement of whether the vehicle design under consideration constitutes a threat above acceptable limits. Further analysis can ascertain whether compartmentation, detection and suppression systems, and other intervention strategies can further minimize the fire hazard.

Annex F Creepage Distance

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

F.1 Table F.1 lists the minimum creepage distance for transit vehicles.

Table F.1 Minimum Creepage Distance for Transit Vehicles

Class		Low Energy		Ordinary (Enclosed Environment with Breathing)		Underfloor Exposed Environment		Highly Exposed (No External Protection)	
Application		Electronic and Protected Electronic Devices (½ Amp Where Max.)		Control and Power Devices Mounted in Control Group Enclosures (Short Circuit Limits)		Power Resistors Open Disconnect Devices Mounted Outside Protective Enclosures		Third Rail Shoe Beams and Current Collection Devices (Short Circuit Unlimited by Onboard Devices)	
Nominal Voltage	Surface	mm	in.	mm	in.	mm	in.	mm	in.
37.5	Horizontal	1.6	1⁄16	3.2	⅛	19.1	¾	N/A	N/A
	Vertical	1.6	1⁄16	3.2	⅛	12.7	½	N/A	N/A
74	Horizontal	3.2	⅛	6.5	¼	40	1 9⁄16	N/A	N/A
	Vertical	3.2	⅛	6.5	¼	25	1	N/A	N/A
230	Horizontal	8.3	⅜	15.9	⅝	76.2	3	101.6	4
	Vertical	8.3	⅜	15.9	⅝	50.8	2	57.2	2¼
600	Horizontal	19.1	¼	31.8	1¼	177.8	7	254	10
	Vertical	19.1	¼	31.8	1¼	127	5	152.4	6
750	Horizontal	*	*	40	1 9⁄16	*	*	*	*

* Where no value is given or for nonstandard values, the creepage distance should be agreed upon between the supplier and the AHJ. EN 50124-1, while not as conservative as the requirements of this standard, provides a basis for discussion of alternative requirements.

Annex G On-board Fire Suppression System

G.1 On-board fire suppression systems (e.g., mist systems), while relatively new in the passenger rail and fixed guideway industry have been successfully used on a number of passenger rail and diesel powered light rail systems outside of the United States. The applications for this type of system can range from protection of diesel engine compartments to the interior of passenger rail vehicles. The use of a fire suppression system may save lives in the incident vehicle during a fire condition; minimize damage to the train, tunnel and the station which it has entered; reduce or eliminate potential use of station sprinklers; reduce or eliminate the need for downstands; significantly reduce the impact of designing for fire emergencies on station architecture; reduce tunnel ventilation capacities by approximately 40 percent; reduce the number and/or diameter of emergency ventilation fans at each end of each station and within the tunnels, thus reducing structure sizes; decrease shaft airflow cross section areas by approximately 40 percent; and decrease tunnel ventilation shaft portal areas that correspond to the required fans sizes/velocities. When considering the addition of a fire suppression system, several design challenges should be met by the rail vehicle manufacturer. These challenges include the type of extinguishing medium used, which all must be approved by the AHJ the size and number of medium canisters and where on the vehicle to place them for easy access for maintenance; the resultant increased energy consumption caused by the increase in weight of the suppression system; the maintenance intervals; the cost of the system; the testing and commissioning of the system; and the cost and difficulties associated with retrofitting vehicles.

NFPA® 140

Standard on

Motion Picture and Television Production Studio Soundstages, Approved Production Facilities, and Production Locations

2013 Edition

This edition of NFPA 140, *Standard on Motion Picture and Television Production Studio Soundstages, Approved Production Facilities, and Production Locations*, was prepared by the Technical Committee on Motion Picture and Television Industry. It was issued by the Standards Council on November 27, 2012, with an effective date of December 17, 2012, and supersedes all previous editions.

This edition of NFPA 140 was approved as an American National Standard on December 17, 2012.

Origin and Development of NFPA 140

The 1999 edition of NFPA 140, *Standard on Motion Picture and Television Production Studio Soundstages and Approved Production Facilities*, was the first standard developed by the Technical Committee on Motion Picture and Television Industry. It closely paralleled a standard in effect in the state of California.

The 2004 edition incorporated minor reformatting mandated by the *Manual of Style for NFPA Technical Committee Documents*.

The 2008 edition was expanded to include requirements for production locations (i.e., “shooting on location”), and the title was changed to reflect that inclusion.

Revisions to the 2013 edition include new requirements that soundstage audiences be provided with instructions relative to location of exits and means that will be used to notify them in the event of fire or other emergency; use, mixing, dispensing, or storage of flammable and combustible liquids must be per fire code; hydrants, standpipes, and fire department connections must not be blocked, obstructed, or rendered inoperative; and grounding must by bonded per *NFPA 70®*, *National Electrical Code®*, where power from both mobile generators and site electrical services are used to energize equipment.

This list represents the membership at the time the Committee was balloted on the final text of this edition. Since that time, changes in the membership may have occurred. A key to classifications is found at the back of the document.

NOTE: Membership on a committee shall not in and of itself constitute an endorsement of the Association or any document developed by the committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on the hazards associated with practices, processes, materials, and facilities associated with motion picture and television production.

NFPA 140

Standard on

Motion Picture and Television Production Studio Soundstages, Approved Production Facilities, and Production Locations

2013 Edition

IMPORTANT NOTE: This NFPA document is made available for use subject to important notices and legal disclaimers. These notices and disclaimers appear in all publications containing this document and may be found under the heading "Important Notices and Disclaimers Concerning NFPA Documents." They can also be obtained on request from NFPA or viewed at www.nfpa.org/disclaimers.

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates that explanatory material on the paragraph can be found in Annex A.

Changes other than editorial are indicated by a vertical rule beside the paragraph, table, or figure in which the change occurred. These rules are included as an aid to the user in identifying changes from the previous edition. Where one or more complete paragraphs have been deleted, the deletion is indicated by a bullet (•) between the paragraphs that remain.

A reference in brackets [ ] following a section or paragraph indicates material that has been extracted from another NFPA document. As an aid to the user, the complete title and edition of the source documents for extracts in mandatory sections of the document are given in Chapter 2 and those for extracts in informational sections are given in Annex B. Extracted text may be edited for consistency and style and may include the revision of internal paragraph references and other references as appropriate. Requests for interpretations or revisions of extracted text shall be sent to the technical committee responsible for the source document.

Information on referenced publications can be found in Chapter 2 and Annex B.

Chapter 1 Administration

1.1 Scope.

1.1.1* This standard shall address fire protection, property protection, and life safety in motion picture and television industry soundstages, approved production facilities, and production locations.

1.1.2 Practices, processes, materials, and facilities that are addressed by other NFPA standards shall be governed by those standards unless modified herein.

1.2 Purpose. The purpose of this standard shall be to provide minimum requirements for the design, construction, operation, and maintenance of soundstages and approved production facilities, as well as the use of production locations, for motion picture and television industry productions.

1.3 Application.

1.3.1 This standard shall apply to the following:

(1) New buildings, or portions thereof, used as soundstages or approved production facilities in motion picture and television industry productions
(2) Existing buildings, or portions thereof, used as soundstages or approved production facilities in motion picture and television industry productions to the extent specifically required by other portions of this document
(3) Additions to buildings used as soundstages or approved production facilities in motion picture and television industry productions
(4) Alterations, modernizations, or renovations of existing buildings used as soundstages or approved production facilities in motion picture and television industry productions
(5) Existing buildings, or portions thereof, upon change of occupancy for use as soundstages or approved production facilities in motion picture and television industry productions
(6) Production locations used in motion picture and television industry productions

1.3.2 That portion of the standard dealing with operating features shall apply to new and existing soundstages, approved production facilities, and production locations. *(See Chapter 6.)*

1.3.3 Existing soundstages, approved production facilities, and production locations that are in conformance with requirements of the authority having jurisdiction at the time of the adoption of this standard shall be permitted to remain in use under the following conditions:

(1) The occupancy classification and use remain the same.
(2) No serious hazards to life safety exist that would constitute an imminent threat.

1.3.4 This standard shall not apply to facilities or locations used exclusively for radio broadcasts, theaters and auditoriums, live broadcasts of news or sporting events, and postproduction facilities.

1.4 Equivalency. Nothing in this standard shall be intended to prevent the use of systems, methods, or devices of equivalent or superior quality, strength, fire resistance, effectiveness, durability, and safety as alternatives to those prescribed by this standard, provided that technical documentation is submitted to the authority having jurisdiction to demonstrate equivalency, and the system, method, or device is approved for the intended purpose.

Chapter 2 Referenced Publications

2.1* General. The documents or portions thereof listed in this chapter are referenced within this standard and shall be considered part of the requirements of this document.

2.2 NFPA Publications. National Fire Protection Association, 1 Batterymarch Park, Quincy, MA 02169-7471.

Chapter 3 Definitions

3.1 General. The definitions contained in this chapter shall apply to the terms used in this standard. Where terms are not defined in this chapter or within another chapter, they shall be defined using their ordinarily accepted meanings within the context in which they are used. *Merriam-Webster's Collegiate Dictionary*, 11th edition, shall be the source for the ordinarily accepted meaning.

3.2 NFPA Official Definitions.

3.2.1* Approved. Acceptable to the authority having jurisdiction.

3.2.2* Authority Having Jurisdiction (AHJ). An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

3.2.3 Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

3.2.4* Listed. Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

3.2.5 Shall. Indicates a mandatory requirement.

3.2.6 Should. Indicates a recommendation or that which is advised but not required.

3.2.7 Standard. A document, the main text of which contains only mandatory provisions using the word "shall" to indicate requirements and which is in a form generally suitable for mandatory reference by another standard or code or for adoption into law. Nonmandatory provisions are not to be considered a part of the requirements of a standard and shall be located in an appendix, annex, footnote, informational note, or other means as permitted in the *Manual of Style for NFPA Technical Committee Documents.*

3.3 General Definitions.

3.3.1 Approved Production Facility. An existing building, portion of a building, or group of buildings renovated, modified, or reconstructed for use by the entertainment industry and approved by the authority having jurisdiction for the purposes of motion picture, television, or commercial production.

3.3.2 Motion Picture Production Studio. See 3.3.5, Production Studio.

3.3.3 Platform. The raised area within a building used for the presentation of music, plays, or other entertainment. [***101,*** 2012]

3.3.4 Production Location. Any site other than a soundstage or approved production facility used for the purpose of motion picture, television, or commercial production.

3.3.5 Production Studio. A building, a portion of a building, or a group of buildings designed and constructed for use by the entertainment industry for the purpose of motion picture, television, or commercial productions, or broadcasting television programs utilizing a soundstage.

3.3.6 Set. A structure built or assembled for the purpose of motion picture, television, or commercial productions.

3.3.7 Soundstage. A building or a portion of a building, usually insulated from outside noise and natural light, used by the entertainment industry for the purpose of motion picture, television, or commercial productions.

3.3.8 TV Production Studio. See 3.3.5, Production Studio.

Chapter 4 Soundstages and Approved Production Facilities

4.1 General. This chapter shall apply to new and existing motion picture and television soundstages and approved production facilities.

4.2 Permits. Where required by the AHJ, a permit shall be obtained for any of the activities that follow:

(1) Use of pyrotechnic special effects
(2) Use of open flames
(3) Welding
(4) Use of flammable or combustible liquids or gases

(5) Use of aircraft
(6) Presence of motor vehicles within a building
(7) Productions with live audiences
(8)*Change of use or change of occupancy classification

4.3 Pyrotechnic Special Effects and Open Flames.

4.3.1* The use of pyrotechnic special effects and open flames shall be subject to the approval of the AHJ.

4.3.2 When an audience is present, NFPA 1126, *Standard for the Use of Pyrotechnics Before a Proximate Audience*, shall be used to regulate any pyrotechnic use.

4.3.3 When an audience is present, NFPA 160, *Standard for the Use of Flame Effects Before an Audience*, shall be used to regulate any flame effects use.

4.4 Standby Fire Personnel.

4.4.1 Where required by the AHJ, standby fire personnel shall be provided for soundstages and approved production facilities where pyrotechnic special effects are used.

4.4.2 Other Hazards. Where required by the AHJ, standby fire personnel shall be provided for hazardous operations other than pyrotechnic special effects.

4.5 Decorative Materials.

4.5.1 Foamed plastic materials used for decorative purposes, scenery, sets, or props shall have a heat release rate not exceeding 100 kW where tested in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*, or where tested in accordance with NFPA 289, *Standard Method of Fire Test for Individual Fuel Packages*, using the 20 kW ignition source.

4.5.2 Combustible drapes, drops, and any other similar combustible hangings or vertically placed materials shall comply with one of the following options:

(1) The materials meet the requirements of NFPA 701, *Standard Methods of Fire Tests for Flame Propagation of Textiles and Films.*
(2) The materials exhibit a heat release rate not exceeding 100 kW when tested in accordance with NFPA 289, *Standard Method of Fire Test for Individual Fuel Packages*, using the 20 kW ignition source.
(3) The materials are present in such limited quantity that a hazard of fire development or spread is minimal.
(4)*The materials are considered by the AHJ to exhibit acceptable fire performance.
(5)*Approved interim measures are provided for the period during which the combustible materials are present.

4.5.3 Cut greens shall be treated with an approved or listed fire retardant, and the process shall be repeated as often as necessary to maintain its effectiveness.

4.6 Smoking.

4.6.1 Smoking shall be prohibited on soundstages and in approved production facilities unless otherwise provided in 4.6.2 or 4.6.3.

4.6.2 Smoking shall be permitted when it is a necessary part of a performance, and only when the smoker is a member of the cast.

4.6.3 Except where prohibited by the AHJ, smoking shall be permitted where all of the following conditions are met:

(1) The smoking area is outdoors.
(2) Hazardous materials are not present.
(3) Approved ash trays or receivers are provided.

4.7 Structural Loads.

4.7.1 Approved production facilities and soundstages shall be designed, constructed, or altered to sustain all structural load combinations in accordance with the local building code.

4.7.2 Where the anticipated loads exceed those specified in the local building code for the purpose of suspending sets, ceilings, backings, and other heavy production set pieces, the building shall be designed and constructed for the additional loads.

4.8 Electrical Requirements.

4.8.1 Electrical equipment shall be in accordance with *NFPA 70, National Electrical Code.*

4.8.2* Soundstages and approved production facilities shall be provided with a minimum of 35 W/ft^2 (377 W/m^2) dedicated for production lighting and power.

4.8.3 The electrical distribution equipment used shall comply with UL 1640, *Standard for Portable Power-Distribution Equipment*, and the provisions of Article 530 of *NFPA 70, National Electrical Code.*

4.8.4 The wiring method to electrical distribution equipment shall comply with the provisions of Article 530 of *NFPA 70, National Electrical Code.*

4.8.5 The location of portable, mobile, or stationary power-generating equipment shall be subject to the approval of the AHJ.

4.8.6 Exterior penetrations shall be located near the predesignated location for portable and mobile power-generating equipment.

4.8.7 Auxiliary power cables supplied from mobile generators or adjacent buildings shall not be routed through fire-rated windows and doors.

4.8.8 Portable feeder cables shall be permitted to temporarily penetrate fire-rated walls, floors, or ceilings provided that all of the following apply:

(1) The opening is of noncombustible material.
(2) When in use, the penetration is sealed with a temporary seal of a listed firestop material.
(3) When not in use, the opening shall be capped with a material of equivalent fire rating.

[**70:**530.18(C)]

4.8.9 Where the penetration utilizes a conduit, metal-threaded caps shall be attached to the pipe by means of chain or cable and shall effectively cap the conduit when not in use.

4.8.10 The lighting equipment used shall comply with UL 1573, *Standard for Stage and Studio Luminaires and Connector Strips*, and the provisions of Article 530 of *NFPA 70, National Electrical Code.*

4.9 Fire Department Access. Fire department access shall be maintained as required by the AHJ.

4.10 Means of Egress.

4.10.1 Means of egress shall be in accordance with NFPA *101, Life Safety Code*, unless otherwise modified by 4.10.2 through 4.10.6.

4.10.2 The maximum travel distance to an exit within the soundstage shall be 150 ft (45 m).

4.10.3 Soundstages and approved production facilities shall have an aisle along the perimeter of the soundstage or facility as approved by the AHJ unless otherwise provided in 4.10.3.2.

4.10.3.1 A clear unobstructed aisle height of 7 ft (2.1 m) shall be maintained.

4.10.3.2 A soundstage or approved production facility with a gross area not exceeding 1500 ft^2 (139 m^2) shall be exempt from the perimeter aisle requirement of 4.10.3 provided there is a minimum of two means of egress.

4.10.4 Emergency lighting shall be provided for the means of egress in accordance with NFPA *101*, *Life Safety Code*.

4.10.5 Any door in a required means of egress from an area having an occupant load of 100 or more persons shall be permitted to be provided with a latch or lock only if it is panic hardware or fire exit hardware.

4.10.6 Means of egress shall be kept clear of obstructions and tripping hazards.

4.10.7 Emergency Instructions to Audience. When an audience is present, an announcement shall be made notifying the audience of the following:

(1) The location of exits to be used in case of fire or other emergency
(2) The means that will be used to notify the audience of fire or other emergency

4.11 Fire Protection.

4.11.1 Extinguishment Requirements.

4.11.1.1 Existing soundstages and existing approved production facilities equipped with automatic sprinkler systems shall maintain those systems in accordance with NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*.

4.11.1.2 A new soundstage or new approved production facility shall be equipped with an approved, supervised automatic sprinkler system.

4.11.1.3 The automatic sprinkler system required by 4.11.1.2 shall be installed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*, unless otherwise provided in 4.11.1.3.1 or 4.11.1.3.2.

4.11.1.3.1* The requirements of NFPA 13 prohibiting obstructions to sprinkler discharge shall not be applicable if approved mitigation is employed.

4.11.1.3.2* The requirements of NFPA 13 prohibiting obstructions to sprinkler discharge shall not be applicable if the building sprinkler system meets the design criteria for Extra Hazard, Group 2.

4.11.1.4 The automatic sprinkler system required by 4.11.1.2 shall be maintained in accordance with NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems*.

4.11.1.5 Portable fire extinguishers shall be installed and maintained in accordance with NFPA 10, *Standard for Portable Fire Extinguishers*.

4.11.2 Fire Alarm System. Fire alarm system notification appliances within soundstages and approved production facilities shall be permitted to be deactivated with the approval of the AHJ during videotaping, filming, or broadcasting of programs, provided the following conditions exist:

(1) In the event of alarm system activation, notification appliances shall activate at a location that is constantly attended during the videotaping, filming, or broadcasting of programs.
(2) The attendants of the location identified in 4.11.2(1) shall be provided with a means of communicating with the fire command center for the building, where one is provided, and with the occupants of the soundstage to initiate emergency action.
(3) Deactivation of notification appliances shall cause activation of a visual signal at an approved location, which shall remain illuminated while notification appliances on the soundstage are deactivated.
(4) The visual signal shall be identified by a sign that shall read, "When Illuminated, Soundstage Fire Alarm System Notification Appliances Are Deactivated."

4.12 Air Conditioning, Heating, and Ventilating. Air-conditioning, heating, and ventilating ductwork and related equipment shall be in good working order and in compliance with the requirements of the AHJ.

Chapter 5 Production Locations

5.1 General. This chapter shall apply to production locations.

5.2 Permits. A permit shall be obtained, unless waived by the AHJ, for any of the following activities:

(1)*Use of the site as a production location
(2) Use of pyrotechnic special effects
(3) Use of open flames
(4) Welding
(5) Use of flammable or combustible liquids or gases
(6) Use of aircraft
(7) Presence of motor vehicles within a building

5.3 Pyrotechnic Special Effects and Open Flames.

5.3.1 The use of pyrotechnic special effects and open flames shall be subject to the approval of the AHJ.

5.3.2 When an audience is present, NFPA 1126, *Standard for the Use of Pyrotechnics Before a Proximate Audience*, shall be used to regulate any pyrotechnic use.

5.3.3 When an audience is present, NFPA 160, *Standard for the Use of Flame Effects Before an Audience*, shall be used to regulate any flame effects use.

5.4 Standby Fire Personnel.

5.4.1 Pyrotechnics. Standby fire personnel shall be required for production locations where pyrotechnic special effects are used, unless otherwise waived by the AHJ.

5.4.2 Other Hazards. Where required by the AHJ, standby fire personnel shall be provided for hazardous operations other than pyrotechnic special effects.

5.5 Foamed Plastic Materials. Foamed plastic materials used for decorative purposes, scenery, sets, or props shall have a heat release rate not exceeding 100 kW where tested in accordance with UL 1975, *Standard for Fire Tests for Foamed Plastics Used for Decorative Purposes*, or where tested in accordance with NFPA 289, *Standard Method of Fire Test for Individual Fuel Packages*, using the 20 kW ignition source.

5.6 Smoking.

5.6.1 Smoking shall be prohibited in production location buildings unless otherwise provided in 5.6.2 or 5.6.3.

5.6.2 Smoking shall be permitted when it is a necessary part of a performance, and only when the smoker is a member of the cast.

5.6.3 Except where prohibited by the AHJ, smoking shall be permitted where all of the following conditions are met:

(1) The smoking area is outdoors.
(2) Hazardous materials are not present.
(3) Approved ash trays or receivers are provided.

5.7 Structural Loads.

5.7.1 Sets, scenery, and other equipment shall not impact the structural integrity of existing buildings.

5.7.2 Additional loads applied onto the building shall require the approval of the AHJ.

5.8 Electrical Requirements.

5.8.1 Electrical power connections made to the site electrical service shall be made by an approved electrician under permit from the AHJ.

5.8.2 Portable cables shall be positioned to allow for emergency egress as approved by the AHJ.

5.8.3* Auxiliary power cables supplied from mobile generators or adjacent buildings shall be permitted to be routed through fire-rated windows and doors with the approval of the AHJ.

5.8.4 Where power from both mobile generators and site electrical services are used to energize equipment in the same proximate location at production locations, grounds for the two systems shall be bonded in accordance with *NFPA 70, National Electrical Code.*

5.9* Fire Department Access. Fire department access shall be maintained as required by the AHJ.

5.10* Means of Egress. The production location shall be provided with means of egress appropriate for the intended use as approved by the AHJ.

5.11 Fire Protection.

5.11.1* Building areas used as production locations shall be designed, constructed, and maintained to protect the occupants not intimate with the initial fire development for the time needed to evacuate, relocate, or defend in place.

5.11.2 Where an automatic sprinkler system is provided for compliance with 5.11.1, the automatic sprinkler system shall be installed in accordance with NFPA 13, *Standard for the Installation of Sprinkler Systems*, unless otherwise provided in 5.11.4 or 5.11.5.

5.11.3 In any production location building protected by an existing automatic sprinkler system, where solid- or hard-ceiling sets or platforms are introduced and create an obstruction to sprinkler discharge, the provisions of 5.11.4 or 5.11.5 shall be met.

5.11.4* The requirements of NFPA 13, *Standard for the Installation of Sprinkler Systems*, prohibiting obstructions to sprinkler discharge shall not be applicable if approved mitigation is employed.

5.11.5* The requirements of NFPA 13, *Standard for the Installation of Sprinkler Systems*, prohibiting obstructions to sprinkler discharge shall not be applicable if the building sprinkler system meets the design criteria for Extra Hazard, Group 2.

5.11.6 Automatic sprinkler systems, where provided, shall be maintained in accordance with NFPA 25, *Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems.*

5.11.7 Portable fire extinguishers shall be provided as required by the AHJ.

5.11.8 Fire Hydrants and Fire Appliances. Hydrants, standpipes, and fire department connections (FDCs) shall not be obstructed, blocked, or rendered inoperable unless approved by the AHJ.

Chapter 6 Operating Features

6.1 Waste or Refuse. Waste or refuse shall not be allowed to accumulate in any area or in any manner that creates a fire hazard.

6.2 Flammable or Combustible Liquids.

6.2.1 The use, mixing, dispensing, and storage of flammable or combustible liquids shall be in accordance with the fire code as adopted by the AHJ and the following codes, as applicable, unless otherwise permitted by 6.2.2:

(1) NFPA 30, *Flammable and Combustible Liquids Code*
(2) NFPA 58, *Liquefied Petroleum Gas Code*

6.2.2 Approved flammable or combustible liquids and liquefied petroleum gases used for special effects shall be permitted.

6.3 Welding. Welding shall be in accordance with NFPA 51, *Standard for the Design and Installation of Oxygen–Fuel Gas Systems for Welding, Cutting, and Allied Processes*, and NFPA 51B, *Standard for Fire Prevention During Welding, Cutting, and Other Hot Work.*

6.4* Audience Life Safety. When an audience is present during productions, provisions for life safety and means of egress shall be subject to the approval of the AHJ.

6.5 Emergency Services Notification. The production company shall provide a procedure acceptable to the AHJ for notifying the public emergency services of emergency incidents.

Annex A Explanatory Material

Annex A is not a part of the requirements of this NFPA document but is included for informational purposes only. This annex contains explanatory material, numbered to correspond with the applicable text paragraphs.

A.1.1.1 The entertainment industry occasionally depicts actions, situations, equipment installations, or construction that are violations of recommended standards and codes but do not reflect actual entertainment industry safety practices.

A.2.1 The Motion Picture and Television Industry Committee recognizes that it is sometimes not practical to continually upgrade existing buildings or installations to comply with all the requirements of the referenced publications.

A.3.2.1 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

A.3.2.2 Authority Having Jurisdiction (AHJ). The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A.3.2.4 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A.4.2(8) An example of a *change of use* would be a soundstage with audience facilities for 50 persons being used for a preview party for 500 persons. An example of a *change of occupancy classification* would be a soundstage without audience facilities being used for a preview party for 500 persons.

A.4.3.1 Particular attention needs to be given to combustible materials used in close proximity to pyrotechnic and open-flame special effects. On-site verification of the fire retardant properties of set components, furnishings, props, and other combustible materials is essential to ensure the safety of pyrotechnic and open-flame special effects. The provisions of Section 4.5 address the need to render drapes, greens, foamed plastics, and other combustible materials fire retardant.

A comprehensive safety meeting should be conducted to define the intended scope of a special effect and establish appropriate safe areas. The safe areas need to be sized in consideration of the variable predictability of the materials used in the special effect. The safety meeting should include the participation of all persons who will be present during the special effect. The meeting discussion should also include consideration of the following:

(1) Conducting a test in an approved location of all devices and materials intended to be used in the special effect
(2) Excluding nonessential persons from the area of the effect until special effects personnel and a representative of the AHJ declare the area to be safe
(3) Evaluating the potential impact of the special effect on the uninvolved public
(4) Establishing an emergency plan that includes initial actions to take if the special effect exceeds its intended size, intensity, or duration
(5) Maintaining safe escape routes from the special effects area
(6) Developing methods of communication to be used during the special effect
(7) Identifying the individuals authorized to require that emergency actions be taken
(8) Specifying the licensing requirements for the individuals initiating the special effect
(9) Specifying the clothing to be worn by all special effects and safety personnel
(10) Evaluating the assignments and required abilities of all special effects and safety personnel
(11) Assigning the appropriate number of safety personnel to implement the plan
(12) Determining adequate and appropriate fire protection tailored to the materials used
(13) Establishing primary and backup methods of requesting additional fire suppression resources
(14) Identifying a definitive point when the special effect is complete

A.4.5.2(4) It is important that combustible drapes, drops, and similar materials exhibit adequate fire performance. The AHJ might be able to make a judgment of adequate fire performance without requiring testing of the materials.

A.4.5.2(5) Examples of interim measures that could be approved by the AHJ include, but are not limited to, the following:

(1) Providing a fire watch
(2) Removing the combustible materials at the end of the day's filming
(3) Keeping lighting and other heat-producing sources away from the combustible materials
(4) Providing baffles around heat-producing sources

A.4.8.2 This requirement does not prohibit the use of mobile generators for auxiliary power.

A.4.11.1.3.1 Paragraphs 4.11.1.3.1 and 4.11.1.3.2 recognize motion picture and television industry practices that require sets to change constantly and that sets are "temporary" construction not subject to building codes or standards. Solid ceilings that obstruct the stage sprinklers are "flown" (moved) in or out to permit special shooting angles or lighting requirements, often on a scene-by-scene basis. With temporary walls and ceilings, it would be impractical to install a sprinkler system in a constantly changing structure. Therefore, one or more of the following mitigation techniques should be used to compensate for the areas shielded from sprinkler spray by solid or hard ceilings or platforms:

(1) Approved and listed heat detectors or smoke detectors can be installed beneath such solid or hard ceilings in excess of 600 ft^2 (55.7 m^2) in area and platforms in excess of 600 ft^2 (55.7 m^2) in area and 3 ft (0.9 m) in height. Detectors should be connected to an approved and listed central, proprietary, or remote station service or to a local alarm that will provide an audible signal (i.e., a bell or horn) at a constantly attended location. The detector system, including the alarm panel, is defined as a portable system because it is intended to be reinstalled when platforms or sets are changed. The detectors that are secured to standard outlet boxes and the listed fire alarm panels can be temporarily supported by sets, platforms, or pedestals. Spacing of detectors should be per manufacturers' requirements.

(2) The ceiling can be positioned to allow for the operation of the building's automatic fire sprinkler system after videotaping, filming, or broadcasting of programs has been completed for the day.
(3) A fire watch should be provided when the set is not in use.
(4) No combustible materials should be stored under any platforms. Consideration should be given to secure such covered areas with screen wire or other materials that will permit visual inspection and emergency access.
(5) Approved/listed fire retardants can be applied beneath combustible platforms.
(6) Approved/listed fire retardants can be applied to scenery, props, framework and deck of combustible platforms, and the hard ceilings of combustible sets.

A.4.11.1.3.2 See A.4.11.1.3.1.

A.5.2(1) The AHJ might waive the production location permit provided the AHJ is notified that the site is to be used as a production location.

A.5.8.3 The AHJ might approve the routing of power cables through fire-rated windows or doors if standby fire personnel or other approved safeguards are provided during such periods.

A.5.9 The AHJ, when granting a permit to a production company to film on location, should consider the placement of the support equipment. Typically, the production support vehicles are numerous, and unregulated placement of these vehicles could impede emergency access or egress. Additionally, the types of support vehicles need to be arranged so that a hazardous operation (e.g., fueling or special effects) is distant from sources of ignition and crew gathering areas (e.g., catering locations). The location permit should include a plot plan so the AHJ can adequately assess potential problems.

A.5.10 Where a production company films *on location*, such activity might interfere with, or prevent, the normal use of the facility or area. As such, the facility being occupied as a production location is often used for a purpose different from that of its normal use. Where the production company filming causes the facility or area to curtail normal operations, the facility should not be required to meet the life safety provisions applicable to the normal occupancy. Rather, life safety features should be maintained consistent with provisions required for the temporary use. For example, consider a single story assembly occupancy building with occupant load of 600 persons that has three exits for compliance with the provision of NFPA *101*, *Life Safety Code*, that requires a minimum of three exits where the occupant load of a floor exceeds 500 persons. The assembly occupancy building is used as a production location for a total of 200 persons. The production crew presents, for approval of the AHJ, a plan to block off one of the three exits while maintaining compliance with the requirements for egress width, travel distance, common path of travel, and dead-end corridors. The AHJ approves the proposed means of egress as appropriate for the intended use as required by Section 5.10.

A.5.11.1 The phrase "intimate with the initial fire development" refers to the person(s) at the ignition source or first materials burning, not to all persons within the same room or area.

The occupant protection requirement of 5.11.1 is the same as that required for all occupancies by NFPA *101*, *Life Safety Code*. The activities associated with filming at a production location without an audience are characteristic of the occupancy classification of industrial occupancy. Industrial occupancies are not required by NFPA *101* to be sprinklered. The objective of protecting occupants not intimate with the initial fire development for the time needed to evacuate, relocate, or defend in place is accomplished for industrial occupancies by prescriptive provisions not dependent on sprinkler protection.

Where production location filming occurs in a building area not provided with the life safety systems required for industrial occupancies (e.g., in a tower with a single means of egress provided by an unenclosed stair), sprinklers, a fire alarm system, or other mitigation techniques acceptable to the AHJ will need to be employed for compliance with 5.11.1. Where sprinklers are provided, see 5.11.2 and 5.11.6.

A.5.11.4 See A.4.11.1.3.1.

A.5.11.5 See A.4.11.1.3.1.

A.6.4 Special attention should be focused on any possible obstructions to the means of egress. The means of egress and the marking of it might be confusing to the audience due to the numerous bright lights, scenery, video and film cameras, and other equipment in and around the soundstage.

NFPA®150

Standard on

Fire and Life Safety in Animal Housing Facilities

2016 Edition

This edition of NFPA 150, *Standard on Fire and Life Safety in Animal Housing Facilities*, was prepared by the Technical Committee on Animal Housing Facilities. It was issued by the Standards Council on May 26, 2015, with an effective date of June 15, 2015, and supersedes all previous editions.

This edition of NFPA 150 was approved as an American National Standard on June 15, 2015.

Origin and Development of NFPA 150

After a series of disastrous fires in racetrack stables in 1975, NFPA established the Committee on Firesafety in Racetrack Stables. This committee began its work in 1976 with the establishment of three working subcommittees covering construction, occupancy requirements, and fire protection. NFPA 150, *Standard on Firesafety in Racetrack Stables*, was first published in 1979. In the 1985 edition, minor changes were made to the standard that included the printing of Table 3 from NFPA 220, *Standard on Types of Building Construction*, in Appendix A. Changes to both the 1991 and 1995 editions consisted of editorial improvements and clarifications of the existing text.

The 2000 edition added a section on equivalency and essentially revised other portions of the text to reflect the *Manual of Style for NFPA Technical Committee Documents* for use of mandatory language.

In 2004, the scope of NFPA 150 expanded to include life and safety requirements for both humans and animals in all types of animal housing facilities. In July of 2004, the Standards Council approved the expansion and changed the name of the document to *Standard on Fire and Life Safety in Animal Housing Facilities*. The expanded NFPA 150 provided better guidance to authorities having jurisdiction by addressing all types of animal housing facilities and made possible the consistent treatment of such facilities from jurisdiction to jurisdiction.

The 2009 edition included several updates related primarily to the referenced codes and standards and to some of the extracted text. A new provision allowing the use of the room-corner test from NFPA 286, *Standard Methods of Fire Tests for Evaluating Contribution of Wall and Ceiling Interior Finish to Room Fire Growth,* was introduced to allow an alternative test protocol to evaluate interior finish materials. These refinements continued and a new chapter on performance-based design approaches was added for the 2013 edition. Other changes for that edition included supplemental provisions for the built-in fire protection systems that are mandated by the standard.

Changes for the 2016 edition include several clarifications and additions, including scoping criteria with regard to how the standard should be applied to existing buildings, classification of all agricultural animals in the Category B scheme for protection purposes, and a provision that extends automatic sprinkler and smoke control systems into all facilities that board or house horses.

This list represents the membership at the time the Committee was balloted on the final text of this edition. Since that time, changes in the membership may have occurred. A key to classifications is found at the back of the document.

NOTE: Membership on a committee shall not in and of itself constitute an endorsement of the Association or any document developed by the committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on the loss of animal and human life and property from fire in animal housing facilities, including, but not limited to the following: barns; stables; kennels; animal shelters; animal hospitals; veterinary facilities; zoos, special amusement parks; agricultural facilities; laboratories; and racetrack stable and kennel areas including those stable and kennel areas, barns, and associated buildings at state, county, and local fairgrounds. This Committee does not cover building code or life safety code requirements that are handled by other committees.

Standard on

Fire and Life Safety in Animal Housing Facilities

2016 Edition

IMPORTANT NOTE: This NFPA document is made available for use subject to important notices and legal disclaimers. These notices and disclaimers appear in all publications containing this document and may be found under the heading "Important Notices and Disclaimers Concerning NFPA Documents." They can also be obtained on request from NFPA or viewed at www.nfpa.org/disclaimers.

UPDATES, ALERTS, AND FUTURE EDITIONS: New editions of NFPA codes, standards, recommended practices, and guides (i.e., NFPA Standards) are released on scheduled revision cycles. This edition may be superseded by a later one, or it may be amended outside of its scheduled revision cycle through the issuance of Tentative Interim Amendments (TIAs). An official NFPA Standard at any point in time consists of the current edition of the document, together with any TIAs and Errata in effect. To verify that this document is the current edition or to determine if it has been amended by any TIAs or Errata, please consult the National Fire Codes® Subscription Service or visit the Document Information (DocInfo) pages on the NFPA website at www.nfpa.org/docinfo. In addition to TIAs and Errata, the DocInfo pages also include the option to sign up for Alerts for each document and to be involved in the development of the next edition.

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates that explanatory material on the paragraph can be found in Annex A.

A reference in brackets [ ] following a section or paragraph indicates material that has been extracted from another NFPA document. As an aid to the user, the complete title and edition of the source documents for extracts in mandatory sections of the document are given in Chapter 2 and those for extracts in informational sections are given in Annex C. Extracted text may be edited for consistency and style and may include the revision of internal paragraph references and other references as appropriate. Requests for interpretations or revisions of extracted text shall be sent to the technical committee responsible for the source document.

Information on referenced publications can be found in Chapter 2 and Annex C.

Chapter 1 Administration

1.1 Scope.

1.1.1* This standard shall provide the minimum requirements for the design, construction, fire protection, and classification of animal housing facilities.

1.1.2 Animal housing facilities shall be designed, constructed, and maintained in accordance with the adopted building, fire, and life safety codes and the requirements herein.

1.1.3 Where requirements of this standard differ from the adopted fire prevention, life safety, and building codes, the requirements of this standard shall govern the protection of the animal occupants and animal handlers.

1.2 Purpose. The purpose of this standard shall be to prevent the loss of animal life, human life, and property from fire or other emergencies by providing the minimum requirements for the design, construction, operation, and maintenance of facilities where animals are housed, including but not limited to rest, feed, work, exercise, and production areas.

1.3 Application.

1.3.1* This standard shall apply to animal housing facilities that are subject to local, state, or federal licensing or permitting requirements, including but not limited to the following:

(1) Barns and stables
(2) Kennels
(3) Racetrack stable/kennel areas, including those stable/kennel areas, barns, and associated buildings at state, county, and local fairgrounds
(4) Animal shelters
(5) Animal hospitals and veterinary facilities
(6) Zoos and special amusement parks
(7) Laboratories
(8) Agricultural facilities
(9) Mercantile or business occupancies with animals

1.3.2 This standard shall apply to new animal housing facilities.

1.3.3* This standard shall also apply to existing facilities where any one of the following conditions applies:

(1) A change of use or occupancy classification occurs where animals are introduced.
(2) A change is made in the subclassification or category of the animals housed.
(3) An extensive modification, reconstruction, or addition is made.
(4) A building or structure with an animal housing facility is relocated.
(5) A building with an animal housing facility is considered damaged, unsafe, or a fire hazard.
(6) A property line that affects compliance with any provision of this standard is created or relocated.

1.3.4* This standard shall apply to temporary structures housing animals solely for the purposes of developing a disaster/emergency management program in accordance with 4.3.4.

1.4 Retroactivity. The provisions of this standard provide an acceptable degree of protection from the hazards addressed in this standard at the time the standard was issued.

1.4.1 Unless otherwise specified, the provisions of this standard shall not apply to facilities, equipment, structures, or installations that existed or were approved for construction or installation prior to the effective date of the standard. Where specified, the provisions of this standard shall be retroactive.

1.4.2 This standard shall apply to existing installations that are determined by the AHJ to constitute imminent danger to animal occupant or animal handler safety.

1.4.3 The retroactive requirements of this standard shall be permitted to be modified if their application clearly would be impractical in the judgment of the authority having jurisdiction, and only where it is clearly evident that a reasonable degree of safety is provided.

1.5 Equivalency. Nothing in this standard is intended to prevent the use of systems, methods, or devices of equivalent or superior quality, strength, fire resistance, effectiveness, durability, and safety over those prescribed by this standard.

1.5.1 Technical documentation shall be submitted to the authority having jurisdiction to demonstrate equivalency.

1.5.2 The system, method, or device shall be approved for the intended purpose by the authority having jurisdiction.

1.5.3 Alternative systems, methods, or devices approved as equivalent by the authority having jurisdiction shall be recognized as being in compliance with this standard.

1.6 Units.

1.6.1 SI Units. Metric units in this standard are in accordance with the modernized metric system known as the International System of Units (SI).

1.6.2 Primary and Equivalent Values. If a value for a measurement as given in this standard is followed by an equivalent value in other units, the first stated value shall be regarded as the requirement. A given equivalent value might be approximate.

1.7 Enforcement. This standard shall be administered and enforced by the authority having jurisdiction designated by the governing authority. *(See Annex B for sample wording for enabling legislation.)*

Chapter 2 Referenced Publications

2.1 General. The documents or portions thereof listed in this chapter are referenced within this standard and shall be considered part of the requirements of this document.

2.2 NFPA Publications. National Fire Protection Association, 1 Batterymarch Park, Quincy, MA 02169-7471.

NFPA 1, *Fire Code,* 2015 edition.
NFPA 10, *Standard for Portable Fire Extinguishers,* 2013 edition.
NFPA 13, *Standard for the Installation of Sprinkler Systems,* 2016 edition.
NFPA 31, *Standard for the Installation of Oil-Burning Equipment,* 2011 edition.

NFPA 5000®, Building Construction and Safety Code®, 2015 edition.

Chapter 3 Definitions

3.1 General. The definitions contained in this chapter shall apply to the terms used in this standard. Where terms are not defined in this chapter or within another chapter, they shall be defined using their ordinarily accepted meanings within the context in which they are used. *Merriam-Webster's Collegiate Dictionary,* 11th edition, shall be the source for the ordinarily accepted meaning.

3.2 NFPA Official Definitions.

3.2.1* Approved. Acceptable to the authority having jurisdiction.

3.2.2* Authority Having Jurisdiction (AHJ). An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

3.2.3 Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

3.2.4* Listed. Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

3.2.5 Shall. Indicates a mandatory requirement.

3.2.6 Should. Indicates a recommendation or that which is advised but not required.

3.2.7 Standard. An NFPA Standard, the main text of which contains only mandatory provisions using the word "shall" to indicate requirements and that is in a form generally suitable for mandatory reference by another standard or code or for adoption into law. Nonmandatory provisions are not to be considered a part of the requirements of a standard and shall be located in an appendix, annex, footnote, informational note, or other means as permitted in the NFPA Manuals of Style. When used in a generic sense, such as in the phrase "standards development process" or "standards development activities," the term "standards" includes all NFPA Standards, including Codes, Standards, Recommended Practices, and Guides.

3.3 General Definitions.

3.3.1 Addition. An increase in the building area, aggregate floor area, building height, or number of stories of a structure. [**5000,** 2015]

3.3.2 Animal. For the purposes of this standard, an air-breathing vertebrate.

3.3.2.1* ***Confined Animals.*** Animals housed such that human intervention is required for their release and evacuation in case of emergency.

3.3.3* Animal Handler. A person responsible for the handling, grooming, and care of confined animals, or reasonably expected to assist in their handling and evacuation in case of emergency.

3.3.4* Animal Housing Facility. Area of a building or structure, including interior and adjacent exterior spaces, where animals are fed, rested, worked, exercised, treated, exhibited, or used for production.

3.3.5 Building Height. The vertical distance from the grade plane to the average elevation of the highest roof surface. [**5000,** 2015]

3.3.6 Cage. A box or enclosure from which an animal or animals cannot normally escape without human intervention.

3.3.7 Confined Animals. See 3.3.2.1.

3.3.8 Feed Room. See 3.3.20.1.

3.3.9 Fire Resistance Rating. The time in minutes or hours that materials or assemblies have withstood a fire exposure, as established in accordance with the tests or methods based on tests prescribed by this standard. [**5000,** 2015]

3.3.10 General Public. People who do not have an intimate knowledge of the layout of the building or structure, or the general behavior of the animals at the facility, and are not intended personnel.

3.3.11 Halter. A piece of equipment, composed of rope or straps and buckles, that fits securely around the head of an animal such as a horse or cow, used in handling and leading animals from place to place.

3.3.12 Intended Personnel. People working in the animal housing facility with an intimate knowledge of the layout of the building or structure and the general behavior of the animals at the facility, such as employees or students, who are not considered the general public.

3.3.13 Lead. A rope, chain, or strap of suitable length with a clasp at one end used for handling and leading animals by a halter, collar, or harness.

3.3.14 Mechanical Equipment Room. See 3.3.20.2.

3.3.15 Modification. The reconfiguration of any space, the addition or elimination of any door or window, the addition or elimination of load-bearing elements, the reconfiguration or extension of any system, or the installation of any additional equipment. [**5000,** 2015]

3.3.16 Occupancy. The purpose for which a building or other structure, or part thereof, is used or intended to be used. [**ASCE/SEI 7:**1.2]

3.3.17* Protection. A device, material, or system that provides a specified level of safety to achieve a desired outcome.

3.3.18 Reconstruction. The reconfiguration of a space that affects an exit, or a corridor shared by more than a single tenant; or reconfiguration of space such that the rehabilitation work area is not permitted to be occupied because existing means of egress and fire protection systems, or their equivalent, are not in place or continuously maintained. [**5000,** 2015]

3.3.19 Renovation. The replacement in kind, strengthening, or upgrading of elements, materials, equipment, or fixtures that does not result in a reconfiguration of the building or spaces within. [**5000,** 2015]

3.3.20 Room.

3.3.20.1 ***Feed Room.*** Room used to store feed and feed supplies for animals.

3.3.20.2 ***Mechanical Equipment Room.*** Room that contains mechanical, electrical, air conditioning, or other equipment.

3.3.20.3 ***Storage Room.*** Enclosed room within a building containing tack and equipment used for animal handling, capture, restraint, grooming, training, care, and upkeep of the animal facility.

3.3.20.4 ***Tack Room.*** A storage area for tack and stable equipment.

3.3.21 Stall. A room or compartment that normally houses one or more animals.

3.3.22 Storage Room. See 3.3.20.3.

3.3.23 Tack. Stable gear; also harnesses, bridles, saddles, and other accessories used in riding or driving horses.

3.3.24 Tack Room. See 3.3.20.4.

3.3.25 Trainer. A person responsible for the care and training of animals.

Chapter 4 General Requirements

4.1* Goals and Objectives.

4.1.1* Goals. The primary goals of this standard shall be safety and facility usability for both human and animal occupants, including property protection as it relates to the primary goals.

4.1.2* Objectives. To achieve the goals stated in 4.1.1, the goals and objectives of 4.1.3 and 4.1.4 shall be satisfied.

4.1.3 Safety. The intent of the safety goal of this standard shall be to reduce the probability of injury or death to both animal and human occupants from fire, similar emergencies, and facility use.

4.1.3.1 Safety from Fire.

4.1.3.1.1* Safety-from-Fire Goals. The fire safety goals of this standard shall be as follows:

(1) To provide an environment for human occupants inside an animal housing facility that is reasonably safe from fire and similar emergencies
(2) To provide an environment for animal occupants inside or adjacent to a structure that is reasonably safe from fire and similar emergencies
(3) To provide reasonable safety for fire fighters and emergency responders during search and rescue operations for animal and human occupants
(4) To attempt to minimize loss of property and interruption of facility operations from fire and similar emergencies

4.1.3.1.2 Safety-from-Fire Objectives.

4.1.3.1.2.1 Facilities shall be designed and constructed to protect human and animal occupants not intimate with the initial fire development for the time needed to evacuate, relocate, or defend in place.

4.1.3.1.2.2* Facilities shall be designed and constructed to provide reasonable safety for fire fighters and emergency responders during search and rescue operations for animal and human occupants.

4.1.3.1.2.3 Facilities shall be designed and constructed to provide reasonable access to the structure for emergency responders.

4.1.3.1.2.4 Facilities shall be designed and constructed to reasonably protect adjacent persons, animals, and structures from injury, death, or substantial damage as a result of a fire.

4.1.3.2 Safety During Facility Use.

4.1.3.2.1* Safety-During-Facility-Use Goal. The safety-during-facility-use goal of this standard shall be to provide an environment for both the human and animal occupants of the facility that is reasonably safe during the normal use of the facility.

4.1.3.2.2 Safety-During-Facility-Use Objectives.

4.1.3.2.2.1 Facilities shall be designed and constructed to provide for reasonably safe animal and crowd movement during emergency and nonemergency conditions.

4.1.3.2.2.2 Facilities shall be designed and constructed to provide reasonable safety for animal and human occupants and workers during construction and demolition.

4.1.3.2.2.3* Facilities shall be designed and constructed to provide reasonable and appropriate notification to occupants during emergency situations.

4.1.3.2.2.4 Facilities shall be designed and constructed to provide reasonable signage to identify hazards, means of egress, and other building safety features.

4.1.4 Usability Goal. The intent of the usability goal of this standard shall be to ensure that the facility is capable of functioning at the level for which it was designed.

4.1.4.1 Function.

4.1.4.1.1* Function Goal. The intent of the function goal of this standard shall be to ensure that a facility and its systems, features, and construction, throughout its life, provide reasonable capability of operation to satisfy the other goals of this standard.

4.1.4.1.2* Function Objective. Facilities shall be designed and constructed to provide reasonable assurance that its systems, features, and construction are capable of performing their intended use to satisfy the objectives of this standard.

4.2 Fundamental Fire and Life Safety Requirements.

4.2.1 Multiple Safeguards.

4.2.1.1 The design of every facility intended for animal and human occupancy shall be such that reliance for property protection and safety to life does not depend solely on any single safeguard.

4.2.1.2 Additional safeguard(s) shall be provided for property protection and life safety in case any single safeguard is ineffective due to inappropriate animal or human actions, building failure, or system failure.

4.2.2 Appropriateness of Safeguards. Every facility shall be provided with means of egress and other fire and life safety safeguards of the kinds, numbers, locations, and capacities appropriate to the individual facility, with due regard to the following:

(1) Character of the occupancy, including fire load
(2) Characteristics and capabilities of both human and animal occupants and their responses to fire protection safeguards
(3) Number of animals and persons exposed
(4) Fire protection available
(5) Height and type of construction of the facility
(6) Other factors necessary to provide animal and human occupants with a reasonable degree of safety
(7) Other factors necessary to protect the facility and contents from unacceptable damage

4.2.3 Means of Egress. The minimum number of means of egress for human and animal occupants shall be in accordance with Chapter 8.

4.2.4* Occupant Notification. In every facility of such size, arrangement, or occupancy that a fire itself might not provide adequate occupant warning, fire alarm systems shall be provided where necessary to warn occupants of the existence of fire.

4.2.5 System Design and Installation. Any fire protection system, building service equipment, feature of protection, or safeguard provided for fire and life safety shall be designed, installed, and approved in accordance with applicable NFPA codes and standards.

4.2.6 Limiting Fire Spread.

4.2.6.1 The interior surfaces of the facility shall not contribute to an unacceptable rate and magnitude of fire spread and generation of heat and smoke.

4.2.6.2 The construction of concealed spaces shall not contribute to an unacceptable rate of the spread of fire, hot gases, and smoke to areas of the facility remote from the fire source and shall limit their spread beyond the immediate area of the origin of the fire.

4.2.6.3 The facility shall be compartmented, as appropriate, by walls and floors, including their associated openings with proper closures, to limit the spread of fire, hot gases, and smoke to an acceptable area beyond the immediate area of fire origin.

4.2.7 Structural Integrity. The facility's structural members and assemblies shall be provided with the required degree of fire resistance to limit structural damage, damage to the building and its contents, and damage to adjacent buildings and property.

4.3 General Requirements.

4.3.1 Authority Having Jurisdiction.

4.3.1.1 The authority having jurisdiction (AHJ) shall determine whether the provisions of this standard are met.

4.3.1.2 Where it is evident that a reasonable degree of safety is provided, any requirement shall be permitted to be modified if, in the judgment of the AHJ, its application would be hazardous under normal occupancy conditions.

4.3.1.3* Where it is evident that special circumstances not specifically addressed in this standard exist in the design, construction, use, or operation of the facility, the AHJ shall be permitted to require additional safeguards such that a reasonable degree of safety is provided.

4.3.2 Provisions in Excess of Standard Requirements. Nothing in this standard shall be construed to prohibit a superior type of building construction, an additional means of egress, or an otherwise safer condition than that specified by the minimum requirements of this standard.

4.3.3 Maintenance and Testing.

4.3.3.1 Where any device, equipment, system, condition, arrangement, or level of protection, or any other feature, is required for compliance with the provisions of this standard, such device, equipment, system, condition, arrangement, level of protection, or other feature shall thereafter be continuously maintained in accordance with applicable NFPA requirements or as directed by the AHJ.

4.3.3.2 Equipment requiring periodic testing or operation to ensure its maintenance shall be tested or operated as specified elsewhere in this standard or as directed by the AHJ.

4.3.3.3 Maintenance and testing shall be under the supervision of a responsible person who shall ensure that testing and maintenance are made at specified intervals in accordance with applicable NFPA standards or as directed by the AHJ.

4.3.4 Disaster/Emergency Management Program.

4.3.4.1 General. Disaster/emergency management programs shall be required in all animal housing facilities to protect and ensure the safety of the animal and human occupants during fire or other similar emergencies.

4.3.4.2 Program Requirements.

4.3.4.2.1* Disaster/emergency management programs shall be developed in accordance with *NFPA 1600* and shall include the procedures for reporting emergencies; the occupant and staff response to emergencies; the design and conduct of disaster/emergency drills; the type and coverage of building fire protection systems; and other items required by the AHJ.

4.3.4.2.2 Required disaster/emergency management programs shall be submitted to the AHJ for review and approval.

4.3.4.2.3 Disaster/emergency management programs shall be reviewed and updated annually.

4.3.4.2.4 Revised plans shall be submitted for review and updates shall be provided whenever changes are made in the occupancy or physical arrangement of the building or fire protection systems or features.

4.3.4.2.5 Floor plans shall be provided to the AHJ, as requested.

4.3.4.2.6 In accordance with the disaster/emergency management program, equipment designated as necessary for the evacuation or relocation of animals shall be readily accessible at all times.

4.3.5* Disaster/Emergency Drills.

4.3.5.1 Disaster/emergency drills conforming to the provisions of this standard shall be conducted in cooperation with the local authorities and as specified by this standard or by the AHJ.

4.3.5.2 Drill Frequency.

4.3.5.2.1 Where required by this standard or the AHJ, disaster/emergency drills shall be held to familiarize occupants with the drill procedure and to establish conduct of the drill as a matter of routine.

4.3.5.2.2* Disaster/emergency drills shall include procedures to ensure that all persons subject to the drill participate.

Chapter 5 Performance-Based Design Option

5.1* General Requirements.

5.1.1 Application. The requirements of this chapter shall apply to buildings or structures, portions of buildings or structures, or building systems designed in accordance with the performance-based option permitted by Section 4.3.

5.1.2 Goals and Objectives. The performance-based design shall meet the goals and objectives of Section 4.1.

5.1.3* Independent Review. The authority having jurisdiction shall be permitted to require an approved, independent third party to review the proposed design and provide an evaluation of the design to the authority having jurisdiction at the expense of the owner.

5.1.4 Sources of Data. Data sources shall be identified and documented for each input data requirement that must be met using a source other than a design scenario, an assumption, or a building design specification. The degree of conservatism reflected in such data shall be specified, and a justification for the source shall be provided.

5.1.5* Final Determination. The authority having jurisdiction shall make the final determination as to whether the performance objectives have been met.

5.1.6* Maintenance of Design Features.

5.1.6.1 The design features required for the building to continue to meet the performance goals and objectives of this standard shall be maintained for the life of the building. Such performance goals and objectives shall include complying with all documented assumptions and design specifications. Any variations shall require the approval of the authority having jurisdiction prior to the actual change.

5.1.6.2 Whenever or wherever any device, equipment, system, condition, arrangement, level of protection, or other feature is required to meet the goals, objectives, or performance criteria of this standard, approved procedures for the operation and maintenance of such device, equipment, system, condition, arrangement, level of protection, or other feature shall be prepared, and an approved system of inspection, maintenance, and testing shall be included in an operations and maintenance manual developed as part of the performance-based design.

5.1.7 Special Definitions. See Section 3.3.

5.2 Safety-from-Fire Goals.

5.2.1 The fire safety goals of this standard shall be as follows:

(1) To provide an environment for human occupants inside an animal housing facility that is reasonably safe from fire and similar emergencies
(2) To provide an environment for animal occupants inside or adjacent to a structure that is reasonably safe from fire and similar emergencies
(3) To provide reasonable safety for fire fighters and emergency responders during search and rescue operations for animal and human occupants
(4) To attempt to minimize loss of property and interruption of facility operations from fire and similar emergencies

5.2.2 Safety-from-Fire Objectives.

5.2.2.1 Facilities shall be designed and constructed to protect human and animal occupants not intimate with the initial fire development for the time needed to evacuate, relocate, or defend in place.

5.2.2.2* Facilities shall be designed and constructed to provide reasonable safety for fire fighters and emergency responders during search and rescue operations for animal and human occupants.

5.2.2.3 Facilities shall be designed and constructed to provide reasonable access to the structure for emergency responders.

5.2.2.4 Facilities shall be designed and constructed to reasonably protect adjacent persons, animals, and structures from injury, death, or substantial damage as a result of a fire.

5.2.3 Safety During Facility Use.

5.2.3.1* Safety-During-Facility-Use Goal. The safety-during-facility-use goal of this standard shall be to provide an environment for both the human and animal occupants of the facility that is reasonably safe during the normal use of the facility.

5.2.3.2 Safety-During-Facility-Use Objectives.

5.2.3.2.1 Facilities shall be designed and constructed to provide for reasonably safe animal and crowd movement during emergency and nonemergency conditions.

5.2.3.2.2 Facilities shall be designed and constructed to provide reasonable safety for animal and human occupants and workers during construction and demolition.

5.2.3.2.3* Facilities shall be designed and constructed to provide reasonable and appropriate notification to occupants during emergency situations.

5.2.3.2.4 Facilities shall be designed and constructed to provide reasonable signage to identify hazards, means of egress, and other building safety features.

5.2.3.3 Glass or other similar frangible construction material shall be installed in such a manner that, if occupants come into contact with such material, one of the following occurs:

(1) The material resists impact without breaking.
(2) The material breaks in such a manner that it does not cause injury.
(3) The material is protected from occupant impact.

5.2.4 Uncontrolled Moisture.

5.2.4.1 Where critical to the operation and use of the animal housing facility, uncontrolled moisture shall be controlled in accordance with 5.2.4.1.1 through 5.2.4.1.3.

5.2.4.1.1 The exterior envelope of the building shall be designed to control the entry of precipitation into the building.

5.2.4.1.2 The exterior walls, attics, crawl spaces, and other concealed or enclosed building elements that constitute the building envelope shall be designed to control the accumulation of water vapor or its condensation in such quantities and physical state that contact of water vapor or its condensation with the building insulation or building materials will not result in conditions that adversely affect the health of the building occupants.

5.2.4.1.3 Building materials located in areas within the building that are subject to exposure from water discharges or leaks in quantities and durations that cause exterior moisture to accumulate for extended periods of time, thus resulting in conditions that adversely affect the health of the building occupants, shall be designed to control penetration of, or direct contact with, water or shall be protected from such exposure.

5.3 Retained Prescriptive Requirements. The design shall comply with the requirements of Section 5.3 in addition to the performance criteria of Section 5.2 and the methods of Sections 5.4 through 5.8.

5.3.1 Systems and Features. All fire protection systems and features of the building shall comply with applicable NFPA standards for those systems and features.

5.3.2 Means of Egress. Means of egress shall comply with Chapter 8.

5.4* Performance-Based Design Characteristics and Assumptions.

5.4.1 General.

5.4.1.1 Design characteristics and assumptions used in the performance-based design shall be clearly stated and shown to be realistic and sustainable.

5.4.1.2 Each design characteristic and assumption used in the design shall be accurately translated into input data specifications, as appropriate for the calculation method or model to be used.

5.4.1.3 Design characteristics and assumptions that the design analyses do not explicitly address or incorporate and that are, therefore, omitted from input data specifications shall be identified, and a sensitivity analysis of the consequences of that omission shall be performed.

5.4.1.4 Design characteristics and assumptions modified in input data specifications, due to limitations in test methods or other data-generation procedures, shall be identified, and a sensitivity analysis of the consequences of the modification shall be performed.

5.4.1.5* The design shall not include mutually inconsistent characteristics, assumptions, or statements of conditions.

5.4.2 Building Characteristics and Assumptions.

5.4.2.1* Characteristics of the building or its contents, equipment, layout, or operations that are not inherent in the design specifications, but that affect occupant or building behavior or the rate of hazard development, shall be explicitly identified.

5.4.2.2* The performance of building systems and features shall reflect the documented performance and reliability of the components of those systems or features, unless design specifications are incorporated to modify the expected performance.

5.4.3 Occupant Characteristics and Assumptions.

5.4.3.1* General. The selection of occupant characteristics to be used in the design calculations shall be approved by the authority having jurisdiction and shall provide an accurate reflection of the expected population of building users.

5.4.3.2 Occupant Profile. Occupant characteristics shall represent the normal occupant profile, unless design specifications are used to modify the expected occupant features.

5.4.3.3 Response Characteristics. The basic response characteristics of sensibility, reactivity, mobility, and susceptibility shall be considered. Such consideration shall include the expected distribution of characteristics of a population appropriate to the use of the building. The source of data for these characteristics shall be documented.

5.4.3.4 Location. It shall be assumed that, in every normally occupied room or area, at least one occupant shall be located at the most remote point from the exits.

5.4.3.5* Number of Occupants. The design shall be based on the maximum number of occupants that every occupied room or area is expected to contain. Where success or failure of the design is contingent on a specified maximum number of occupants, operational controls shall be used to ensure that a greater number of occupants could not be expected to be present.

5.4.3.6* Staff Assistance. In those occupancies where staff assistance is required to ensure the safety of other occupants, such trained assistance shall be provided. The ability of trained employees to be included as part of the building safety system shall be identified and documented.

5.4.4 Emergency Response Personnel Characteristics and Assumptions.

5.4.4.1 Nongovernmental emergency response personnel shall not be relied upon in the performance design, unless they are under the continuous and direct control of the building owner or occupant. Emergency response personnel of the governmental agency legally responsible for providing emergency responders to the local jurisdiction shall be permitted to be relied upon in the performance design when approved by the governmental agency.

5.4.4.2 Design characteristics and assumptions related to the availability, speed of response, effectiveness, roles, and other characteristics of emergency response personnel shall be specified, estimated, or characterized sufficiently for evaluation of the design.

5.5* Design Scenarios.

5.5.1 General.

5.5.1.1 The proposed design shall be considered to meet the goals and objectives if it achieves the performance criteria for each required design scenario. The authority having jurisdiction shall approve the parameters involved with design scenarios.

5.5.1.2 Design scenarios shall be evaluated for each required scenario using a method acceptable to the authority having jurisdiction and appropriate for the conditions. Each scenario shall be as challenging and realistic as any that could realistically occur in the building.

5.6 Evaluation of Proposed Designs.

5.6.1 General. A proposed design's performance shall be assessed relative to each performance objective in Section 4.1 and each applicable scenario in Section 5.5, with the assessment conducted through the use of appropriate calculation methods. The authority having jurisdiction shall approve the choice of assessment methods.

5.6.2 Use. The design professional shall use the assessment methods to demonstrate that the proposed design will achieve the goals and objectives for each scenario, as measured by the performance criteria in light of the safety margins and uncertainty analysis, given the assumptions.

5.6.3 Input Data.

5.6.3.1 Data. Input data for computer fire models shall be obtained in accordance with ASTM E1591, *Standard Guide for Obtaining Data for Deterministic Fire Models*. Data for use in analytical models that are not computer-based fire models shall be obtained using appropriate measurement, recording, and storage techniques to ensure the applicability of the data to the analytical method being used.

5.6.3.2 Data Requirements. A complete listing of input data requirements for all models, engineering methods, and other calculation or verification methods required or proposed as part of the performance-based design shall be provided.

5.6.3.3 Uncertainty and Conservatism of Data. Uncertainty in input data shall be analyzed and, as determined appropriate by the authority having jurisdiction, addressed through the use of conservative values.

5.6.4 Output Data. The assessment methods used shall accurately and appropriately produce the required output data from input data based on the design specifications, assumptions, and scenarios.

5.6.5 Validity. Evidence shall be provided confirming that the assessment methods are valid and appropriate for the proposed building, use, and conditions.

5.7 Safety Factors. Approved safety factors shall be included in the design methods and calculations to reflect uncertainty in the assumptions, data, and other factors associated with the performance-based design.

5.8 Documentation Requirements.

5.8.1* General. All aspects of the design, including those described in 5.8.2 through 5.8.14, shall be documented. The format and content of the documentation shall be acceptable to the authority having jurisdiction.

5.8.2 Technical References and Resources. The authority having jurisdiction shall be provided with sufficient documentation to support the validity, accuracy, relevance, and precision of the proposed methods. The engineering standards, calculation methods, and other forms of scientific information provided shall be appropriate for the particular application and methodologies used.

5.8.3 Building Design Specifications. All details of the proposed building design that affect the ability of the building to meet the stated goals and objectives shall be documented.

5.8.4 Performance Criteria. Performance criteria, with sources, shall be documented.

5.8.5 Occupant Characteristics. Assumptions about occupant characteristics shall be documented.

5.8.6 Design Scenarios. Descriptions of design hazards scenarios shall be documented.

5.8.7 Input Data. Input data to models and assessment methods, including sensitivity analysis, shall be documented.

5.8.8 Output Data. Output data from models and assessment methods, including sensitivity analysis, shall be documented.

5.8.9 Safety Factors. The safety factors utilized shall be documented.

5.8.10 Prescriptive Requirements. Retained prescriptive requirements shall be documented.

5.8.11* Modeling Feature.

5.8.11.1 Assumptions made by the model user and the description of the models and methods used, including known limitations, shall be documented.

5.8.11.2 Documentation shall be provided verifying that the assessment methods have been used validly and appropriately to address the design specifications, assumptions, and scenarios.

5.8.12 Evidence of Modeler Capability. The design team's relevant experience with the models, test methods, databases, and other assessment methods used in the performance-based design proposal shall be documented.

5.8.13 Performance Evaluation. The performance evaluation summary shall be documented.

5.8.14 Use of Performance-Based Design Option. Design proposals shall include documentation that provides anyone involved in ownership or management of the building with notification of the following:

(1) The building was approved as a performance-based design with certain specified design criteria and assumptions.
(2) Any remodeling, modification, renovation, change in use, or change in the established assumptions is to be reevaluated and reapproved.

Chapter 6 Subclassification of Animal Housing Facilities and Categorization of Animals

6.1 General.

6.1.1* Occupancy Classification. The general occupancy classification of a facility housing animals shall be determined in accordance with *NFPA 5000*, Chapter 6, or NFPA *101*, Chapter 6.

6.1.2 Occupancy Separations. The separations required between different occupancies shall be in accordance with *NFPA 5000*, Chapter 6, or NFPA *101*, Chapter 6.

6.2 Animal Housing Facility Subclassifications.

6.2.1 The occupancy of a facility housing animals shall be subclassified in accordance with this section.

6.2.1.1* Class 1 Facility. A Class 1 facility shall be an area of a building housing animals with no general public access.

6.2.1.2* Class 2 Facility. A Class 2 facility shall be an area of a building housing animals with restricted general public access.

6.2.1.3* Class 3 Facility. A Class 3 facility shall be an area of a building housing animals with regular general public access.

6.2.2 Animal housing facility subclassifications shall be subject to the ruling of the AHJ where there is a question of classification.

6.2.3 Types of Subclassifications.

6.2.3.1 Multiple Subclassification. A multiple subclassification facility shall be a facility in which two or more subclasses of animal housing facilities exist.

6.2.3.2 Mixed Subclassification. A mixed subclassification facility shall be a multiple subclassification facility where the subclassifications are intermingled.

6.2.3.3 Separated Subclassification. A separated subclassification facility shall be a multiple subclassification facility where the subclassifications are separated by fire barriers in accordance with NFPA *101* or *NFPA 5000* rated assemblies.

6.2.4 Multiple Subclassification.

6.2.4.1* Multiple subclassifications *(see 6.2.3)* shall comply with the requirements of one of the following:

(1) Mixed subclassification requirements *(see 6.2.5)*
(2) Separated subclassification requirements *(see 6.2.6)*

6.2.4.2* Where minor accessory subclassifications do not occupy more than 25 percent of the area of any story of a facility, the principal use of the facility shall determine the subclassification.

6.2.5 Mixed Subclassification.

6.2.5.1 Each portion of the facility shall be subclassified as to its use in accordance with 6.2.1.

6.2.5.2 The means of egress, type of construction, protection, and other safeguards in the facility shall comply with the most restrictive fire and life safety requirements of the subclassifications involved.

6.2.6 Separated Subclassification.

6.2.6.1 Where separated subclassifications are provided, each part of the structure comprising a distinct subclassification, as described in this chapter, shall be completely separated from other subclassifications by fire-resistive assemblies in accordance with NFPA *101* or *NFPA 5000*, as specified in 6.2.6 and Table 6.2.6.1, unless separation is provided by approved existing separations.

6.2.6.1.1 Subclassification separations shall be classified as 2-hour fire resistance rated or 1-hour fire resistance rated, and shall meet the requirements of *NFPA 5000*, Chapter 8, or NFPA *101*, Chapter 8.

6.2.6.1.2 The fire resistance rating specified in Table 6.2.6.1 shall be permitted to be reduced by 1 hour, but in no case shall it be reduced to less than 1 hour, where the facility is protected throughout by an approved automatic sprinkler system in accordance with Section 9.2.

6.2.6.2 Subclassification separations shall be vertical, horizontal, or both, or, when necessary, of such other form as required to provide complete separation between subclassification divisions in the structure.

6.2.6.3 Where the subclassification separation is horizontal, structural members supporting the separation shall be protected by an equivalent fire-resistive construction.

6.2.7 If there is a change in subclassification, the facility shall meet the requirements for the new subclassification.

6.3 Categorization of Animals.

6.3.1 Animal Type. The type of animal shall be categorized in each area of the animal housing facility in accordance with 6.3.1.1 and 6.3.1.2.

6.3.1.1 Category A. Category A animals shall include any of the following types of animals:

(1)* Animal(s) that pose a potential risk to the health or safety of rescuers or the general public

(2)* Animal(s) that cannot be removed without potential risk to the health and welfare of the animal or other animals

(3)* Animal(s) that are impossible or impractical to move

(4)* Animal(s) that are not mobile or not in a mobile enclosure

Table 6.2.6.1 Required Fire Resistance–Rated Separation for Subclassification in Hours

	Class 1 Facility	Class 2 Facility	Class 3 Facility
Class 1 Facility	—	1	2
Class 2 Facility	1	—	1
Class 3 Facility	2	1	—

Note: See 6.2.6.1.2 for fire-resistance rating reductions.

6.3.1.2 Category B. Category B animals shall include all agricultural animals and any animals not in Category A, as specified in 6.3.1.1.

6.3.2 Question of Categorization. Animal categories shall be subject to the ruling of the AHJ where there is a question of categorization.

6.3.3 Change in Animal Category. If the category of animal in an animal housing facility changes, the facility shall meet the requirements for the new animal category.

Chapter 7 Construction and Separation Requirements

7.1* Types of Construction. The types of construction for animal housing facilities shall be in accordance with NFPA 220 or *NFPA 5000*, Section 7.2.

7.2 Height and Area Requirements.

7.2.1 General. The height and area requirements for the occupancy of the animal housing facility shall be in accordance with *NFPA 5000*, Section 7.4.

7.2.1.1 Exterior areas such as corrals, paddocks, or other fenced holding areas attached to animal housing facilities shall not be included in the calculated allowable area per story.

7.2.1.2 If such exterior areas are partially or totally covered by extended roof structures integral with the building, the line of primary structure supporting such roofed areas shall be considered exterior wall lines when determining location on property.

7.2.2* Additional Requirements. In addition to the requirements of 7.2.1, the allowable number of stories above grade where the animal housing facilities are permitted and the allowable area per story of animal housing facilities shall not exceed the limits set forth in Table 7.2.2. The values in Table 7.2.2 for sprinklered facilities shall apply to facilities protected throughout with an approved, electrically supervised automatic sprinkler system in accordance with Section 9.2.

7.2.3 Maximum Facility Area. The maximum area of the animal housing facilities within a building or structure shall be determined by multiplying the allowable area per story, as determined by Table 7.2.2, by the facility's number of stories up to a maximum of three stories.

7.2.4 Multiple Subclassifications. Where an animal housing facility is occupied by animals of two or more subclassifications, the animal housing facility shall comply with this section.

7.2.4.1 Mixed Subclassifications. Animal housing facilities with mixed subclassifications complying with 6.2.5 shall have their required type of construction determined by applying the most restrictive type of construction to the entire animal housing facility.

7.2.4.2 Separated Subclassifications. Animal housing facilities with separated occupancies complying with 6.2.6 shall have their required type of construction determined in accordance with 7.2.4.2.1 and 7.2.4.2.2.

Table 7.2.2 Allowable Facility Height and Areas

Construction Type		I (442)		I (332)		II (222)		II (111)		II (000)		III (211)		III (200)		IV		V (111)		V (000)

For SI units, 1 ft = 0.3048 m, 1 ft^2 = 0.093 m^2.
S: Sprinklered. Allowable facility height in feet and allowable number of stories above grade in facilities protected with an automatic sprinkler system as specified in 7.2.2.
N: Nonsprinklered. Allowable facility height in feet and allowable number of stories above grade in facilities not protected with an automatic sprinkler system as specified in 7.2.2.
UL: Unlimited.
NP: Not permitted.
Note: Within each subclassification, “Stories” refers to the allowable number of stories above grade where the animal housing facilities are permitted to be located; “Area” refers to the allowable area per story.

7.2.4.2.1 The location of each separated subclassification in the animal housing facility shall comply with the story requirements of 7.2.2.

7.2.4.2.2 For each story in the animal housing facility, the sum of the ratios of the per story area of each separated subclassification divided by the allowable area per story as determined by Table 7.2.2 shall not exceed 1.0.

7.3 Stall, Cage, and Enclosure Requirements.

7.3.1 Stalls, cages, and enclosure requirements shall be based on established standards for the specific animal and facility type.

7.3.2* Animal enclosures shall not interfere with egress or extrication from the enclosure.

7.3.3 Modifications to 7.3.1 and 7.3.2 shall be permitted for temporary (i.e., less than 12 hours) holding areas with the approval of the AHJ.

7.4 Exposure Protection. Adjacent buildings shall be separated in accordance with *NFPA 5000*, Chapter 7.

7.5 Structural Design.

7.5.1 Structural design shall be subject to the requirements of *NFPA 5000*, Chapter 35, and this section.

7.5.2* Structural design criteria for walls and fence assemblies providing animal containment shall be designed to withstand the horizontal forces exerted by the animal occupants.

7.6 Fire-Rated Separations Between Animal Housing Facilities and Hazardous Areas.

7.6.1 Animal housing facilities shall be separated with a 2-hour fire resistance-rated enclosure from hazardous areas, including, but not limited to, feed rooms, tack rooms, vehicle or equipment storage rooms, blacksmith shops, kitchens, mechanical equipment rooms, and similar areas.

7.6.2 In buildings protected throughout with an approved, supervised automatic sprinkler system in accordance with NFPA 13, animal housing facilities shall be permitted to be separated with a 1-hour fire resistance-rated enclosure from the hazardous areas identified in 7.6.1.

7.7 Wildland/Urban Interface or Wildland/Urban Intermix. Animal housing facilities located in a wildland/urban interface or wildland/urban intermix shall comply with this standard and the construction requirements of NFPA 1144.

Chapter 8 Means of Egress Requirements

8.1 General. Means of egress for Category A and Category B animals shall be in accordance with this chapter.

8.1.1* Category A. Category A animals that can be safely egressed to a holding area, without human contact, shall have adequate means of egress provided.

8.1.2 Category B. Category B animals, which will egress with an animal handler, shall have means of egress that comply with NFPA *101* or *NFPA 5000*, and 8.1.2.1 through 8.1.2.4.

8.1.2.1 Number of Means of Egress.

8.1.2.1.1 Two means of egress for human and animal occupants, as a minimum, shall be provided in every facility, section, and area where size, occupancy, and arrangement endanger occupants attempting to use a single means of egress that is blocked by fire or smoke.

8.1.2.1.2 Where two means of egress are required, they shall be arranged to minimize the possibility that both might be rendered impassable by the same emergency condition.

8.1.2.2 Minimum Width of Doors. The minimum width of the door openings in means of egress shall be the greater of the following:

(1) Clear width of 32 in. (815 mm)
(2)* One-and-one-half times the largest average width of the following:
  (a) Largest animal using the door
  (b) Any associated equipment necessary for egress

8.1.2.3 Minimum Height of Doors. The minimum height of the door openings in means of egress shall accommodate the animal, human, and any associated equipment.

8.1.2.4* Exit Travel Distances.

8.1.2.4.1 In animal housing facilities not sprinklered in accordance with Section 9.2, or in animal housing facilities containing agricultural livestock, exit travel distance shall not exceed 75 ft (23 m) from any point in the facility.

8.1.2.4.2 In animal housing facilities sprinklered in accordance with Section 9.2, exit travel distance shall not exceed 100 ft (30 m) from any point in the facility.

8.2* Animal Occupant Load. Animal occupant load shall be determined based upon approved industry standards specific to the size of the animal and the stall, cage, and enclosure configurations.

Chapter 9 Requirements for Protection from Fire and Special Hazards

9.1 General.

9.1.1 Requirements for protection from fire and special hazards shall be in accordance with NFPA 1, NFPA *101*, or *NFPA 5000*, and this chapter.

9.1.2 Where a change in subclassification occurs and the installed fire protection systems are no longer necessary or no longer required, the facility owner shall either maintain the systems in full operation or completely remove them.

9.2 Sprinkler Protection.

9.2.1 Where automatic sprinklers are required by this standard throughout the animal housing facility, the system shall be installed in accordance with the requirements of Section 9.2 and the requirements of NFPA 13.

9.2.2 Occupancy and commodity classifications shall be in accordance with NFPA 13.

9.2.3 Quick-response sprinklers shall be utilized in animal housing facilities.

9.2.4 Automatic sprinkler systems shall be arranged to transmit the alarm automatically via any of the following means acceptable to the authority having jurisdiction and shall be in accordance with *NFPA 72*:

(1) Auxiliary fire alarm system
(2) Central station fire alarm system
(3) Proprietary supervision station fire alarm system
(4) Remote supervising station fire alarm system

9.2.4.1 Where a fire alarm system is not required by another section of this standard, automatic sprinkler system monitoring shall be in accordance with 23.8.5.5 of *NFPA 72*.

9.2.4.2 A single manual pull station shall be provided in accordance with 23.8.5.1 of *NFPA 72* at a location approved by the authority having jurisdiction.

9.3 Fire Alarm Systems.

9.3.1 Where fire alarm systems are required by this standard throughout the animal housing facility, alarm systems shall be in accordance with *NFPA 72* and the requirements of this section.

9.3.2 The alarm system shall sound an audible and visual exterior alarm for purposes of initiating emergency action.

9.3.2.1* Modifications to 9.3.2 shall be permitted to accommodate the needs of the animal occupants, with approval of the AHJ.

9.3.3 Where fire alarm graphic annunciator panels are provided, they shall identify animal areas within the building.

9.3.4 Where the locations of animal facilities are sensitive, the specific locations of animal housing will be provided to the fire department but will not be subject to the graphic annunciator panel requirement in 9.3.3.

9.4 Fire Extinguishers.

9.4.1 Where fire extinguishers are required by this standard throughout the animal housing facility, fire extinguishers shall be provided in accordance with NFPA 10.

9.4.2 Extinguishers in accordance with 9.4.1 shall have a minimum 2-A:10-B:C rating and shall be not more than a 50 ft (15.2 m) travel distance from any point within the animal housing facility.

9.4.3 Livestock areas not typically occupied by humans shall have a minimum 2-A:10:B:C extinguisher located at each exit.

9.4.4 Placement of the fire extinguishers shall be determined by the AHJ so as to prevent injury to or damage by the animal occupants.

9.5 Lightning Protection. Where lightning protection is required by the local building code, lightning protection shall be in accordance with NFPA 780.

9.6 Special Hazards.

9.6.1 Open Burning.

9.6.1.1* No open burning shall be permitted.

9.6.1.2 Open flame heating devices shall not be allowed other than as permitted by the following:

(1) NFPA 31, *Standard for the Installation of Oil-Burning Equipment*
(2) NFPA 54/ANSI Z223.1, *National Fuel Gas Code*
(3) NFPA 58, *Liquefied Petroleum Gas Code*
(4) *NFPA 70, National Electrical Code*
(5) NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*
(6) NFPA 90B, *Standard for the Installation of Warm Air Heating and Air-Conditioning Systems*
(7) NFPA 211, *Standard for Chimneys, Fireplaces, Vents, and Solid Fuel–Burning Appliances*

9.6.1.3 For animal housing facilities with fuel-burning appliances or equipment, carbon monoxide detection shall be installed in accordance with NFPA 720.

9.6.2 Smoking.

9.6.2.1 Smoking shall be prohibited in animal housing facilities.

9.6.2.2 Warning signs shall be posted.

9.6.3 Waste Removal and Housekeeping.

9.6.3.1 A procedure for general housekeeping, cleanliness, animal waste removal, and orderliness shall be maintained.

9.6.3.2 Detached noncombustible trash containers located no less than 20 ft (6 m) from any animal housing structure, for other than animal waste, shall be provided and a frequent removal program shall be established.

9.6.3.3 Aisles, hallways, or other types of corridors of animal housing facilities shall not be used in any form for permanent storage.

9.6.4 Electrical Systems and Appliances.

9.6.4.1* Electrical systems and appliances shall be installed in accordance with the requirements of *NFPA 70.*

9.6.4.2 Use of any portable electrical appliance shall be restricted as follows:

(1) Multiple-outlet adapters shall be prohibited.
(2) Not more than one continuous extension cord shall be used to connect one appliance to the fixed receptacle, and such cord shall be listed for hard service and properly sized for the intended application.
(3) Extension cords shall be used only on a temporary (immediate) basis.

9.6.4.3 Extension cords shall not be supported by any metal objects such as nails, screws, hooks, or pipes.

9.6.4.4 Plug caps and receptacles used in extension cords shall be heavy-duty type equipped with a reliable grounding pole and shall be attached to the cord in a manner to provide strain relief.

9.6.4.5 All electrical appliances used in the animal housing facility shall be listed for commercial use.

9.6.4.6 Outdoor electrical appliances served by the animal housing facility's electrical system shall be installed in accordance with *NFPA 70.*

9.6.4.7 Portable cooking and heating appliances shall be used only in spaces designated for such use and separated from the animal housing facility.

9.6.4.8 Portable electrical heating and cooking appliances shall be of a type that automatically interrupts electrical current to the heating element when the appliance is not in its normal operating position (tip-over disconnect).

9.6.4.9 Use of exposed-element heating appliances, such as immersion heaters and space heaters, shall be prohibited.

9.6.4.10 Receptacles and wiring shall be installed in positions that minimize the possibility of damage by or injury to the animal occupants.

9.6.4.11 Permanently installed lighting shall be provided throughout the animal housing facility.

9.6.5 Flammable Liquids. The storage of flammable and combustible liquids, except those used for medicinal purposes, shall be prohibited.

9.6.6 Control of Vehicular Traffic.

9.6.6.1 All vehicular access shall be subject to local established rules.

9.6.6.2 Aisles, hallways, and other types of corridors shall be maintained clear of obstruction at all times, and access to fire equipment shall not be blocked.

9.7 Vertical Openings. Where required by the AHJ, every vertical opening between the floors of an animal housing facility shall be enclosed or protected, as necessary, to provide the following:

(1) Reasonable safety to animal and human occupants while using the means of egress by preventing spread of fire, smoke, or fumes through vertical openings from floor to floor to allow occupants to complete their use of the means of egress
(2) Limitation of damage to the facility and its contents

9.8 Special Requirements for Category A Animals.

9.8.1 Sprinkler Systems. Animal housing facilities with Category A animals or horses shall be sprinklered throughout in accordance with Section 9.2.

9.8.2 Smoke Control Systems. Animal housing facilities with Category A animals or horses shall have a smoke control system unless modified as approved by the AHJ.

9.8.2.1* Smoke control systems shall be installed, inspected, tested, and maintained in accordance with NFPA 92 or nationally recognized standards, engineering guides, or recommended practices.

9.8.2.2 The engineer of record shall identify clearly the intent of the system, the design method used, the appropriateness of the method used, and the required means of inspecting, testing, and maintaining the system.

9.8.2.3 Acceptance testing shall be performed by a special inspector in accordance with the following:

(1) Special inspections and tests shall be performed to verify the operation of the smoke control system in its final condition for acceptance by the AHJ.
(2) The design documents shall provide the procedures and methods to be used and items subject to special inspections and tests.
(3) The special inspector shall submit an inspection and test report to the AHJ and registered design professional.

9.8.2.4 Smoke Control System Operation.

9.8.2.4.1 Smoke control systems shall be activated automatically by sprinkler waterflow, smoke detection, or other approved detection systems in accordance with *NFPA 72.* Smoke control systems shall remain operational throughout the emergency.

9.8.2.4.2 Means for manual operation of smoke control systems shall be provided at an approved location.

9.8.3* Areas Requiring Human Attendance. With the approval of the AHJ, surgical, procedure, and treatment areas where animals are anesthetized or otherwise require human attendance shall be designed, constructed, and maintained with a defend-in-place strategy to allow continued human attendance to minimize the unnecessary loss of animal life.

9.8.4* Additional Safeguards. For animal housing facilities with Category A animals, the AHJ shall be permitted to require additional safeguards necessary to protect animal occupants that cannot be evacuated safely.

Chapter 10 Interior Finishes, Contents, and Furnishings

10.1 General.

10.1.1 Interior finishes, contents, and furnishings shall be in accordance with Section 10.2 of NFPA *101*, or Sections 10.2 and 10.3 of *NFPA 5000*, and this chapter.

10.1.1.1 Interior wall and ceiling finish materials shall be Class A or Class B in accordance with ASTM E84, *Standard Test Method of Surface Burning Characteristics of Building Materials*, or ANSI/UL 723, *Standard for Test of Surface Burning Characteristics of Building Materials*, in exits and in exit access corridors.

10.1.1.2 Interior wall and ceiling finish materials shall be Class A, Class B, or Class C in accordance with ASTM E84 or ANSI/UL 723 in all other areas.

10.1.1.3 Interior wall and ceiling finish materials tested in accordance with NFPA 286 and complying with the requirements shown in Section 10.2 of NFPA *101*, or Sections 10.2 and 10.3 of *NFPA 5000,* shall be permitted to be used in all areas where a Class A, Class B, or Class C finish material is used in accordance with ASTM E84 or ANSI/UL 723.

10.1.2 The toxicity of finishes, contents, furnishings, and their treatments for the animals housed in the facility shall be minimized.

10.2 Insulation. Exposed insulation shall not be permitted in animal housing facilities.

Chapter 11 Class 1 Animal Housing Facilities

11.1 General.

11.1.1* Application. Class 1 animal housing facilities shall be in accordance with NFPA *101*, Chapter 42; or *NFPA 5000*, Chapter 30, as a minimum, and this chapter.

11.1.2 Minimum Construction Requirements. Class 1 animal housing facilities shall be constructed in accordance with Chapter 7.

11.1.3 Occupant Load.

11.1.3.1* Human Occupants. In Class 1 animal housing facilities, the occupant load, in number of persons for whom means of egress and other provisions are required, shall be determined in accordance with NFPA *101*, Chapter 42; or *NFPA 5000*, Chapter 30, as a minimum.

11.1.3.2 Animal Occupants. In Class 1 animal housing facilities, the occupant load, in number of animals for whom means of egress and other provisions are required, shall be determined in accordance with Chapter 8.

11.2 Means of Egress Requirements.

11.2.1 General. Each required means of egress shall be in accordance with the applicable portions of Chapter 8.

11.2.2 Means of Egress Components.

11.2.2.1 General. Components of means of egress shall be limited to the types described in NFPA *101*, Chapter 7; or *NFPA 5000*, Chapter 11; Chapter 8 of this standard; and as modified in this subsection.

11.2.2.2 Ramps.

11.2.2.2.1 Ramps complying with NFPA *101* and *NFPA 5000* shall be permitted for human occupants.

11.2.2.2.2* Ramps for animal egress shall be designed to safely accommodate the animal occupants.

11.2.3 Number of Means of Egress. See Chapter 8.

11.2.4 Special Means of Egress Features. (Reserved)

11.3 Protection.

11.3.1 Detection, Alarm, and Communications Systems.

11.3.1.1 General. A fire alarm system in accordance with Section 9.3 shall be required in accordance with this subsection.

11.3.1.1.1 In animal housing facilities greater than 3000 ft^2 (280 m^2) but no more than 20,000 ft^2 (1860 m^2), a local fire alarm system shall be provided.

11.3.1.1.2 In animal housing facilities greater than 20,000 ft^2 (1860 m^2), a monitored fire alarm system shall be provided.

11.3.1.2 Existing Systems. Approved existing installations shall be permitted to be continued in use.

11.3.2 Carbon Monoxide Detection Systems. For animal housing facilities with fuel-burning appliances or equipment, carbon monoxide detection shall be installed in accordance with 9.6.1.3.

11.3.3 Fire Extinguishers. Fire extinguishers shall be provided in accordance with Section 9.4.

11.3.4 Lightning Protection. Lightning protection shall be required in accordance with Section 9.5.

11.3.5 Special Hazards. Special hazards shall be addressed in accordance with Section 9.6.

11.3.6 Vertical Openings. Where required by the AHJ, vertical openings shall be in accordance with Section 9.7.

11.3.7 Special Requirements for Category A Animals. Class 1 animal housing facilities with Category A animals or horses shall be in accordance with Section 9.8.

11.3.8 Interior Finishes, Contents, and Furnishings. Interior finishes, contents, and furnishings shall be in accordance with Chapter 10.

11.4 Operating Features.

11.4.1 Disaster/Emergency Management Programs. A disaster/emergency management program shall be required in accordance with 4.3.4.

11.4.2 Disaster/Emergency Drills. In all Class 1 animal housing facilities, animal handlers, employees, and supervisory personnel shall hold disaster/emergency drills once annually in accordance with 4.3.5.

11.4.3 Extinguisher Training. All employees of Class 1 animal housing facilities shall be annually instructed in the use of portable fire extinguishers.

Chapter 12 Class 2 Animal Housing Facilities

12.1 General.

12.1.1* Application. Class 2 animal housing facilities shall be in accordance with NFPA *101*, Chapter 38, or *NFPA 5000*, Chapter 28, as a minimum, and this chapter.

12.1.2 Minimum Construction Requirements. Class 2 animal housing facilities shall be constructed in accordance with Chapter 7.

12.1.3 Occupant Load.

12.1.3.1 Human Occupants. The occupant load, in number of persons for whom means of egress and other provisions are required, shall be determined in accordance with NFPA *101*, Chapter 38, or *NFPA 5000*, Chapter 28, as a minimum.

12.1.3.2 Animal Occupants. In Class 2 animal housing facilities, the occupant load, in number of animals for whom means of egress and other provisions are required, shall be determined in accordance with Chapter 8.

12.2 Means of Egress Requirements.

12.2.1 General. Each required means of egress shall be in accordance with the applicable portions of Chapter 8.

12.2.2 Means of Egress Components.

12.2.2.1 General. Components of means of egress shall be limited to the types described in NFPA *101*, Chapter 7; or *NFPA 5000*, Chapter 11; Chapter 8 of this standard; and as modified in this subsection.

12.2.2.2 Ramps.

12.2.2.2.1 Ramps complying with NFPA *101* and *NFPA 5000* shall be permitted for human occupants.

12.2.2.2.2* Ramps for animal egress shall be designed to safely accommodate the animal occupants.

12.2.3 Number of Means of Egress. See Chapter 8.

12.2.4 Special Means of Egress Features. (Reserved)

12.3 Protection.

12.3.1 Detection, Alarm, and Communications Systems.

12.3.1.1 General. A fire alarm system in accordance with Section 9.3 shall be required in accordance with this subsection.

12.3.1.1.1 In animal housing facilities greater than 3000 ft^2 (280 m^2) but no more than 10,000 ft^2 (930 m^2), a local fire alarm system shall be provided.

12.3.1.1.2 In animal housing facilities greater than 10,000 ft^2 (930 m^2), a monitored fire alarm system shall be provided.

12.3.1.2 Existing Systems. Approved existing installations shall be permitted to be continued in use.

12.3.2 Carbon Monoxide Detection Systems. For animal housing facilities with fuel-burning appliances or equipment, carbon monoxide detection shall be installed in accordance with 9.6.1.3.

12.3.3 Fire Extinguishers. Fire extinguishers shall be provided in accordance with Section 9.4.

12.3.4 Lightning Protection. Lightning protection shall be required in accordance with Section 9.5.

12.3.5 Special Hazards. Special hazards shall be addressed in accordance with Section 9.6.

12.3.6 Vertical Openings. Where required by the AHJ, vertical openings shall be in accordance with Section 9.7.

12.3.7 Special Requirements for Category A Animals. Class 2 animal housing facilities with Category A animals or horses shall be in accordance with Section 9.8.

12.3.8 Interior Finishes, Contents, and Furnishings. Interior finishes, contents, and furnishings shall be in accordance with Chapter 10.

12.4 Operating Features.

12.4.1 Disaster/Emergency Management Programs. A disaster/emergency management program shall be required in accordance with 4.3.4.

12.4.2 Disaster/Emergency Drills. In all Class 2 animal housing facilities, animal handlers, employees, and supervisory personnel shall hold disaster/emergency drills annually in accordance with 4.3.5.

12.4.3 Extinguisher Training. All employees of Class 2 animal housing facilities shall be annually instructed in the use of portable fire extinguishers.

Chapter 13 Class 3 Animal Housing Facilities

13.1 General.

13.1.1* Application. Class 3 animal housing facilities shall be in accordance with NFPA *101*, Chapter 36, or *NFPA 5000*, Chapter 27, as a minimum, and this chapter.

13.1.2 Minimum Construction Requirements. Class 3 animal housing facilities shall be constructed in accordance with Chapter 7.

13.1.3 Occupant Load.

13.1.3.1 Human Occupants. The occupant load, in number of persons for whom means of egress and other provisions are required, shall be determined in accordance with NFPA *101*, Chapter 36, or *NFPA 5000*, Chapter 27, as a minimum.

13.1.3.2 Animal Occupants. In Class 3 animal housing facilities, the occupant load, in number of animals for whom means of egress and other provisions are required, shall be determined in accordance with Chapter 8.

13.2 Means of Egress Requirements.

13.2.1 General. Each required means of egress shall be in accordance with the applicable portions of Chapter 8.

13.2.2 Means of Egress Components.

13.2.2.1 General. Components of means of egress shall be limited to the types described in NFPA *101*, Chapter 7; or *NFPA 5000*, Chapter 11; Chapter 8 of this standard; and as modified in this subsection.

13.2.2.2 Ramps.

13.2.2.2.1 Ramps complying with NFPA *101* and *NFPA 5000* shall be permitted for human occupants.

13.2.2.2.2* Ramps for animal egress shall be designed to safely accommodate the animal occupants.

13.2.3 Number of Means of Egress. See Chapter 8.

13.2.4 Special Means of Egress Features. (Reserved)

13.3 Protection.

13.3.1 Detection, Alarm, and Communications Systems.

13.3.1.1 General. A monitored fire alarm system in accordance with Section 9.3 shall be required in all Class 3 animal housing facilities.

13.3.1.2 Existing Systems. Approved existing installations shall be permitted to be continued in use.

13.3.2 Carbon Monoxide Detection Systems. For animal housing facilities with fuel-burning appliances or equipment, carbon monoxide detection shall be installed in accordance with 9.6.1.3.

13.3.3 Fire Extinguishers. Fire extinguishers shall be provided in accordance with Section 9.4.

13.3.4 Lightning Protection. Lightning protection shall be required in accordance with Section 9.5.

13.3.5 Special Hazards. Special hazards shall be addressed in accordance with Section 9.6.

13.3.6 Vertical Openings. Where required by the AHJ, vertical openings shall be in accordance with Section 9.7.

13.3.7 Special Requirements for Category A Animals. Class 3 animal housing facilities with Category A animals or horses shall be in accordance with Section 9.8.

13.3.8 Interior Finishes, Contents, and Furnishings. Interior finishes, contents, and furnishings shall be in accordance with Chapter 10.

13.4 Operating Features.

13.4.1 Disaster/Emergency Management Programs. A disaster/emergency management program shall be required in accordance with 4.3.4.

13.4.2 Disaster/Emergency Drills. In all Class 3 animal housing facilities, animal handlers, employees, and supervisory personnel shall hold disaster/emergency drills semiannually in accordance with 4.3.5.

13.4.3 Extinguisher Training. All employees of Class 3 animal housing facilities shall be annually instructed in the use of portable fire extinguishers.

Annex A Explanatory Material

Annex A is not a part of the requirements of this NFPA document but is included for informational purposes only. This annex contains explanatory material, numbered to correspond with the applicable text paragraphs.

A.1.1.1 The requirements of NFPA 150 recognize the following fundamental principles:

(1) Animals are sentient beings with a value greater than that of simple property.
(2) Animals, both domesticated and feral, lack the ability of self-preservation when housed in buildings and other structures.
(3) Current building, fire, and life safety codes do not address the life safety of the animal occupants.

The requirements found in NFPA 150 are written with the intention that animal housing facilities will continue to be designed, constructed, and maintained in accordance with the applicable building, fire, and life safety codes. The requirements herein are not intended to replace or rewrite the basic requirements for the human occupants. Instead, NFPA 150 provides additional minimum requirements for the protection of the animal occupants and the human occupants who interact with those animals in these facilities.

NFPA 150 is divided into three major sections: The first section, Chapters 1 through 3, contains only administrative requirements, while the second section, Chapters 4 through 10, provides general requirements for all facilities housing animals (i.e., facility subclassification, animal category, construction, means of egress, fire protection, and interior finish requirements), and the third section, Chapters 11–13, includes specific requirements focused on the class of the facility.

A.1.3.1 While it would be appropriate for NFPA 150 to clearly establish a minimum number of animals above which the requirements of NFPA 150 apply, the necessary technical information to make these decisions is simply not available at this time. Instead, in 1.3.1, it is stated that, if a facility requires a permit or license from the local, state, or federal authorities to function, it must comply with this standard. With this approach, it is understood that an adopting jurisdiction could further modify the application of the standard to fit its local situation.

A.1.3.3 An extensive modification includes modification of an entire building or an entire occupancy within a building and should be considered a reconstruction. Modification work that is exclusively electrical, mechanical, or structural or that exclusively involves plumbing or equipment used in the care or treatment of animals or the fire protection system should not be considered a reconstruction, regardless of its extent. Where the total area of all the rehabilitation work areas included in a modification exceeds 50 percent of the area of the building, the work should be considered a reconstruction.

A.1.3.4 In this particular situation, the definition of *temporary* is left to the applicable building, life safety, and fire codes enforced in the jurisdiction.

A.3.2.1 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

A.3.2.2 Authority Having Jurisdiction (AHJ). The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A.3.2.4 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A.3.3.2.1 Confined Animals. This includes animals in pens near or adjacent to a structure where they would be endangered by smoke, heat, fire spread, or structural failure.

A.3.3.3 Animal Handler. This includes but is not limited to attendants, exhibitors, hands, keepers, groomers, technicians, trainers, veterinarians, wranglers, or their assistants.

A.3.3.4 Animal Housing Facility. This includes but is not limited to barns, kennels, coops, stables, sheds, pens, corrals, runs, vivaria, terraria, laboratories, and zoos. Adjacent exterior spaces include areas near or adjacent to a structure where confined animals would be endangered by smoke, heat, fire spread, or structural failure.

A.3.3.17 Protection. For the purposes of this standard, *protection* takes various distinct forms. The specific provision of the standard will address what the standard intends as an acceptable device, material, or system. With regard to structural fire protection, *protection* or *protected* usually means an assembly of materials that have achieved a specified level of fire resistance as demonstrated by NFPA 251 (withdrawn). For fire suppression systems, *protected* usually means being provided with an approved automatic sprinkler system or similar automatic fire suppression system. The type of *protection* desired must be clearly understood within the context of the item under consideration.

A.4.1 The overall goals of this standard are presented in 4.1.1. These overall goals are treated in greater depth in 4.1.3 and 4.1.4. In each of these subsections, an overall goal for the subsection is defined, specific goals relating to the overall goal are presented, and the objectives that relate to the specific goal follow. This format is intended to enhance the usability of the standard.

A.4.1.1 These highest level goals are intentionally general in nature. Each includes a broad spectrum of topics as shown in 4.1.3 and 4.1.4. Property protection is not included as a highest level goal, as it is contained in most of the other goals.

Safety is intended to indicate a need for protection against immediate or short-duration hazards, such as a fire or similar emergency.

A.4.1.2 The objectives are stated in more specific terms than the goals and tend to be more quantitative.

A.4.1.3.1.1 The phrase "reasonably safe from fire" is defined by subsequent language in this standard, primarily in the objectives.

A.4.1.3.1.2.2 In many cases, the other provisions of the standard that provide safety for occupants will satisfy this goal for protection of emergency responders.

A.4.1.3.2.1 The phrase "reasonably safe during normal use" is defined by subsequent language in this standard, primarily in the objectives. Certain requirements are provided to ensure that the occupants are safe during nonemergency use of the buildings. Failure to address these features could result in injuries to occupants in their normal day-to-day activities in the building.

A.4.1.3.2.2.3 Appropriate consideration should be given to the type of audible device selected, since some animals might respond in a detrimental way given a certain signal (e.g., a bell would be inappropriate as a fire alarm in a racetrack stable).

A.4.1.4.1.1 The long-term function of a building, in total, is not within the scope of this goal. This goal relates, however, to the long-term, continued operation and effectiveness of the building to satisfy the goals of safety and usability.

A.4.1.4.1.2 This objective is intended to apply to systems, features, and construction that are provided in the building for the purpose of meeting the other objectives and is not intended to apply to nonrequired systems, features, and construction.

A.4.2.4 Fire alarms alert occupants to initiate emergency procedures, facilitate orderly conduct of fire drills, and initiate response by emergency services.

A.4.3.1.3 This standard is not intended to address every conceivable arrangement of construction or use of animal housing facilities. These structures are unique in that the life safety of two important, but dramatically different, forms of life are addressed — humans and animals. These structures often involve the interaction of animals and people that are unfamiliar with one another's reaction to fire or other emergency conditions. For instance, for mobility impaired or other disabled individuals, the ability of the humans to egress can be impaired, hindered, or jeopardized by the movement of the animals. These facilities can also be located within or close to a process or other occupancy that elevates the risk to animals, but perhaps not to humans, beyond that contemplated by the standard. These facilities can be housed in a historic building.

If these or other special circumstances clearly exist, the AHJ can require alternative or additional fire protection features. These can include, but are not limited to, a performance-based analysis of the special condition, building fire evacuation plans, management policies on staff response to emergencies, a higher staff-to-client ratio, increased fire resistance ratings, or modification of fire suppression or fire alarm requirements.

A.4.3.4.2.1 Disaster/emergency management programs should include the following items based on the type of occupancy and hazards involved:

(1) Procedures for reporting of emergencies requiring relocation and/or evacuation of occupants
(2) Occupants or staff member duties during emergencies
(3) Floor plans identifying the locations of portable fire extinguishers, other manual fire-extinguishing equipment, other automatic or manual fire suppression systems, first aid equipment, hazardous material spill equipment, and equipment designated as necessary for the evacuation of animals
(4) Manual fire alarm pull stations and fire alarm control panels
(5) Floor plans identifying the primary and secondary routes of evacuation for each room or portion of the occupancy
(6) Floor plans indicating the locations of interior areas of refuge and animal occupied areas
(7) Site maps identifying the designated exterior assembly area for each evacuation route
(8) Assessments of both building systems and management features
(9) Use of alarms
(10) Transmission of alarm to fire department
(11) Response to alarms
(12) Procedures for isolation and/or extinguishment of fire
(13) Properties and location of hazardous storage or operations
(14) Special procedures for staff members who perform or shut down critical plant operations and/or attend to Category A animals
(15) A system to account for animal and human occupants and staff members after evacuation
(16) Designation of an emergency response coordinator and a back-up coordinator
(17) An alternate means of communications other than the fire alarm
(18) Emergency contact information
(19) Special procedures for animal handlers to address such items as animal bites and animal escapes

A.4.3.5 The purpose of disaster/emergency drills is to educate the participants in the fire safety features of the building, the egress facilities available, safe handling of the animal occupants, and the procedures to be followed. Speed in emptying buildings or relocating occupants, while desirable, is not the only objective. Prior to an evaluation of the performance of a disaster/emergency drill, an opportunity for instruction and practice should be provided. This educational opportunity should be presented in a nonthreatening manner, with consideration to the prior knowledge, age, and ability of the audience.

A.4.3.5.2.2 If a disaster/emergency drill is considered merely as a routine exercise from which some persons are allowed to be excused, there is a grave danger that, in an actual emergency, the evacuation and relocation will not be successful. However, there could be circumstances under which all occupants do not participate in a disaster/emergency drill.

A.5.1 The performance-based option of this standard establishes acceptable levels of risk for buildings and structures as addressed in Section 1.2. While the performance-based option of this standard does contain goals, objectives, and performance criteria necessary to provide for an acceptable level of risk, it does not describe how these goals, objectives, and performance criteria are to be met. Design and engineering are needed to meet the provisions of Chapter 5.

A.5.1.3 A third-party reviewer is a person or group of persons chosen by the authority having jurisdiction to review proposed performance-based designs. Qualifications of the third-party reviewer should include experience, education, and credentials that demonstrate knowledgeable and responsible use of applicable models and methods.

A.5.1.5 For guidance on reviewing performance-based designs, see the SFPE *Enforcer's Guide to Performance-Based Design Review*. Additional guidance on reviewing designs in which fire risk analysis is used can be found in NFPA 551.

A.5.1.6 Continued compliance with the goals and objectives of the standard involves many factors. The building construction — including openings, interior finish, and fire- and smoke-resistive construction — and the building and fire protection systems need to retain at least the same level of performance as is provided for the original design parameters. The use and occupancy should not change to the degree that assumptions made about the occupant characteristics, combustibility of furnishings, and existence of trained personnel are no longer valid. In addition, actions provided by other personnel, such as emergency responders, should not be diminished below the documented assumed levels. Also, actions necessary to maintain reliability of systems at the anticipated level need to meet the initial design criteria.

A.5.2.2.2 In many cases, the other provisions of the standard that provide safety for occupants will satisfy this goal for protection of emergency responders.

A.5.2.3.1 The phrase “reasonably safe during normal use” is defined by subsequent language in this standard, primarily in the objectives. Certain requirements are provided to ensure that the occupants are safe during nonemergency use of the buildings. Failure to address these features could result in injuries to occupants in their normal day-to-day activities in the building.

A.5.2.3.2.3 Appropriate consideration should be given to the type of audible device selected, since some animals might respond in a detrimental way given a certain signal (e.g., a bell would be inappropriate as a fire alarm in a racetrack stable).

A.5.4 In the context of this standard, design characteristics are those attributes of the building and its location, systems, contents, and occupants that need to be specified or quantified, or both, to allow evaluation of a design with respect to the goals, objectives, and performance criteria, using appropriate design scenarios and verification methods. Some design characteristics are specified in this standard. Others might be specified by the authority having jurisdiction to accommodate local conditions, and still others might be specified by the designer of the building.

A.5.4.1.5 This requirement includes assumptions about the interrelations between the performance of building elements and systems, occupant behavior, or emergency response actions that conflict with each other. For each design scenario, care needs to be taken to ensure that conflicts in actions do not occur. Typical conflicts could include the following:

(1) Assuming a fire door will remain closed during the fire to contain smoke, while this same door is used by occupants during egress from the area
(2) Assuming fire apparatus will arrive immediately from a distant location to provide water to fire department connections.

For example, an assumption that compartmentation blocking the passage of fire and smoke will be maintained at the door to a stairwell cannot be paired with an assumption that evacuation through that door will extend over many minutes.

A.5.4.2.1 Building contents and furnishings are not normally included in design specifications; however, in some cases, they might have an impact on building or occupant behavior. Where contents and furnishings could affect building or occupant behavior, the designer must present the authority having jurisdiction with detailed information about such contents and furnishings and their locations in the building to enable an assessment of their impact in various design scenarios to be determined. A designer must also clearly express the overall layout of the building, especially those items that might not appear on building plans but that could affect the performance of the building or the occupants. Examples include the layout of office cubicles that could affect emergency egress and temporary storage areas that could exceed permissible loading for a portion of a floor assembly.

A.5.4.2.2 Systems addressed by this requirement include but are not limited to automatic fire suppression systems and fire alarm systems. Performance issues that need to be documented might include response time indexes, discharge densities, and waterflow distribution patterns. Calculations should not include an unlimited supply of extinguishing agent if only a limited supply will be provided in the actual structure or building.

A.5.4.3.1 Guidance on human characteristics for use in design can be found in the SFPE *Engineering Guide to Predicting Human Behavior in Fire*. Guidance on animal characteristics for use in design can be formulated based on discussions with facility staff, animal handlers, researchers, and other subject matter experts including but not limited to industry associations and regulatory agencies.

A.5.4.3.5 The guidelines cited in A.7.3 for the minimum areas for stalls, cages, and enclosure areas can be used to develop appropriate occupant loads for the animal occupants. For animals not covered in A.7.3, other recognized industry guidelines should be consulted. The number of people expected to be contained in a room or area should be based on the occupant load factor specified in other approved sources.

A.5.4.3.6 For example, in research facilities, staff characteristics such as number, location, quality, and frequency of training should be considered.

A.5.5 Many events can occur during the life of a building; some have a higher probability of occurrence than others. Some events, though not typical, could have a devastating effect on a building. A reasonable design should be able to achieve the goals, objectives, and performance criteria of this standard for any typical or common design scenario and for some of the nontypical, potentially devastating scenarios, up to a level commensurate with society's expectations as reflected in this standard.

The challenge in selecting design scenarios is finding a manageable number that are sufficiently diverse and representative so that, if the design is reasonably safe for those scenarios, it should then be reasonably safe for all scenarios, except for those specifically excluded as being unrealistically severe or sufficiently infrequent to be fair tests of the design.

A.5.8.1 The SFPE *Engineering Guide to Performance-Based Fire Protection Analysis and Design of Buildings* describes the documentation that should be provided for a performance-based design.

Proper documentation of a performance design is critical to the design acceptance and construction. Proper documentation will also ensure that all parties involved understand what is necessary for the implementation, maintenance, and continuity of the fire protection design. If attention to detail is maintained in the documentation, then there should be little dispute during approval, construction, start-up, and use. Poor documentation could result in rejection of an otherwise good design, poor implementation of the design, inadequate system maintenance and reliability, and an incomplete record for future changes or for testing the design forensically.

A.5.8.11 Documentation for modeling should conform to ASTM E1472, *Standard Guide for Documenting Computer Software for Fire Models*, although most, if not all, models were originally developed before this standard was promulgated.

A.6.1.1 The user should reference *NFPA 5000* or NFPA *101* to obtain the general occupancy classification of an animal housing facility whether it's storage, business, mercantile, assembly, or other occupancy. If there are multiple occupancies within the facility, they will be in accordance with the mixed or separated occupancy requirements in *NFPA 5000*, Chapter 6, or NFPA *101*, Chapter 6. NFPA 150 and its subclassification, defined in Section 6.2, are intended to apply only to those portions of the facility housing animals.

A.6.2.1.1 Class 1 facilities include but are not limited to rest, feed, work, exercise, viewing, and production areas at facilities where there is no general public access or physical interaction with the animal occupants. These types of facilities include but are not limited to livestock and poultry processing plants, dairy barns, private breeding facilities, treatment and holding areas in veterinary clinics or hospitals, educational facilities, quarantine areas, respite facilities, and private kennel areas. It is assumed that these facilities will have no access by the general public, as defined in Chapter 3.

A.6.2.1.2 Class 2 facilities include but are not limited to rest, feed, work, exercise, viewing, and production areas at facilities where there is restricted general public access and interaction with the animal occupants. Restricted general public access permits limited access for people on an infrequent basis who do not have an intimate knowledge of the layout of the building or structure or the general behavior of the animals.

A.6.2.1.3 Class 3 facilities include but are not limited to rest, feed, work, exercise, production, or viewing areas at facilities where there is general public access and interaction with the animal occupants. These types of facilities include but are not limited to zoo display areas, petting zoos, show grounds/barns, and pet stores. General public access includes regular access for people who do not have an intimate knowledge of the layout of the building or structure or the general behavior of the animals.

A.6.2.4.1 See Figure A.6.2.4.1(a) and Figure A.6.2.4.1(b) for illustrations of the multiple subclassifications.

A.6.2.4.2 An example of a minor accessory subclassification could be a small public viewing area at a dairy production facility. The barn might meet the subclassification for a Class 1 facility. If the other subclassification is less than 25 percent of the gross floor area of the animal housing facility, then the provisions of a multiple subclassification would not apply, and the facility could be classified as the predominant subclassification (in this example, Class 1).

A.6.3.1.1(1) This includes wild or feral animals, zoonotic disease carriers, or poisonous animals.

A.6.3.1.1(2) This includes animals that are under anesthesia, injured or ill, immune-deficient, or infectious disease carriers.

A.6.3.1.1(3) This includes animals that are wild or feral, too large or too numerous, or in situations where there is inadequate staff-to-animal ratio for evacuation purposes or inadequate safeguards to deal with evacuated animals.

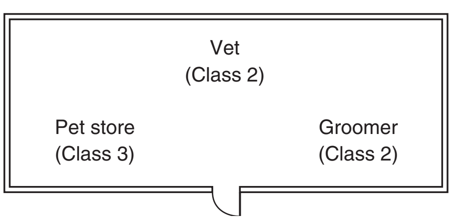

FIGURE A.6.2.4.1(a) Multiple Mixed Subclass.

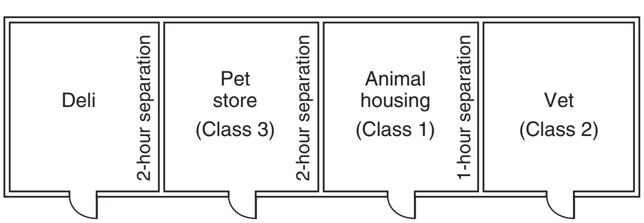

FIGURE A.6.2.4.1(b) Multiple Separated Subclass.

A.6.3.1.1(4) This includes animals that cannot be led by collars, halters, or other devices and equipment and animals that are not in mobile or rolling cages.

A.7.1 Table A.7.1 is a reprint of Table 7.2.1.1 from *NFPA 5000*.

A.7.2.2 Descriptions of the construction types found in Table 7.2.2 can be found in NFPA 220 and *NFPA 5000*.

A.7.3.2 Animals shall be able to lie down with their limbs extended in a normal manner without obstruction from enclosure sides or having to extend their feet through feed doors or bars.

A.7.5.2 Table A.7.5.2 lists the recommended animal enclosure horizontal design forces for a sampling of animals.

A.8.1.1 A holding area can be a temporary or permanent, internal or external area that provides a safe environment for an animal during an emergency. It could include, but is not limited to, a movable enclosure, pen, yard, paddock, or corral.

A.8.1.2.2(2) The width of the animal should be the widest part of the animal, including horns, antlers, and other appendages.

A.8.1.2.4 Exit distances are more stringent than those specified in NFPA *101* because of the difficulty of evacuating panicked animals from the facility in an emergency situation.

A.8.2 The guidelines cited in A.7.3 for the minimum areas for stalls, cages, and enclosure areas can be used to develop appropriate occupant loads for the animal occupants.

A.9.3.2.1 Consideration should be given to animal reactions and undue stress caused by audible sounds or flashing strobes. For example, in zoos, an acknowledge station where the keeper can disengage the notification appliances only in the animal areas could be incorporated into the design where acceptable to the AHJ. After the notification appliances are deactivated, another means, such as a red beacon, could be used as an alternative notification method. Other means acceptable to the AHJ might be more suitable for other animal housing occupancies.

A.9.6.1.1 This restriction is intended primarily to prohibit open flame heaters in the barn and stable-type areas. It is not intended to limit properly installed and equipped devices such as gas water heaters and blacksmith forges as long as they are approved by the AHJ.

A.9.6.4.1 Animal housing facilities containing agricultural livestock should be in accordance with *NFPA 70*, Article 547, Agricultural Buildings.

A.9.8.2.1 Because most animals require shelter in place, a smoke control system of some type is required. Tenable conditions such as the maximum and minimum exposure temperatures, sensitivity to sudden changes in temperature, maximum carbon monoxide concentrations, and the acceptable smoke layer height above the finished floor during a fire condition are not available for many animals. Data for design of an effective smoke control system can be obtained from facility staff, animal handlers, researchers, and other subject matter experts, including industry associations and regulatory agencies.

A.9.8.3 It is anticipated that if staff is to remain with anesthetized animals or animals that cannot be left unattended, addi-

tional safeguards would be necessary to ensure the safety of both human and animal occupants.

A.9.8.4 Additional safeguards can include such items as two-way communication, secondary animal containment, smoke compartments, and emergency response training and equipment in accordance with 4.3.4 (i.e., tranquilizers and other animal control equipment, and first-aid items).

A.11.1.1 Class 1 facilities are those facilities that are most closely related to storage occupancies. That is to say, they are characterized by relatively low human occupant loads in relation to the large size of the floor areas. The requirements found in Chapter 11 compare most closely to those requirements found in Chapter 42 of NFPA *101.* By no means should a Class 1 animal housing facility be automatically classified as a storage occupancy. The occupancy of an animal housing facility should be determined in accordance with NFPA *101* or *NFPA 5000,* based on the intended use of that facility. NFPA 150 makes additional requirements to safeguard the animal life within that facility.

A.11.1.3.1 In NFPA *101*, Chapter 42, there is no occupant load factor specified for storage occupancies. Rather, the actual probable maximum number of persons present needs to be considered in determining the occupant load.

A.11.2.2.2.2 Ramp design should be able to accommodate not only the size, weight, and capability of the animal, but also any animal handlers and equipment necessary for the animal's movement. It should also anticipate the animal's possible behavior during emergency situations.

A.12.1.1 Class 2 facilities are those facilities that are most closely related to business occupancies. These facilities typically include vet offices, grooming facilities, research labs, and so forth. The requirements found in Chapter 12 compare most closely to those requirements found in Chapter 38 of NFPA *101*. By no means should a Class 2 animal housing facility be automatically classified as a business occupancy. The occupancy of an animal housing facility should be determined in accordance with NFPA *101* or *NFPA 5000*, based on the intended use of that facility. NFPA 150 makes additional requirements to safeguard the animal life within that facility.

A.12.2.2.2.2 Ramp design should be able to accommodate not only the size, weight, and capability of the animal, but also any animal handlers and equipment necessary for the animal's movement. It should also anticipate the animal's possible behavior during emergency situations.

A.13.1.1 Class 3 facilities are those facilities that are most closely related to mercantile occupancies. In such facilities, the public might be in close proximity to the animals, in occupant loads typically associated with a mercantile occupancy. The requirements found in Chapter 13 compare most closely to those requirements found in Chapter 36 of NFPA *101*. By no means should a Class 3 animal housing facility be automatically classified as a mercantile occupancy. For instance, arenas with fixed seating for exhibition purposes of animals should probably be treated as assembly occupancies, since the public in the stands has little or no interaction with the animals and probably has separated means of egress from the animals. The occupancy of an animal housing facility should be determined in accordance with NFPA *101* or *NFPA 5000*, based on the intended use of that facility. NFPA 150 makes additional requirements to safeguard the animal life within that facility.

A.13.2.2.2.2 Ramp design should be able to accommodate not only the size, weight, and capability of the animal, but also any animal handlers and equipment necessary for the animal's movement. It should also anticipate the animal's possible behavior during emergency situations.

Annex B Sample Ordinance Adopting NFPA 150

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

B.1 The following sample ordinance is provided to assist a jurisdiction in the adoption of this standard and is not part of this standard.

ORDINANCE NO. ___________

An ordinance of the [*jurisdiction*] adopting the [*year*] edition of NFPA [*document number*], [*complete document title*], and documents listed in Chapter 2 of that [*code, standard*]; prescribing regulations governing conditions hazardous to life and property from fire or explosion; providing for the issuance of permits and collection of fees; repealing Ordinance No. _______ of the [*jurisdiction*] and all other ordinances and parts of ordinances in conflict therewith; providing a penalty; providing a severability clause; and providing for publication; and providing an effective date.

BE IT ORDAINED BY THE [*governing body*] OF THE [*jurisdiction*]:

SECTION 1 That the [*complete document title*] and documents adopted by Chapter 2, three (3) copies of which are on file and are open to inspection by the public in the office of the [*jurisdiction's keeper of records*] of the [*jurisdiction*], are hereby adopted and incorporated into this ordinance as fully as if set out at length herein, and from the date on which this ordinance shall take effect, the provisions thereof shall be controlling within the limits of the [*jurisdiction*]. The same are hereby adopted as the [*code, standard*] of the [*jurisdiction*] for the purpose of prescribing regulations governing conditions hazardous to life and property from fire or explosion and providing for issuance of permits and collection of fees.

SECTION 2 Any person who shall violate any provision of this code or standard hereby adopted or fail to comply therewith; or who shall violate or fail to comply with any order made thereunder; or who shall build in violation of any detailed statement of specifications or plans submitted and approved thereunder; or fail to operate in accordance with any certificate or permit issued thereunder; and from which no appeal has been taken; or who shall fail to comply with such an order as affirmed or modified by a court of competent jurisdiction, within the time fixed herein, shall severally for each and every such violation and noncompliance, respectively, be guilty of a misdemeanor, punishable by a fine of not less than $ _____ nor more than $_____ or by imprisonment for not less than ______ days nor more than ______ days or by both such fine and imprisonment. The imposition of one penalty for any violation shall not excuse the violation or permit it to continue; and all such persons shall be required to correct or remedy such violations or defects within a reasonable time; and when not otherwise specified the application of the above penalty shall not be held to prevent the enforced removal of prohibited conditions. Each day that prohibited conditions are maintained shall constitute a separate offense.

SECTION 3 Additions, insertions, and changes — that the [*year*] edition of NFPA [*document number*], [*complete document title*] is amended and changed in the following respects:

List Amendments

SECTION 4 That ordinance No. _________ of [*jurisdiction*] entitled [*fill in the title of the ordinance or ordinances in effect at the present time*] and all other ordinances or parts of ordinances in conflict herewith are hereby repealed.

SECTION 5 That if any section, subsection, sentence, clause, or phrase of this ordinance is, for any reason, held to be invalid or unconstitutional, such decision shall not affect the validity or constitutionality of the remaining portions of this ordinance. The [*governing body*] hereby declares that it would have passed this ordinance, and each section, subsection, clause, or phrase hereof, irrespective of the fact that any one or more sections, subsections, sentences, clauses, and phrases be declared unconstitutional.

SECTION 6 That the [*jurisdiction's keeper of records*] is hereby ordered and directed to cause this ordinance to be published.

[NOTE: An additional provision may be required to direct the number of times the ordinance is to be published and to specify that it is to be in a newspaper in general circulation. Posting may also be required.]

SECTION 7 That this ordinance and the rules, regulations, provisions, requirements, orders, and matters established and adopted hereby shall take effect and be in full force and effect [*time period*] from and after the date of its final passage and adoption.

NFPA®160

Standard for the

Use of Flame Effects Before an Audience

2016 Edition

This edition of NFPA 160, *Standard for the Use of Flame Effects Before an Audience,* was prepared by the Technical Committee on Special Effects. It was issued by the Standards Council on May 26, 2015, with an effective date of June 15, 2015, and supersedes all previous editions.

This edition of NFPA 160 was approved as an American National Standard on June 15, 2015.

Origin and Development of NFPA 160

NFPA 160, *Standard for Flame Effects Before an Audience,* was developed by the Technical Committee on Special Effects, which was established in 1994, in response to a recognized need for a document to provide guidance to public safety officials, designers, and operators of flame effects. The purpose of this standard is to provide requirements for reasonable protection for viewing audiences and performers of flame effects. The first edition of the standard was 1998.

For the 2001 edition, the Committee completed a partial revision of the standard. Revisions included amendments to standardized definitions, harmonization with the pyrotechnics special effects document, and editorial changes according to the *Manual of Style for NFPA Technical Committee Documents.*

The 2006 edition included a complete revision of the standard by the Committee. Key changes found in the 2006 edition included revisions to Chapter 3, Definitions; clarification of the document applicability by modifying the document title; definitions for temporary and permanent installations to correlate with the effect classifications based upon those terms; a new requirement for inspection intervals; and a new Annex C on inspection guidelines.

The 2006 edition of the standard also incorporated editorial changes according to the *Manual of Style for NFPA Technical Committee Documents.*

The 2011 edition of the standard incorporated amendments to the application section to clarify that NFPA 140, *Standard on Motion Picture and Television Production Studio Soundstages, Approved Production Facilities, and Production Locations,* applies to flame effect use when no audience is present. The Committee added definitions for the terms *performer* and *support personnel* extracted from NFPA 1126, *Standard for the Use of Pyrotechnics Before a Proximate Audience,* for consistency between the special effects documents. Requirements for development and approval of the flame effects plan were included. The Committee revised the separation distance requirements to eliminate the thermal flux provision and retain the skin surface temperature requirements. The skin surface temperature is based on a test method that can be more easily performed in the field.

The 2016 edition of NFPA 160 defines a hybrid flame effect and adds requirements for their use. The new edition of NFPA 160 indicates which portions of hybrid flame effects are covered by NFPA 160 and which are covered by NFPA 1126, since both documents apply, and adds explanatory annex material to provide further guidance on the simultaneous application of NFPA 160 and NFPA 1126. The 2016 edition also clarifies that the use of ground-based effects utilizing explosives, liquid fuels, or other combustibles in air show environments is not covered by NFPA 160 and provides a reference for the use of such effects.

This list represents the membership at the time the Committee was balloted on the final text of this edition. Since that time, changes in the membership may have occurred. A key to classifications is found at the back of the document.

NOTE: Membership on a committee shall not in and of itself constitute an endorsement of the Association or any document developed by the committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on the controlled use of flame, pyrotechnics, or other means of special effects for entertainment, exhibition, demonstration, or simulation before a proximate audience; and the design, fabrication, installation, testing, control, operation, and maintenance of user equipment, fuel storage, and sources for special effects before a proximate audience. This Committee does not have responsibility for documents on hazards other than those involving a proximate audience and the life safety considerations of the audience.

NFPA 160

Standard for the

Use of Flame Effects Before an Audience

2016 Edition

IMPORTANT NOTE: This NFPA document is made available for use subject to important notices and legal disclaimers. These notices and disclaimers appear in all publications containing this document and may be found under the heading "Important Notices and Disclaimers Concerning NFPA Documents." They can also be obtained on request from NFPA or viewed at www.nfpa.org/disclaimers.

UPDATES, ALERTS, AND FUTURE EDITIONS: New editions of NFPA codes, standards, recommended practices, and guides (i.e., NFPA Standards) are released on scheduled revision cycles. This edition may be superseded by a later one, or it may be amended outside of its scheduled revision cycle through the issuance of Tentative Interim Amendments (TIAs). An official NFPA Standard at any point in time consists of the current edition of the document, together with any TIAs and Errata in effect. To verify that this document is the current edition or to determine if it has been amended by any TIAs or Errata, please consult the National Fire Codes® Subscription Service or visit the Document Information (DocInfo) pages on the NFPA website at www.nfpa.org/docinfo. In addition to TIAs and Errata, the DocInfo pages also include the option to sign up for Alerts for each document and to be involved in the development of the next edition.

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates that explanatory material on the paragraph can be found in Annex A.

A reference in brackets [ ] following a section or paragraph indicates material that has been extracted from another NFPA document. As an aid to the user, the complete title and edition of the source documents for extracts in mandatory sections of the document are given in Chapter 2 and those for extracts in informational sections are given in Annex D. Extracted text may be edited for consistency and style and may include the revision of internal paragraph references and other references as appropriate. Requests for interpretations or revisions of extracted text shall be sent to the technical committee responsible for the source document.

Information on referenced publications can be found in Chapter 2 and Annex D.

Chapter 1 Administration

1.1* Scope. This standard shall provide requirements for the protection of the audience, support personnel, performers, the operator, assistants, and property where flame effects are used.

1.2 Purpose. The purpose of this standard shall be to provide minimum requirements for the design, manufacture, and operation of flame effects.

1.3 Application.

1.3.1* This standard shall apply to flame effects for entertainment, exhibition, demonstration, or simulation before an audience, including their design, fabrication, installation, testing, control, operation, and maintenance.

1.3.2 This standard shall apply to the following:

(1) Use of flame effects before an audience *(see 3.3.12, Flame Effect)*
(2) Design, fabrication, installation, testing, control, operation, and maintenance of equipment, materials, procedures, and systems used to produce flame effects
(3) Rehearsal, videotaping, audiotaping, or filming of any television, radio, or movie production if such production is before an audience and includes the use of flame effects
(4) Rehearsal of any production incorporating flame effects intended to be presented before an audience
(5) Storage and holding at a venue where flammable and combustible materials are to be used to create flame effects
(6) That portion or component of any hybrid flame effect that utilizes fuels, materials, devices, and methodologies governed by this standard.

1.3.3 This standard shall not apply to the following:

(1)* Flame effects produced solely by pyrotechnic special effects devices or pyrotechnic material
(2)* Use of pyrotechnic special effects
(3)* Storage of flammable solids, liquids, and gases not to be used to create flame effects
(4) Nitrocellulose-based flame projectors
(5) Manufacture, off-site storage, and transportation of materials and equipment used to produce flame effects
(6) Use of flame effects in fire training, except where there is an audience that is not part of the training
(7)* Manufacture, transportation, storage, sale, or use of model or high-power rocket motors
(8) Traditional nontheatrical public display of flames such as the following:
    (a) Use of lighted candles in restaurants or religious services
    (b) Fireplaces in areas open to the public
    (c) Restaurant cooking visible to the patrons
    (d) Listed Group II flame effects
    (e) Flame effects used in a fireworks display *(see NFPA 1123)*
(9) Use of consumer fireworks by the public
(10) Use of motor vehicles in races or sanctioned competitive sporting events
(11)* Use of ground-based effects utilizing explosives, liquid fuels, or other combustibles in air show environments

1.3.4* This standard shall not be used as a product standard.

1.3.5 When there is no audience present, NFPA 140. shall be used to regulate any flame effect use.

1.4 Retroactivity. The provisions of this standard reflect a consensus of what is necessary to provide an acceptable degree of protection from the hazards addressed in this standard at the time the standard was issued.

1.4.1 Unless otherwise specified, the provisions of this standard shall not apply to facilities, equipment, structures, or installations that existed or were approved for construction or installation prior to the effective date of the standard. Where specified, the provisions of this standard shall be retroactive.

1.4.2 In those cases where the authority having jurisdiction determines that the existing situation presents an unacceptable degree of risk, the authority having jurisdiction shall be permitted to apply retroactively any portions of this standard deemed appropriate.

1.4.3 The retroactive requirements of this standard shall be permitted to be modified if their application clearly would be impractical in the judgment of the authority having jurisdiction, and only where it is clearly evident that a reasonable degree of safety is provided.

1.5 Equivalency. Nothing in this standard is intended to prevent the use of systems, methods, or devices of equivalent or superior quality, strength, fire resistance, effectiveness, durability, and safety over those prescribed by this standard.

1.5.1 Technical documentation shall be submitted to the authority having jurisdiction to demonstrate equivalency.

1.5.2 The system, method, or device shall be approved for the intended purpose by the authority having jurisdiction.

Chapter 2 Referenced Publications

2.1 General. The documents or portions thereof listed in this chapter are referenced within this standard and shall be considered part of the requirements of this document.

2.2 NFPA Publications. National Fire Protection Association, 1 Batterymarch Park, Quincy, MA 02169-7471.

NFPA 10, *Standard for Portable Fire Extinguishers,* 2013 edition.
NFPA 140, *Standard on Motion Picture and Television Production Studio Soundstages, Approved Production Facilities, and Production Locations,* 2013 edition.
NFPA 1123, *Code for Fireworks Display,* 2014 edition.

2.3 Other Publications.

2.3.1 ASME Publications. American Society of Mechanical Engineers, Three Park Avenue, New York, NY 10016-5990.

Boiler Pressure Vessel Code, 2013.

2.3.2 Other Publications.

Merriam-Webster's Collegiate Dictionary, 11th edition, Merriam-Webster, Inc., Springfield, MA, 2003.

2.4 References for Extracts in Mandatory Sections.

NFPA 1126, *Standard for the Use of Pyrotechnics Before a Proximate Audience,* 2016 edition.

Chapter 3 Definitions

3.1 General. The definitions contained in this chapter shall apply to the terms used in this standard. Where terms are not defined in this chapter or within another chapter, they shall be defined using their ordinarily accepted meanings within the context in which they are used. *Merriam-Webster's Collegiate Dictionary*, 11th edition, shall be the source for the ordinarily accepted meaning.

3.2 NFPA Official Definitions.

3.2.1* Approved. Acceptable to the authority having jurisdiction.

3.2.2* Authority Having Jurisdiction (AHJ). An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

3.2.3 Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

3.2.4* Listed. Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

3.2.5 Shall. Indicates a mandatory requirement.

3.3 General Definitions.

3.3.1 Accumulator. A container or piping that holds a predetermined volume of fuel that is ready for use in a flame effect.

3.3.2 Area.

3.3.2.1 *Hazard Area.* The area made hazardous by the operation of the flame effect.

3.3.2.1.1 Accessible Hazard Area. That area made hazardous by the flame effect that is normally accessible to a person without the deliberate use of an additional means of access that is not normally in place.

3.3.2.2 *Holding Area.* An area where flame effect material or loaded flame effect devices are held prior to use.

3.3.2.3 *Storage Area.* An area where flame effect material or flame effect devices are stored prior to use or movement to a holding area.

3.3.3* Arm. That sequence of control system functions for the establishing of a source of ignition that must be complete and verified immediately before the firing of the flame effect.

3.3.4 Assistant. A person who works under the supervision of the flame effect operator.

3.3.5 Cast Members. Performers involved in a production involving the use of flame effects that may or may not be employees. (Many amusement employees are also referred to as "cast members.")

3.3.6 Direct Ignition. An automatic or manual ignition system that ignites fuel without a pilot.

3.3.7 Emergency Stop [Emergency Shutdown (ESD) System]. A circuit or other mechanism that, when actuated, results in the complete shutdown and extinguishment of all flame effects that are controlled by it.

3.3.8* Enable. The final set of control system functions that must be verified to be in a specific control mode immediately before the arming and firing of a flame effect may be implemented.

3.3.9 Enable Button. The control operator that is manually actuated by the operator prior to and during the arming and firing of the effect.

3.3.10 Fail-Safe. A state or an attribute of a system such that every single point failure in the system results in all controlling parts of the system with the ability to do harm to humans, animals, or equipment being disconnected from all sources of power and stored energy at the primary disconnect point.

3.3.11* Fire. The sequence of control system functions that result in the deliberate release of fuel for ignition.

3.3.12 Flame Effect. The combustion of solids, liquids, or gases utilizing atmospheric oxygen to produce thermal, physical, visual, or audible phenomena before an audience.

3.3.12.1 ***Automatic Flame Effect.*** A flame effect that is supervised and fired by an automatic control system.

3.3.12.2* ***Hybrid Flame Effect.*** A flame effect that is used in combination with a pyrotechnic material or device.

3.3.12.3 ***Manual Flame Effect.*** A flame effect that is operated manually without the use of an automatic control system.

3.3.12.4 ***Portable Flame Effects.*** Flame effects that are designed and installed, either in a permanent or temporary installation, and that are designed to move or be moved in the course of operation or installation.

3.3.13 Flame Effect Appliance. The complete assembly of components and devices that controls and generates a flame effect.

3.3.14 Flame Effect Burner. A burner designed to produce specific sizes and configurations of flames for flame effects.

3.3.15 Flame Effect Material. Any solid, liquid or gas fuel, or combination thereof, that requires the addition of oxygen in order to initiate and maintain combustion.

3.3.16 Flame Effect Operator. The single person with overall responsibility for flame effect operations and safety.

3.3.17 Flame Effect Safety Controller. A control system that is part of a flame effect appliance that is used to prove that the source of ignition is present (“flame safeguard control”).

3.3.18* Flame Effect System. The complete assembly of interconnected components, devices, and/or appliances that provides all of the functions necessary to fuel, monitor, supervise, generate, and control flame effects, including the emergency shutdown of the flame effects and, where necessary, the monitoring of external conditions that affect operation.

3.3.19* Flame Effect Systems, Classifications.

3.3.19.1 ***Group I Flame Effect.*** An attended, manually controlled flame effect.

3.3.19.2 ***Group II Flame Effect.*** An individual or group flame effect designed for unattended operation that is temporarily or permanently installed outside any structure.

3.3.19.3 ***Group III Flame Effect.*** An attended, temporarily installed flame effect for a specific production with limited operation and fixed time for removal.

3.3.19.4 ***Group IV Flame Effect.*** A large individual or group flame effect that is permanently installed inside or outside any structure designed for unattended operation without a main show supervisory control system.

3.3.19.5 ***Group V Flame Effect.*** A large individual or group flame effect that is temporarily or permanently installed inside or outside any structure and is designed for intermittent or continuous operation under the supervision of a main show control system but without full-time supervision by a technician.

3.3.19.6 ***Group VI Flame Effect.*** A large individual or group flame effect that is temporarily or permanently installed inside or outside any structure and is designed for intermittent operation under the supervision of a main show control system and a technical director, with cast members in close proximity to the effect at the time of operation.

3.3.19.7 ***Group VII Flame Effect.*** An individual flame effect that can be temporarily or permanently installed inside or outside any structure that, due to its unique operating requirements, does not fit into any other classification.

3.3.20 Hybrid Flame Effect. See 3.3.12.2.

3.3.21 Installation, Term of.

3.3.21.1 ***Permanent Installation.*** An installation of flame effects for which the governing use permit has a duration longer than 180 days.

3.3.21.2 ***Temporary Installation.*** An installation of flame effects for which the governing use permit has a duration of 180 days or less within a twelve-month period in a single venue.

3.3.22* Performer. Any person active in a performance during which pyrotechnics are used and who is not part of the audience or support personnel. [**1126,** 2016]

3.3.23 Permit. A document issued by the AHJ for the purpose of authorizing performance of a specified activity. Unless otherwise specified, the word *permit,* when used in this document, refers to a use permit.

3.3.23.1 ***Use Permit.*** A document issued by the AHJ for the purpose of authorizing the use of specific flame effects in a specific venue on a specified date and time or within a specified period.

3.3.24 Plan.

3.3.24.1 ***Design Plan.*** The plan for a flame effect appliance or design that presents the design criteria and/or assumptions used in the design, along with complete design information.

3.3.24.2 ***Flame Effect Plan.*** The document that is used to convey to the AHJ the information needed to evaluate the flame effect for the purpose of applying for a permit.

3.3.25* Primary Safety Control. A control with a sensor that is directly responsive to the ignition device attributes necessary for the safe operation of the effect.

3.3.26 Rated. A description of performance derived from testing or evaluation that guides appropriate selection, installation, and use of equipment that is not listed.

3.3.27* Safety Shutdown (Lockout). The safe shutdown of the flame effect in the event of the actuation of any flame effect primary safety control or limit switch.

3.3.28 Safety-Critical. The failure of a device, component, system, or mechanism, which results in a situation that is immediately dangerous to life, health, or property.

3.3.29* Supervisory Control System. A manual or automatic control system that supervises the operation of the flame effect.

3.3.30* Support Personnel. Any individual who is not a performer or member of the audience. [**1126,** 2016]

3.3.31 Valve.

3.3.31.1 ***Accumulator Charge Valve.*** A valve used to control the flow of fuel into an accumulator.

3.3.31.2 ***Effect Valve.*** The last fuel shutoff valve before the flame effect burner.

3.3.31.3 ***Safety Shutoff Valve.*** A fast-closing valve that automatically and completely shuts off the fuel supply in response to a normal or safety shutdown.

3.3.31.4 ***Vent Valve.*** A normally open, power-closed valve, normally located between the two safety shutoff valves.

3.3.32* Venue. The property, facility, building, or room within a building where flame effects are used, intended to be used, or are prohibited.

Chapter 4 Holding Areas for Flame Effect Materials and Devices

4.1* General. All flame effect materials and devices not connected for use shall be stored in accordance with applicable codes and standards and any state and local regulations.

4.2 Holding Areas. All flammable flame effect materials and loaded devices that have been removed from storage areas in anticipation of use shall be stored in a holding area acceptable to the authority having jurisdiction.

4.2.1 Quantity Limitations.

4.2.1.1 The maximum quantity of flammable flame effect materials and loaded devices stored in a holding area shall be that quantity used in one day.

4.2.1.2 Quantities of flammable flame effect materials and devices in excess of those used in one day shall be permitted to be stored in holding areas with the approval of the authority having jurisdiction.

4.2.2 Flammable flame effect materials and loaded devices in holding areas shall be secured or supervised continuously by an attendant trained in emergency response procedures.

Chapter 5 Permit and Approval Requirements and Terms of Installation

5.1 Permit Requirements.

5.1.1* Permit Required. Except when otherwise required by the jurisdiction, a use permit shall be required for the use of flame effects before an audience.

5.1.2* Terms of Installation.

5.1.2.1 Permanent Installation. An installation of flame effects for which the governing use permit has a duration longer than 180 days shall be considered a permanent installation.

5.1.2.2 Temporary Installation. An installation of flame effects for which the governing use permit has a duration of 180 days or less within a 12-month period in a single venue shall be considered a temporary installation.

5.1.3 Use Permits.

5.1.3.1 A use permit shall authorize the use of only the number and types of flame effects in the venue as specified in the flame effect plan, as described in Section 5.3.

5.1.3.2 Use permits shall have a specified expiration date.

5.1.3.2.1 Use permits for temporarily installed flame effects shall specify the date(s) and time(s) of use and the expiration date of the permit.

5.1.3.2.2 Use permits for permanently installed flame effects shall specify the duration and expiration date of the permit.

5.1.3.3 Any activity authorized by the use permit shall be conducted by the permittee or the permittee's agents or employees in compliance with all requirements of this standard applicable thereto and in accordance with the approved plans and conditions.

5.2 Approval Requirements.

5.2.1 Prior Approval Required. Other than during the flame effect demonstration, as described in Section 5.4, the use of all flame effects shall be first approved by the authority having jurisdiction (AHJ).

5.2.1.1* Hybrid flame effects shall meet the requirements of 5.2.1.1.1 and 5.2.1.1.2.

5.2.1.1.1 That portion of the hybrid flame effect that is governed by NFPA 160 shall meet all of the requirements of NFPA 160.

5.2.1.1.2 That portion of the hybrid flame effect that is governed by NFPA 1126 shall meet all of the requirements of NFPA 1126.

5.2.2 Approval of Flame Effect Plan. A plan for the use of flame effects shall be submitted to the AHJ for approval.

5.2.2.1 After a flame effect plan has been approved, the plan shall be maintained to be readily accessible at the venue and shall be subject to inspection as specified by the AHJ.

5.2.2.2* If any addition or modification of flame effects to that described in the approved plan is made, that addition or modification shall be approved by the AHJ prior to use of the modified flame effects.

5.2.2.3 In the case of a hybrid flame effect, the plan shall identify those portions of the flame effect that require compliance with NFPA 160 and those portions that require compliance with NFPA 1126.

5.3* Content of Flame Effect Plans.

5.3.1 Flame Effect Plan Requirements.

5.3.1.1 The plan for the use of flame effects shall be submitted in writing or other form acceptable to the authority having jurisdiction.

5.3.1.2* The plan shall include the following:

(1) The name of the person, group, or organization responsible for the production

(2) The dates and times of the production
(3) The location of the production
(4) The flame effect classification
(5) A site plan showing the following:
    (a) A narrative description of the flame effect
    (b) The location of flame effect devices to be fired and their controls and control sequence
    (c) The area affected by the flame effect device
    (d) The location of the audience
    (e) The fuels used and their estimated consumption
    (f) Air for combustion and ventilation for indoor effects
    (g) Flammable materials piping
    (h) Storage and holding areas and their capacities
    (i) Supplemental fire protection features
    (j) Emergency response procedures
    (k) Means of egress
(6) A current material safety data sheet (MSDS) for the materials (fuels) consumed in the flame effect
(7) Documentation that the combustible materials used for construction of the flame effects have been rendered flame retardant
(8) The name of the effect operator

5.3.2 The operator shall make operating instructions for flame effects available to the authority having jurisdiction.

5.3.3 The plan shall be reviewed with the authority having jurisdiction, flame effects operator, and building owner/representative prior to the production, to ensure coordinated response in the event of an emergency.

5.4 Flame Effect Demonstration.

5.4.1* When required, a walk-through and a representative demonstration of the flame effects shall be provided to the authority having jurisdiction before flame effects are approved.

5.4.2 The demonstration shall be scheduled with sufficient time to allow resetting of the flame effects prior to the arrival of the audience.

5.5 Interruption of Fire Protection and Life Safety Systems During Flame Effect Demonstrations and Operations. Fire protection and life safety systems shall not be permitted to be interrupted during the operation of flame effects.

5.5.1 Portions of fire protection and life safety systems shall be permitted to be interrupted during the operation of temporary indoor flame effects when the following conditions are met:

(1) Approval of the authority having jurisdiction is received.
(2) Approval of the owner or owner's agent is received.
(3)* An approved fire watch capable of directing the operation of all fire protection and life safety systems installed in the building is present.

5.5.2 Fire protection and life safety systems shall be permitted to be interrupted during the operation of permanently installed indoor flame effects only for initial acceptance of the system.

Chapter 6 Documentation of Flame Effects

6.1 General.

6.1.1 All flame effect devices and materials shall have drawings, manuals, or written descriptions to describe the type of item and performance specifications of the flame effect created.

6.1.2 This documentation shall be on site and available to the authority having jurisdiction.

6.2 Operating Procedures.

6.2.1 All flame effects shall have written operating instructions, including start-up, show operations, normal shutdown procedures, and emergency shutdown procedures.

6.2.2 Operating instructions shall be available to the operator.

Chapter 7 Use of Flame Effects

7.1 Testing and Evaluation.

7.1.1 Flame effects shall be tested to verify that they operate in accordance with their designs.

7.1.2* Flame effects shall be evaluated to verify that spectators, performers, support personnel, and the operator are not exposed to a hazardous situation when the flame effects are activated as designed or anticipated.

7.1.3 On an interval acceptable to the authority having jurisdiction, flame effects shall be inspected for normal and safe operating condition and retested for operation as designed and anticipated.

7.1.4 Documentation of the testing and evaluation shall be permitted to be prepared by a third party acceptable to the authority having jurisdiction.

7.1.5 The documentation shall be made available to the authority having jurisdiction as a part of the application for approval of the effect.

7.2 Housekeeping. The premises where flame effect devices are installed or fired shall be maintained in a neat and orderly condition.

7.3 Site Inspection. The flame effect operator shall inspect all areas of the site where flame effect materials and devices are ignited before start-up and after shutdown.

7.4 Smoking.

7.4.1 Smoking shall be prohibited in the area where fuels used in flame effects are present.

7.4.2 Smoking by performers as part of the performance shall be permitted where approved by the authority having jurisdiction.

7.5 Rehearsal and Pre-Show Operations.

7.5.1 The flame effect operator shall advise all performers and support personnel that they are exposed to a potentially hazardous situation when performing or otherwise carrying out their responsibilities in the vicinity of a flame effect.

7.5.2 Performers and support personnel familiar and experienced with the flame effects being used shall be permitted to be in the area of a flame effect, but only voluntarily and in the performance of their duties.

7.6 Show Operations. Show operations shall be in accordance with the plan approved by the authority having jurisdiction.

7.7 Post-Show Operations. Post-show operations shall be in accordance with the plan approved by the authority having jurisdiction.

7.7.1 Fire and life safety systems that have been interrupted shall be restored immediately after completion of the flame effect.

7.7.2 When restoration of fire and life safety systems is necessary, it shall be conducted by a person trained in the operation of all aspects of the systems.

7.8 Maintenance. Flame effect systems shall be maintained to design specifications.

7.9 Emergency Operations. Emergency operations shall be in accordance with the plan approved by the authority having jurisdiction.

7.10 Protective Clothing.

7.10.1 The flame effect performers, operators, and assistants shall be protected by clothing or other means suitable for their exposure to flame effects.

7.10.2 Protective clothing requiring fire resistance shall be tested and demonstrated to be flame retardant, and documentation shall be furnished to the authority having jurisdiction upon request.

7.10.3 Bare skin (naked) shall be permitted when the illusion of danger is implicit in the visual effect desired by the performer.

7.11 Security.

7.11.1 A means shall be provided to render installed flame effect systems inoperative when not in use.

7.11.2 Portable flame effects shall be stored and secured when not in use.

Chapter 8 Flame Effect Operator

8.1* Operator Qualifications.

8.1.1 The operator of any flame effect shall understand and be familiar with the operating manual or instructions.

8.1.2 The operator shall demonstrate competency by experience and training or by holding a license acceptable to the authority having jurisdiction.

8.2 Operator Responsibilities. The flame effect operator shall be responsible for storage, setup, operations, and teardown of all flame effect materials, devices, equipment, systems, and supervision of assistants.

8.3 Substance Abuse and Safety. No person shall use or handle flame effect materials or devices while under the influence of the following:

(1) Intoxicating beverages
(2) Narcotics or controlled substances
(3) Prescription drugs and/or nonprescription drugs that impair judgment

8.4* Minimum Age. All flame effect operators shall be at least 21 years of age.

Chapter 9 System Components, Flame Effect Control Systems, and Design

9.1 General Requirements for Flame Effect Control System Design.

9.1.1 All flame effect control systems shall be designed and installed to prevent accidental firing and unintentional release of fuel.

9.1.2 All Group II through Group VII control systems shall be designed to ensure against accidental firing by providing at least a removable activator, keyswitch, or coded arming system in which no control power can be applied to any control system unless the operator intentionally does both of the following:

(1) Deliberately applies control power
(2) Enables or arms the control system

9.1.3 Control System Attendance Requirements.

9.1.3.1 Any Group III, Group VI, or Group VII flame effects control systems shall not be left unattended while connected to a fuel source.

9.1.3.2 Control systems that are disconnected from their power source or de-energized by means of a removable activator, keyswitch, or coded arming system shall be permitted to be left unattended while connected to a fuel source.

9.1.4 Control System Operation.

9.1.4.1 All flame effect control systems shall be designed to implement the following functions:

(1) Emergency stop capability
(2) Fuel management
(3) Controlled enabling of flame effect
(4) Controlled arming of flame effect
(5) Controlled and repeatable firing of flame effect

9.1.4.2 The flame effect plan submitted for approval to the authority having jurisdiction shall indicate the means of providing for these requirements.

9.1.5 Flame effect control system components shall be listed.

9.1.5.1 Where listed devices are not available, approved devices shall be permitted.

9.1.6 Control system components and protective devices, including sensors, valves, and switches, shall be located so that they are protected against physical damage and tampering, and so that they can be serviced and maintained.

9.2* Specific Requirements for Flame Effect Control System Design and Operation, by Group. Control systems for each flame effect group shall be in accordance with Table 9.2.

9.3 Implementation of the Required Control Functions.

9.3.1* Emergency Stop.

9.3.1.1 One of the following conditions shall be met prior to the use of flame effects:

Table 9.2 Group Control Functions Required

Flame Effect Group	Control Type	Minimum Control Requirements
I	Manual controls	1. No automatic controls shall be required.
II	Automatic controls	1. Ignition supervision shall be provided. 2. Automatic shutoff shall follow failure.
III	Automatic controls	1. Manual operation of the effect valve shall be permitted. 2. If the operator cannot confirm the pilot or direct ignition source for the flame special effect, a primary safety control shall be installed. 3. Two fuel shutoff valves, one of which will be a safety shutoff valve, shall be provided and installed in series.
IV	Automatic controls	1. Primary limit device(s) shall be installed as required. 2. A fuel supervisory station shall be installed with fuel pressure limit switches to control the supervisory station valves. 3. Each flame effect burner shall be equipped with a primary safety control and an effect valve. 4. A flame effect safety control system that is capable of safely operating the entire flame effect consistently for repeated cycles shall be used.
V	Automatic controls	1. The requirements for Group IV shall apply. 2. A flame effect safety control system that is capable of safely operating the entire flame effect consistently that is sequenced by the main control system shall be used. The flame effect safety control system shall maintain all of its internal safety features, with the interface between the flame effect control system and the main show control system limited to those commands and status indicators that cannot alter or override the flame supervisory system control logic.
VI	Automatic controls	1. The requirements for Group V shall apply. 2. Where cast members are in close proximity to the flame effect, the flame effect shall be under the active control of a main show control system and a fail-safe positive manual enable (PME).
VII	Manual or automatic controls	1. Controls shall be as recommended by the designer and acceptable to the authority having jurisdiction.

(1) Approval of a plan to extinguish the flame effect as required in 9.3.1.4
(2) Approval of a supervisory control system for the emergency stop and complete shutdown of the flame effect and any interrelated safety-critical system as required in 9.3.1.5

9.3.1.2 Interrelated safety-critical system and flame effect control system safety considerations shall extend to safety-critical effects, allied equipment, and other proximate equipment to avoid additional or contributory hazards.

9.3.1.3 Where the hazards described in 9.3.1.2 exist, the effects safety controller shall have a direct validated means of confirming the status or other information from the other systems before the safety-critical effect is enabled or triggered.

9.3.1.4 Manually controlled flame effects (Group I and manually controlled Group VII) shall have a plan for the emergency stop and complete shutdown of the operation of the effects through one or more of the following:

(1) Manual fuel shutoff valve(s)
(2) Manual turn-off of control power
(3) Fire containment devices
(4) Other devices acceptable to the authority having jurisdiction

9.3.1.5 Automatically controlled flame effects (Group II through Group VI and automatically controlled Group VII) shall have provisions for the emergency stop and complete shutdown of the operation of the effects installed according to the following criteria:

(1) The flame effect control system shall not be capable of operation unless the emergency stop is reset.
(2) The actuation of the emergency stop shall bring the flame effect control system to a safe state.
(3) The emergency stop shall require manual reset.
(4) The emergency stop shall actuate both manually and automatically upon the detection of an unsafe condition, including power failure.
(5) The emergency stop shall be fail-safe.
(6)* The emergency stop shall be automatically actuated when a monitored condition exceeds a preset limit of operation.

9.3.1.6 Manual Emergency Stop Control Stations.

9.3.1.6.1 Manually operated emergency stop control stations shall be clearly identified and placed in accessible locations and shall maintain the actuated state until manually reset.

9.3.1.6.2 Operation of a manual emergency stop station shall actuate the emergency stop.

9.3.2 Fuel Management.

9.3.2.1 The fuel supply for the operation of the flame effect shall be available only during operation.

9.3.2.2 Fuels not provided through a central distribution system and that are supplied to the flame effect shall be limited to that amount necessary for operation.

9.3.2.3 Minimum tank size for liquefied flammable gas flame effects shall be determined by the surface area required to prevent reduced fuel delivery to the burner during the effect.

9.3.2.4 Fuel Delivery.

9.3.2.4.1 Fuels delivered through a central distribution system shall be in accordance with the following:

(1) A manual fuel shutoff valve shall be installed as follows:
  (a) It shall be installed in an accessible location at the point of delivery and upstream of any other flame effect control system components that, when closed, will shut off all fuel supplied to the flame effect control system.
  (b) Where the point of delivery is outside a building containing the flame effect control system, the valve shall be located outside of the building.
(2) The following shall apply to fuel pressure:
  (a) Where low fuel pressure could cause the flame effect control system to malfunction, devices to provide low-fuel-pressure supervision shall be installed.
  (b) Where high fuel pressure could cause the flame system to malfunction, devices to provide high-fuel-pressure supervision shall be installed.
(3)* A supervisor station shall be installed and shall meet the following criteria:
  (a) It shall be installed downstream of the manual fuel shutoff valve.
  (b) It shall shut off all fuel supplied to the flame effect control system when closed.
  (c) When opened during the enable process, it shall be held open by a maintained signal from the flame effect control system.

9.3.2.4.2 The supervisor station shall be provided with a means to test the seat-tightness of the shutoff valve at the operating pressure.

9.3.2.5 Effect Valve.

9.3.2.5.1 Each flame effect shall be provided with an automatic fuel shutoff valve (the effect valve), installed upstream of the burner.

9.3.2.5.2 The effect valve shall shut off all fuel to the burner when closed.

9.3.2.5.3 The effect valve shall be opened only at the time of firing the flame effect and shall be held open by a maintained signal from the flame effect control system.

9.3.2.5.4 The effect valve shall close on loss of the hold-open signal.

9.3.2.6* Systems Using Fuel Accumulators. Fuel accumulators used in flame effect control systems shall meet the following requirements:

(1) Accumulator tanks shall be designed, manufactured, and certified as unfired pressure vessels.
  (a)* Accumulators for use with flammable or liquefied gas shall be designed, manufactured, and tested in accordance with the ASME *Boiler Pressure Vessel Code* or the Department of Transportation for the pressure of the gas in use.
(2)* The volume of fuel stored in an accumulator tank shall be no more than what is required to produce the desired flame effect.
(3) Each accumulator shall have a manual fuel shutoff valve at the connection to the inlet of the tank, and when closed, this valve shall shut off all fuel supplied to the accumulator tank.
(4) An accumulator charge valve that charges the accumulator when opened shall be installed at the connection to the inlet of the tank.
(5) The accumulator shall be charged as close to the time of the actual arming and firing of the effect as is practical.
(6) Each accumulator shall be designed and installed so that the fuel can be safely removed, as follows:
  (a) Accumulators fixed in location shall be provided with a permanently installed means of conveying the fuel to a safe point of discharge.
  (b) Portable accumulators shall be allowed to be moved to a safe location for discharge.
(7) The mixing of air or any other oxidizing media with fuel that creates a flammable mixture within an accumulator tank shall be prohibited.

9.3.3* Controlled Enabling of Flame Effect Control System. All flame effect control systems shall be manually or automatically enabled according to a prescribed sequence of operations outlined in the plan, which prepares the flame effect for subsequent arming and firing.

9.3.3.1 Flame Effect Safety Controller Function.

9.3.3.1.1 A flame effect safety controller shall be used to automatically sequence the enable process, monitor areas of restricted access, and allow, trigger, and request safety-critical action.

9.3.3.1.2 Flame effect control system safety considerations shall extend to other safety-critical effects, allied equipment, and other proximate equipment to avoid additional or contributory hazards.

9.3.3.1.3 In circumstances described in 9.3.3.1.2, the flame effect safety controller shall have a direct validated means of confirming the status or other information from the other systems before the flame effect is enabled.

9.3.3.2* The enable process shall begin with the activation of the control power to the flame effect control system.

9.3.3.3 Fuel Supply and Auxiliary Services.

9.3.3.3.1 Following the activation of the control power, the fuel supply and auxiliary services necessary to the operation of the flame effect control system (compressed air supply, oxidizers, additives, etc.) shall be permitted to be turned on.

9.3.3.3.2 Positive confirmation through the use of an interlock or other device of the fuel supply and each auxiliary service shall be made prior to the continuation of the enable process.

9.3.3.4* Interlocks.

9.3.3.4.1 Interlocks shall be provided in the control system to monitor changes of condition and to automatically implement control system responses to the change of condition.

9.3.3.4.2 Safety interlocks shall be fail-safe.

9.3.4 Controlled Arming of Effect.

9.3.4.1 All flame effects shall be manually or automatically armed prior to any attempt to fire.

9.3.4.2 The arming of the effect shall be manually or automatically monitored and confirmed until the effect is fired.

9.3.4.3 Manual Confirmation of Arming (Group I and Manually Controlled Group VII).

9.3.4.3.1 The flame effect shall be confirmed as armed when the means of ignition can be clearly and directly seen by the operator or assistant(s) firing the flame effect for the entire time that the effect is enabled.

9.3.4.3.2 When the means of ignition cannot be clearly and directly seen by the operator or assistant(s) firing the flame effect for the entire time that the effect is enabled, the confirmation of the arming of that effect shall be done automatically.

9.3.4.4* Automatic Confirmation of Arming (Group II through Group VI and Automatically Controlled Group VII). The flame effect shall be confirmed as armed when a sensor(s) has detected the presence of the means of ignition necessary for the correct operation of the effect through the monitoring of a characteristic unique to the means of ignition.

9.3.4.5 Control sensors and devices used to automatically confirm arming shall operate in the environment where installed.

9.3.4.6 Where cast members or moving set pieces are present in the hazard area immediately before or after the arming and firing of the flame effect, a positive manual enable (PME) shall be required during arming and firing.

9.3.4.7 Ignition Detection Device Function.

9.3.4.7.1 It shall not be possible for an ignition detection device to report the presence of an ignition device or pilot, due to false sensing of ignition devices, pilots, or flame effects other than that ignition device or pilot intended to be sensed by the ignition detection device.

9.3.4.7.2 It also shall not be possible for an ignition detection device to report the presence of an ignition device or pilot due to false sensing of other non-fire-related devices normally present in the local environment including, but not limited to, spark effects, ultraviolet light sources, or effects that generate heat without flame.

9.3.5* Firing of Flame Effects.

9.3.5.1 Flame effects shall only be fired after they have been confirmed as armed following the completion of the enable and arming process and confirmation that the hazard area is clear.

9.3.5.2 If the arming confirmation is lost during the firing process or the hazard area becomes unsafe, the firing of the effect shall be immediately terminated and the effect secured until the problem has been corrected.

9.3.5.3* Monitoring of the Hazard Area Surrounding the Flame Effect.

9.3.5.3.1 That area surrounding each flame effect that is made hazardous by the operation of the effect shall be monitored and confirmed clear and ready for firing, or access to the area shall be supervised by automatic means, or the area shall be made inaccessible, prior to any attempt to fire the effect.

9.3.5.3.2 Other parameters critical to the safety of the flame effect shall also be monitored or supervised.

9.3.5.4* Supervision of the Hazard Area Surrounding the Flame Effect.

9.3.5.4.1 The accessible hazard area shall be under the direct observation of the operator or assistant(s) firing the flame effect for the entire time that the effect is enabled and fired.

9.3.5.4.2 Where the hazard area cannot be seen by the operator or assistant(s) firing the flame effect for the entire time that the effect is enabled, an alternative means of monitoring the area shall be permitted to be used, with the approval of the authority having jurisdiction.

9.3.5.4.3 Use of Enable Buttons.

9.3.5.4.3.1 If all areas of safety concern cannot be seen by a single human operator, as many enable buttons shall be used as are necessary to ensure safety.

9.3.5.4.3.2 Such buttons shall be monitored separately and verified for proper operation by the flame effect control system.

9.3.5.5 Firing. The design of the flame effect control system shall prevent the firing of any flame effect except on the deliberate positive action of an operator or on the verification by the automatic control system of correct enabling and arming of the effect.

9.3.5.5.1 Manual Firing of Flame Effects. It shall be the responsibility of the operator to verify the correct enabling and arming and the safety of the hazard area prior to the manual firing of the effect.

9.3.5.5.2 Automatic Firing of Flame Effects.

9.3.5.5.2.1 The operating power for firing any flame effect shall originate from the flame effect control system and only be supplied under the supervision of all limits, interlocks, and ignition-monitoring devices present for the safe and reliable operation of the flame effect.

9.3.5.5.2.2 All effect valves shall be permitted to be opened only by a maintained firing signal from the flame effect control system and shall automatically close on loss of signal.

9.3.6 Post-Operation Securing. Immediately following the firing of any flame effect, the enable and arming signals shall be removed, all fuel and auxiliary services shall be secured without going through the sequence of operation specified in 9.3.5.5, and a visual inspection of all effect hazard areas shall be completed prior to confirmation that the flame effect control system is secure.

Chapter 10 System Installation and Testing

10.1 General.

10.1.1 Flame effects shall be tested to verify that they operate in accordance with the flame effect control system design.

10.1.2 Documentation of the testing shall be provided by the manufacturer or fabricator.

10.2 Pressure Testing and Inspection of Piping. Where flame effect systems use piping, such piping shall be pressure tested in accordance with the requirements of the authority having jurisdiction.

10.2.1 The complete piping system with all accessories in place shall be pressure tested at no less than the system operating pressure.

10.2.2 Pressure Test Procedures.

10.2.2.1 System pressures shall be recorded together with the temperature and the atmospheric pressure.

10.2.2.2 Pressure testing of reassembled flame effect piping systems designed to be separated into subassemblies shall be permitted to be tested at system operating pressure, with leak detection using a noncorrosive leak-detecting solution, or other means acceptable to the authority having jurisdiction, at the reconnected joints.

10.3 Temperatures of Components.

10.3.1 Temperatures of components that are used in the fabrication of a flame effect control system shall not exceed the rated temperature limits of the component during sustained operation of the flame effect.

10.3.2 Temperatures of components subject to the heat of the flame effect shall be determined while the flame effect is being operated at its maximum design cycle rate during the acceptance test required by Section 10.1.

10.3.2.1 The temperatures shall be observed until a maximum or stable reading has been attained.

10.3.2.2 The temperatures attained shall not exceed the rated temperatures for the components.

10.3.3 Temperatures of Surroundings.

10.3.3.1 Temperatures of combustible materials subject to the heat of the flame effect shall not exceed 117°F (47.2°C) above the ambient temperature after equilibrium temperatures are attained.

10.3.3.2 The temperatures shall be observed until a maximum or stable reading has been attained.

Chapter 11 Fire Protection Provisions

11.1 General. The wide range in size, arrangement, and location of flame effects covered by this standard shall preclude the inclusion of detailed fire protection provisions that are applicable to all flame effects.

11.2 Evaluation for Permanently Installed Flame Effects.

11.2.1* Where required by the authority having jurisdiction, a fire hazards evaluation shall be conducted for permanently installed flame effects to be used at a venue for a performance.

11.2.2 The evaluation in 11.2.1 shall be coordinated with the building owner, the flame effect operator, and the authority having jurisdiction.

11.3* Additional Fire Safety Provisions for Temporary Installations.

11.3.1 Where determined by the authority having jurisdiction that a need for fixed or additional fire protection equipment or standby fire safety personnel exists, such equipment or personnel shall be provided.

11.3.2 Four or more fire extinguishers of the proper classification and size as approved by the authority having jurisdiction shall be readily accessible while the flame effects performance is being conducted.

11.3.2.1 In all cases, at least two pressurized water, Class 2-A extinguishers and two Class 10-BC extinguishers shall be provided, in addition to those required by NFPA 10, for the building.

11.3.2.2 The extinguishers shall be placed so that at least one each is located on opposing sides of the performance where flame effects are used.

11.4 Standby Fire Safety Personnel Requirements.

11.4.1 Where required by the fire hazards evaluation or the authority having jurisdiction, standby fire safety personnel shall be present along with operational supplemental equipment.

11.4.2 Standby fire safety personnel shall have a working knowledge of the supplemental fixed or portable fire-fighting equipment used in the area of the flame effects.

11.4.3 Standby fire safety personnel shall have a means of communication or of transmitting an alarm during the operation of flame effects.

Annex A Explanatory Material

Annex A is not a part of the requirements of this NFPA document but is included for informational purposes only. This annex contains explanatory material, numbered to correspond with the applicable text paragraphs.

A.1.1 This document details how to control the use of flame effects. The issue of permitting or prohibiting the use of open flames before an audience is in the scope of a code such as NFPA *101*, The *Life Safety Code* has traditionally prohibited open flames within assembly occupancies.

A.1.3.1 The circumstances of each show or attraction can be unique and can require individual evaluation when determining the need for protective systems. Factors such as the experience and qualifications of the operations and maintenance personnel, clearance distance between show elements and nonparticipants, visual conditions, and magnitude of the potential hazards are to be weighed in the development and presentation of the production.

A.1.3.3(1) As covered in NFPA 1126.

A.1.3.3(2) For information on the use of pyrotechnic special effects before an audience, see NFPA 1126.

A.1.3.3(3) For information on the storage of flammable and combustible liquids, see NFPA 30. For information on the storage of flammable gases, see NFPA 55, and NFPA 58.

A.1.3.3(7) For information on the manufacture, transportation, or storage of model or high power rocket motors, see NFPA 1125. For information on the sale or use of model or high power rocket motors, see NFPA 1122 and NFPA 1127.

A.1.3.3(11) For information and guidance on ground-based effects in air shows, refer to International Council on Air Shows (ICAS) *Guidelines for the Use of Pyrotechnics and Special Effects at Air Shows* and NFPA 495.

A.1.3.4 This standard contains user requirements for the performance, use, or installation of flame effects. User requirements are those that apply to users of the product and specify when, where, and how a product is used.

Unlike this standard, a product standard contains performance, testing, and third-party certification requirements, and can contain design requirements, for a specific product, such as a flame effect appliance. Third-party certification includes the requirements for the testing, labeling, listing, follow-up, and quality assurance programs by which a product is certified as being compliant with a specific standard from a certification organization. Product standards should be written, to the extent possible, such that the product is evaluated and tested for compliance with minimal or no judgmental decisions and with specific pass/fail requirements and a designated test method to evaluate the performance. NFPA 160 does not meet these requirements, nor is it intended for use as a product standard.

A.3.2.1 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

A.3.2.2 Authority Having Jurisdiction (AHJ). The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A.3.2.4 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A.3.3.3 Arm. In a manually operated system, the enabling, arming, and firing functions are provided directly through the actions of the flame effect operator or assistant. *Arm* means supplying a source of ignition and verifying its presence, such as with manual ignition of a pilot, flammable liquid, or flammable solid.

A.3.3.8 Enable. In a manually operated system, the enabling, arming, and firing functions are provided directly through the actions of the flame effects operator or assistant. *Enable* means bringing to the site all the equipment, setting it up, and readying it for arming, such as bringing a campfire effect to the stage, verifying that no hazards are present in the area, and connecting all components.

A.3.3.11 Fire. In a manually operated system, the enabling, arming, and firing functions are provided directly through the actions of the flame effect operator or assistant. *Fire* means supplying fuel to the source of ignition, such as by manually opening a valve and verifying that the fuel ignites.

A.3.3.12.2 Hybrid Flame Effect Flame effects that use any of the fuels allowed by this standard but are initiated or directly ignited by means of a pyrotechnic device are common examples of a hybrid flame effect. One example of a hybrid flame effect is one that uses a pyrotechnic device or igniter to provide the initial flame to light a supervised pilot burner, which, when ignited, can be then proven by a conventional flame safeguard or other means. Often this hybrid configuration is used where the pilot burner is in and/or around water or spray, and conventional ignition means have been determined to be unreliable or to utilize voltages or currents that provide a risk of hazard to persons in and around the water. In other instances, this configuration might be used for added reliability, operational integration, or simply for convenience. In any of these instances, the pyrotechnic igniter is used under the requirements of NFPA 1126 and is installed, maintained, and operated to meet the requirements of both NFPA 1126 and the AHJ. The flame effect itself, regardless of the fuel it uses, is designed, installed, maintained, and operated to meet the requirements of both NFPA 160 and the AHJ.

A second example of a hybrid flame effect is one that utilizes a combustible dust, initially aerosolized and propelled out the end of the burner nozzle by a charge of compressed air and ignited as it passes through a field of burning metal sparks generated by yet another pyrotechnic device. Dust or powder fuel is an acceptable flame effect material under this standard. What causes this effect to be classified as a hybrid flame effect is that the pyrotechnic ignition device(s) falls under the purview of NFPA 1126. (Note that if a gas pilot burner or even a burning brand were used to ignite an aerosolized powder, this flame effect would not be considered hybrid and would fall entirely under the scope of NFPA 160.)

A third example is an often-used flame effect that is typically limited to outdoor use and utilizes flammable or combustible liquid as a fuel. This would be an acceptable flame effect material under this standard. The fuel is contained in a nonporous bag and placed inside a suitable open-topped container that serves as a "mortar" or burner nozzle. Upon firing, the liquid is freed from the bag, lifted from the barrel, and aerosolized by means of a substantial black powder lifting charge. A second pyrotechnic device might or might not be used to ensure ignition of the fuel at the mouth of the container. What causes this effect to be classified as a hybrid flame effect is that the aerosolizing and igniting charges fall under the purview of NFPA 1126, or, depending upon the particular composition and quantity of the charge in use, possibly NFPA 1123 or NFPA 495. Additionally, the storage and/or handling of the liquid fuel would be governed by the requirements of NFPA 30. (Note that if a compressed air charge was used to aerosolize the liquid and a gas fired pilot burner or even a burning brand was used to ignite the aerosol, this flame effect would not be considered hybrid and would fall entirely under the scope of NFPA 160.)

A.3.3.18 Flame Effect System. Manually controlled systems might not have interconnected components, devices, and/or appliances that provide all of the functions necessary to fuel, monitor, supervise, generate, and control flame effects, including the emergency shutdown of the flame effects and, where necessary, the monitoring of external conditions that affect operation. The flame effects operator or assistant carries out all the functions described in the definition.

A.3.3.19 Flame Effect Systems, Classifications. Examples of flame effects are as follows:

(1) *Group I.* Where used to give the illusion of danger to a performer, the use of hand-held burning torches, cigarette lighters, candles, matches, lighting paper in an ashtray, jugglers burning batons, fire rings that are jumped through, and other flame effects that are not included in another flame effect group.
(2) *Group II.* Unattended torches, burning urns, and small fires.
(3) *Group III.* An attended, temporarily installed flame effect used by traveling shows and concerts and effects used for limited-duration special events, such as the Olympics. This group also includes a traveling entertainment event that plays various venues, such as (but not limited to) circuses, operas, musicals, stage plays, trade shows, or corporate events. This group effect also includes a non-traveling entertainment event that plays a single venue.
(4) *Group IV.* A burning cabin or bonfire and large single or multiple flaming brazier entrance features used to create a "theme" atmosphere. A standalone-type flame effect control system without any significant control supervision by a main show control system is used.
(5) *Group V.* A simulated building or vehicle explosion that is part of a larger theme-type attraction. The flame effect control system is totally dedicated to the operation of the flame effect elements. The flame effect control system maintains all its internal safety features, with the interface between the flame effect control system and the main show control system limited to those commands and status indicators that cannot alter or override the flame supervisory system control logic.
(6) *Group VI.* A live-action stunt show that is part of a larger theme-type attraction. The flame effect control system is totally dedicated to the operation of the flame effect elements. The flame effect control system maintains all its internal safety features, with the interface between the flame effect control system and the main show control system limited to those commands and status indicators that cannot alter or override the flame supervisory system control logic.
(7) *Group VII.* A fire created as part of an illusion used to make an item or individual disappear.

See Table A.3.3.19 for a list of features included in each flame effect group.

Table A.3.3.19 Features Included in Flame Effect Groups

	Flame Effect Groups						
Features	**I**	**II**	**III**	**IV**	**V**	**VI**	**VII**
Outside	X	X	X	X	X	X	X
Inside	X		X	X	X	X	X
Temporary installation	X	X	X		X	X	X
Permanent installation		X		X	X	X	X
Attended	X		X			X	X
Unattended		X		X	X		X
Visual flame verification	X		X				X
Automatic flame supervision		X		X	X	X	X
Manual fuel controls	X						X
Automatic fuel controls		X	X	X	X	X	X
Main show control					X	X	
Proximate cast			X			X	X

Note: A blank space means that the feature cannot be in the group. An X means that it is a feature of the group.

A.3.3.22 Performer. Performers can include, but are not limited to, actors, singers, musicians, and acrobats. [**1126,** 2016]

A.3.3.25 Primary Safety Control. In the event of ignition failure or loss of flame, the control causes a safety shutdown.

A.3.3.27 Safety Shutdown (Lockout). The flame effect can be restarted only after a manual reset following correction of the abnormal condition.

A.3.3.29 Supervisory Control System. In the case of a manual system, this function might be performed by the flame effect operator or assistant.

A.3.3.30 Support Personnel. Among others, support personnel include the road crew of any production, stage hands, property masters, security guards, fire watch officers, janitors, or any other employee. [**1126,** 2016]

A.3.3.32 Venue. The term *venue* is one that is widely used in the entertainment industry. For the purposes of this standard, the term is to be used to specify the exact area of the property, building, or the room within a building where the use of flame effects is to be allowed. For example, the use of flame effects can be allowable in one specific meeting room of a hotel, but not in another; or in the case of reconfigurable (flexible plan) buildings or rooms, some configurations can be safe for the use of flame effects, but not others.

A.4.1 The following NFPA standards cover storage of flame effect materials:

NFPA 30, *Flammable and Combustible Liquids Code*

NFPA 54, *National Fuel Gas Code*

NFPA 55, *Compressed Gases and Cryogenic Fluids Code*

NFPA 58, *Liquefied Petroleum Gas Code*

NFPA 59A, *Standard for the Production, Storage, and Handling of Liquefied Natural Gas (LNG)*

NFPA *101*, *Life Safety Code*

NFPA 400, *Hazardous Materials Code*

NFPA 1126, *Standard for the Use of Pyrotechnics Before a Proximate Audience*

A.5.1.1 Because permit and approval requirements vary with each jurisdiction, this standard is intended to provide requirements that can be used by the authority having jurisdiction in making sound judgment regarding the safety of the proposed use of flame effects and the qualifications of the flame effect operator.

A.5.1.2 The use of flame effects is governed by a permit, which specifies the date(s) and time(s) or the expiration date of the permit, which, in turn, define the period during which the effects can be used. The length of this period determines the term of installation — that is, whether the flame effect installation is to be considered permanent or temporary. The term of installation is used in this standard as a criterion to classify the flame effects into one of seven groups.

A.5.2.1.1 Where the standards impose different requirements, the most stringent requirement should be the one used, unless otherwise approved by the AHJ.

A.5.2.2.2 There is an inherent danger in the modification of flame effects once the initial commissioning activities are complete. A protective control system could provide protection against events and safety concerns that are not recognized or fully understood by other than the original designers of the system. For others to attempt modifications to a protective system invites the inadvertent elimination of subtle but important safety features of a system.

A.5.3 Measures for control of inadvertent liquefied or gaseous fuel releases, additive system releases, portable component releases, or fire should be coordinated with local emergency-handling agencies, such as fire and police departments.

Information on those hazards not commonly covered in the training programs of emergency-handling agencies should be provided upon request to emergency responders.

The safety of emergency personnel should be considered in the plan.

A.5.3.1.2 See Annex B for guidelines on design of flame effects.

A.5.4.1 The AHJ should invite the local responding fire companies to witness the demonstration to familiarize them with the potential hazards involved.

A.5.5.1(3) A fire watch is a qualified person or persons in attendance during all times when fixed fire protection systems are intentionally taken out of operation and should be acceptable to the authority having jurisdiction. The fire watch should be familiar with the operation of all fire and life safety systems in the building and be able to notify emergency responders.

A.7.1.2 As a guide, the incident radiation from the flame effect should not cause the surface temperature of the exposed skin of a member of the audience to exceed 111°F (44°C), as measured using an infrared surface thermometer or other equivalent means. The operator should have, on site, the instrumentation necessary to verify skin temperature, if requested by the authority having jurisdiction.

A.8.1 There is no substitute for a diligent, capable, well-trained operations and maintenance staff; therefore, operators of equipment involved in safety-critical processes or effects are the primary safety and control element and should have a full understanding of the system, including the possible dangers and the required responses.

A.8.4 The flame effect operator is defined as the person who has overall responsibility for the flame effect. Attendants and assistants can be less than 21 years of age.

A.9.2 In Table 9.2, Group VI, positive manual enable (PME) is sometimes known as “Man in the Loop.”

A.9.3.1 Enabling the safety-critical effect could require coordination of the emergency stop systems of independent subsystems developed by separate vendors or contractors. This requirement applies only when an emergency stop button is pressed. Generally, conditions internal or local to a single subsystem (other than pressing an emergency stop button) that cause an automatic safety shutdown of one subsystem need not cause a shutdown of other subsystems. After a safety shutdown resulting from a pressed emergency stop button, and after the offending button has been reset, individual subsystems can be brought out of the shutdown condition, as long as no emergency stop button remains pressed.

A.9.3.1.5(6) Examples of monitored conditions are as follows:

(1) Loss of purge airflow to electrical enclosures in classified areas
(2) Loss or impairment of required ventilation systems
(3) Detection of flammable gas
(4) Loss of “proof of vacancy” in areas that present a serious hazard to personnel
(5) Loss of proof of the safe state of any valve or other protective device that is required to maintain the protective nature of the system
(6) Detection of a person in an unsafe area
(7) Detection of unsafe environmental conditions
(8) Detection of equipment in an unsafe state, condition, or position
(9) Wind or other weather conditions that create unsafe conditions
(10) System errors that should be addressed or acknowledged prior to a restart of the system

A.9.3.2.4.1(3) As shown in Figure A.9.3.2.4.1(3), an example of a supervisor station can include the following:

(1) Two safety valves in series, each with proof of closure, should be provided in the gas line to the main burners. An automatic vent valve should be provided between the two valves.
(2) Where the automatic vent valve is prohibited by the authority having jurisdiction, two safety shutoff valves in series, each with an interlock switch, supervised by a listed automatic valve proving system, should be provided in the

gas line to the burners. Valve proving should be performed either after every burner shutdown or prior to every burner light-off.

(3) Where flame effect fuel piping systems are subdivided into zones, each zone should be separated from other zones by a zone station. A zone station should consist of a manual fuel shutoff valve at the point of connection to the fuel supply piping and upstream of any other station components, and an automatic zone valve. The zone station shuts off all fuel to or from the flame effect zone when closed. When opened during the enable process, this station should be held open by a maintained signal from the flame effect control system.

The zone valve should automatically close in the event of the loss of the hold-open signal. The zone valve should only be opened as close to the time of the actual arming and firing of the flame effects as is practical. The zone valve should be provided with a means to test the seat-tightness of the valve at operating pressure.

A.9.3.2.6 The operating characteristics of some flame effects require that fuel be released at a rate greater than can be delivered by the fuel supply. To do so requires that quantities of fuel be temporarily accumulated at the location of the effect.

A.9.3.2.6(1)(a) For applications outside of the United States, equivalent national standards can be used.

A.9.3.2.6(2) The standard requires that the amount of fuel in an accumulator tank never be more than what is required to produce the effect. However, that amount deserves some consideration, as producing the desired effect can sometimes require that more fuel be stored in the accumulator than is actually discharged during the effect. Three examples of situations where it is necessary to store more fuel in the accumulator than is actually consumed are as follows:

(1) The creation of perfectly round fireballs — those without a tail — often requires that the effect valve be shut while the gas is still exiting the burner nozzle at relatively high velocity. This means that significant residual pressure is

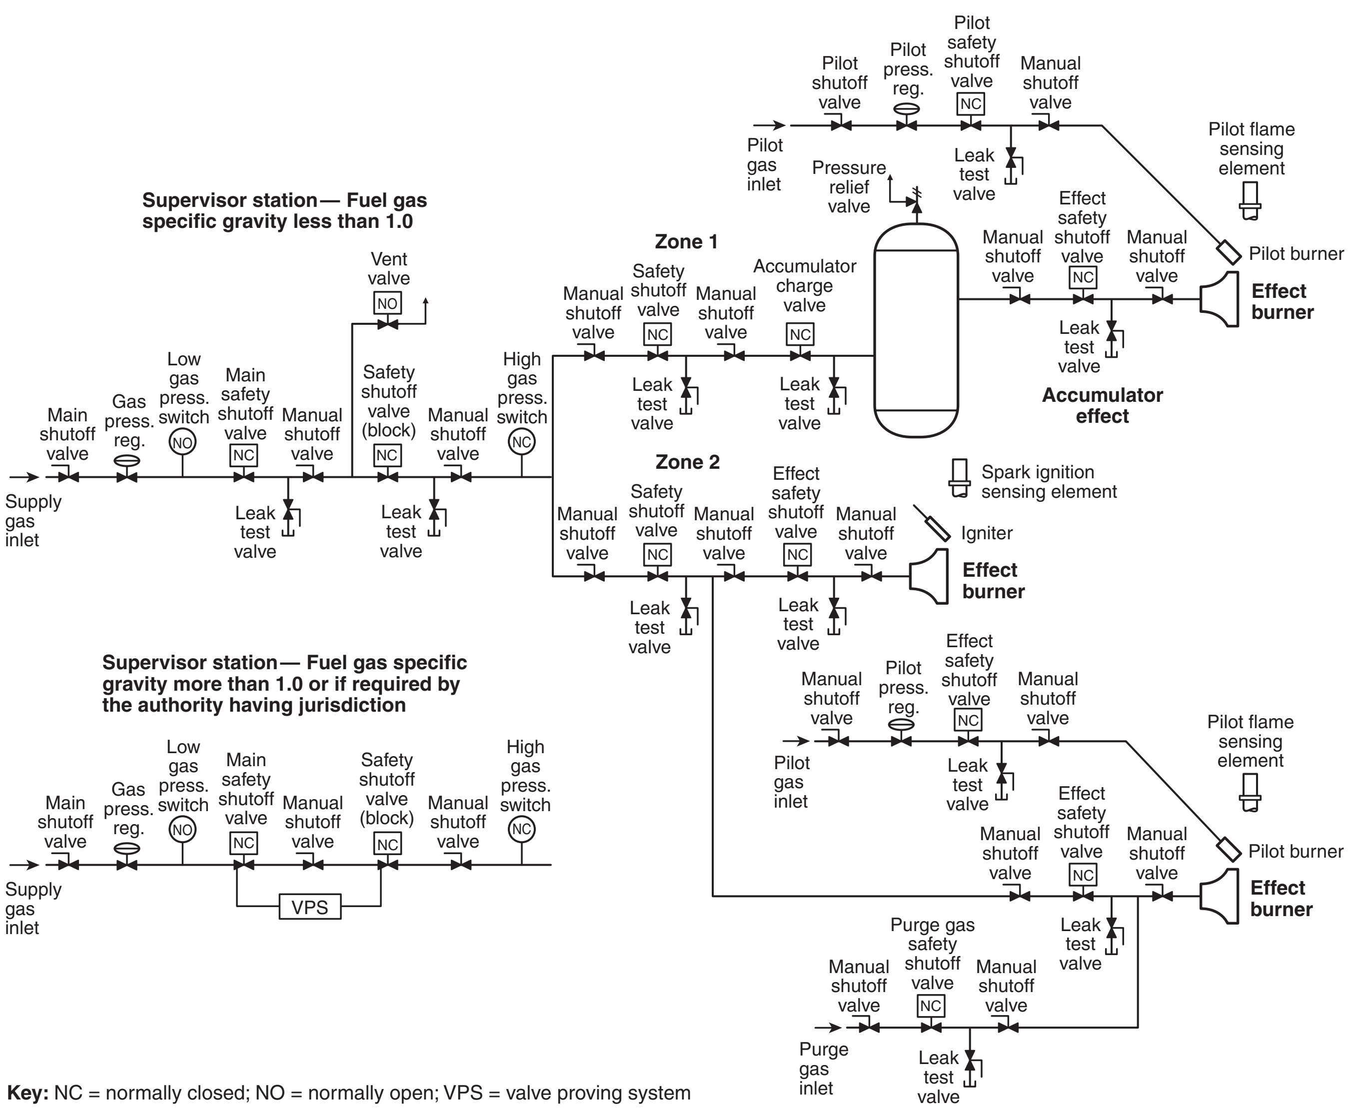

FIGURE A.9.3.2.4.1(3) Example of Various Flame Effect Control and Piping Components.

left in the accumulator after the effect is complete; in other words, to produce round fireballs it is required to have an amount of fuel in the accumulator in excess of that consumed.

(2) Bursts of multiple fireballs or jet flames are often required to be produced rapidly, sometimes without sufficient interval between each discharge to allow the accumulator to recharge. This situation occurs often in temporarily installed or portable flame effect appliances, particularly when the fuel supply is not capable of supporting high flow rates during the charge cycle. In this case, the accumulator must store more fuel than is consumed in a single discharge, although it is expected that the bulk of the fuel will be consumed over the course of a full burst.

(3) It is considered good practice to maintain a fuel-rich atmosphere inside the accumulator at all times, one that is well above the upper flammable limit. In order to do so it is necessary to shut the effect valve before all of the pressure in the accumulator is exhausted, trapping some fuel in the accumulator in excess of the amount consumed.

It is important to realize that even when an accumulator is sized exactly to the amount of fuel to be consumed, there are some situations where the accumulator will be left with an excess of fuel. Take, for example, an accumulator that has been charged, but for any number of reasons — performer off the mark, detected failure of the igniter, and so forth — the flame effect is not discharged. The result is a fully charged accumulator that can or cannot be consumed during the subsequent course of the performance. This scenario points out the necessity of providing each accumulator with a means of venting the fuel to a safe point of discharge, as required in 9.3.2.6(6).

A.9.3.3 Some of the operating parameters that can be enabled or monitored during the enabling of the flame effect control system include the following:

(1) Control power
(2) Main fuel supply
(3) Safety interlocks
(4) Ventilation airflow interlock (where used)
(5) Support services (compressed air, hydraulic pressure, etc.)
(6) Other parameters as required by the authority having jurisdiction

A.9.3.3.2 Where required for operation and maintenance, control systems can have separate sources of control power to allow operation in distinct modes; for example, they can have one source for automatic (normal) operation and a second for limited operation of the flame effects for the purpose of maintenance and testing. Where multiple sources of control power are available, the design of the flame effect control system should meet the following minimum criteria:

(1) One mode of operation should be "off," which should remove all control power from the flame effect control system.

(2) System operation should be such that the selection of one mode of operation disables all other modes of operation. It should not be possible to change from one mode of operation to another without turning all control power off. The flame effect control system should operate safely during the transition from one mode to any other mode of operation.

(3) All control power, regardless of source and mode of operation, should be interrupted by actuation of the emergency stop system. Loss of control power should bring the flame effect system to a safe state.

(4) When a main show control system is used, the status of the control power (mode of operation) should be automatically sent to the show control system at all times. Where a main show control system is used, and the mode of operation is in any mode other than that of normal automatic operation, or "off," the sending of any command from the show control system to the flame effect control system should automatically actuate the emergency stop system and bring the flame effect system to a safe state.

Circumstances for consideration include the following:

(1) Particular position, mode, or state for the proper operation of a safety-critical system.
Example: A fire-breathing dragon that needs to be in a particular position before fire is initiated. Similarly, other set pieces might have to be out of the area of the fire before fire is initiated.
Example: A fire on a set that is on a lift and that is not to be initiated until the lift is confirmed to be in the fully raised position.

(2) Effects on vision or hearing that could prevent the safe operation of systems or the related procedures or operations.
Example: A fog or other atmospheric effects system that could obscure egress routes or interfere with monitoring an effect fire or with taking corrective action in case of an incident.

(3) Conditions that can be confused with conditions or events of the safety-critical system.
Example: Other effect systems that create the appearance of fire, smoke, or heat.

Personal computers, single-board controllers, and other systems that have control capability but that are not routinely used in protective applications should not be used as life safety controllers. Only effect safety controllers should be used to prevent any safety-critical action. Non-effect safety controllers should not be used to allow, trigger, or request safety-critical action unless the signals of these non-effect safety controllers are intercepted and qualified by an effect safety controller that has responsibility for allowing safety-critical actions. Personal computers and single-board controllers can be used in related applications such as the display, logging, and trending of process variables, environmental conditions, status, faults, and other information.

Show controllers, including stage, lighting, pyrotechnics, animation, automation, and audio controllers that are used to control overall show timing relationships or that provide synchronization with audio, lighting, and unrelated effects, should be permitted to provide timing information to a flame effect safety controller but should not directly control safety-critical processes. The flame effect safety protective controller then should use this information, and other safety-related information, to control safety-critical effects.

The flame effect control system that is responsible for control of safety-critical effects should not provide control of general show timing or of non-safety-critical effects, except as follows:

(1) Timing internal to a single effect, such as to create phases or sub-effects, should be permitted to be programmed into the flame effect control system.
(2) The protective flame effect control system should be permitted to provide control of a limited number of small non-safety-critical effects with limited and simple timing needs. In such cases, there should be a division of the safety-critical and non-safety-critical functions of the system.

The purpose of the requirement in 9.3.3.2 is to prevent equipment that is being used for protective control purposes from being utilized for general show control purposes when doing so would partially obscure the protective control purpose of the system, distracting the designers and operators from devoting attention to the safety-critical aspects of the system, which are of primary concern.

A.9.3.3.4 Examples of interlocks that can be included in the flame effect control systems are as follows:

(1) Wind speed and direction
(2) Critical temperatures
(3) Opacity instrumentation
(4) Purge airflow and/or damper positions
(5) Combustion airflow
(6) Position indicator switches for animated figures and sets
(7) Cast position confirmation switches
(8) Audience position/ride vehicle position indicators
(9) Others as required by the operation of the show

A.9.3.4.4 Some of the sensors that are currently in use for monitoring these characteristics are as follows:

(1) Ultraviolet flame detector in combination with a listed primary safety control
(2) Infrared flame detector in combination with a listed primary safety control
(3) Flame rod in combination with a listed primary safety control
(4) Thermocouple temperature sensor in combination with a listed primary safety control or as part of a listed automatic valve assembly
(5) Other devices directly sensitive to the characteristics of the means of ignition and acceptable to the authority having jurisdiction

A.9.3.5 The firing of the flame effect is normally achieved through the release of the fuel into ambient air where the mixture is ignited by an ignition device. Normally, this is achieved by the opening of a manual or electrically actuated fuel release valve. Other methods of fuel release are acceptable on the approval of the local authority. Examples of firing methods for flame effects are as follows:

(1) Manual firing by cast member or technician
(2) Firing by a timer and/or programmable logic controller (PLC)
(3) Firing by a PLC with PME

A.9.3.5.3 Certain venues can have areas, both visible to and out of sight of the technical director, in which a person who is present in the area during the firing of the effects might be exposed to the possibility of injury. These areas should be supervised by an intrusion monitor and alarm system during all times when the effects are enabled.

A.9.3.5.4 Certain venues can have areas, both visible to and out of sight of the technical director, where during the enable process one of the following can occur:

(1) Cast members can be present immediately before or after the firing of the effect.
(2) Members of the audience might enter the area during the firing of the effect.
(3) Moving set pieces can affect the safe operation of the effect.

A PME of the flame effect control system should be maintained by a qualified operator with a clear view of the operating area of the effect during the entire process of the enabling, arming, and firing of the effect.

Where the technical director does not have a clear view of the hazard area, additional PME devices should be installed and operated by qualified operators who are in such a position that they have a clear view of the area. Cast members who can be present immediately before the arming and firing of the effect should have additional PME devices that have to be actuated before the flame effect can be fired.

These PME devices should have the following characteristics:

(1) The PME device should consist of a momentary contact push button switch that will close a normally open isolated contact when depressed, thereby sending a confirming signal to show control.
(2) These enable operators should be located in positions such that the technician or cast member can view the effects area and/or confirm that they are safely out of harm's way.
(3) Manual enable operators should be clearly identified as to function. Indicator lights can be provided in the push button or adjacent to the push button to confirm to the operator that the enable signal has been sent to show control.
(4) In the event that any PME signal is not sent or is removed during the arming and firing sequence of an effect, a non-recycling shutdown of that effect or group of effects should occur. The effects can be returned to service only following the removal of the effect enable input and restarting the process. Other flame effects and show elements can continue to operate normally for the remainder of the show.

Repetitive protective operations by human operators are of limited value due to the acclimatization of the operator. When repetitive enabling of an effect is required, appropriate steps should be taken to assure that the operator remains alert for every action.

Although each situation is different and multiple remedies could be required in some situations, steps that can be used to address this concern include the following:

(1) Use two individually monitored buttons, each serving the same enabling function, separated by a distance such that the operator has to be facing the area of safety concern when the buttons are pressed.
(2) Activate the buttons upon an indication in the vicinity of the area of safety concern. For example, rather than illuminating the enable buttons, illuminate an indicator near the flame so that the operator will be encouraged to look in the direction of the flame to determine when to press the enable button.

(3) Vary the timing of the effect to the extent possible within the creative constraints of the show.

A.11.2.1 The following steps are recommended as part of the fire hazards evaluation procedure:

(1) List and describe the following:
    (a) Sources of ignition
    (b) Spread of fire
    (c) Potential duration of fire
    (d) Smoke generation
    (e) Potential collection or drift of flammable vapors and gases
    (f) Exposure of personnel to decomposition products
    (g) The time required for emergency evacuation of the audience
    (h) Extinguishment potential of supplemental standby fire equipment
    (i) The additional fire load from the flame effect
    (j) Existing building fire protection systems
    (k) Other factors specific to the flame effect
(2) Prepare a general description of the fire prevention and fire protection systems that exist and that will be provided. Define the fire hazards that can exist and state the loss-limiting criteria to be used in the design of the flame effect.
(3) Conduct an exposure analysis to determine safe distances of the flame effect from adjacent facilities. Consider the use and effect of noncombustible fire-retardant and heat-resistant materials.
(4) Review and describe the control and operating room areas, if applicable, and the detection and extinguishing systems that will be provided for these areas.

A.11.3 Supplemental fire protection equipment can consist of charged handlines, hand portable extinguishers, wheeled extinguishers, pre-engineered or engineered systems capable of properly extinguishing the flame effect, and any combustible materials within the immediate area. The manufacturer of the equipment should be consulted for assistance on fire extinguishing equipment and agents.

Annex B Design of Flame Effects

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

B.1 Design Plan. The design plan for flame effects should be based on the criteria outlined in B.1.1 through B.1.2.

B.1.1 Location.

B.1.1.1 The design plan for outdoor flame effects should include the following:

(1) Weather (e.g., wind), with safety provisions provided to halt the effect where safe operation of a flame effect can be influenced by hazardous weather conditions
(2) Intrusion (security)
(3) Egress
(4) Clearance to combustibles
(5) Fire protection

B.1.1.2 The design plan for indoor flame effects should include the following:

(1) Ventilation (where used to exhaust the products of combustion of a flame effect), with means provided to prevent fuel flow in the event that the source of ventilation air is interrupted
(2) Clearance to combustibles
(3) Egress
(4) Environment
(5) Fire protection
(6) Life safety provisions
(7) Intrusion (security)

B.1.2 Flame Effect Operator Participation.

B.1.2.1 The design plan for attended effects should include the following:

(1) Control by the operator or performer during start-up, operation, and shutdown
(2) Operator in attendance during effect
(3) Training of operators

B.1.2.2 The design plan for unattended effects should include the following:

(1) Design for unattended operation
(2) Supervision by automatic systems
(3) Audience proximity/audience intrusion prevention
(4) Control type — automatic
    (a) Show events cued by a control system (mechanical or electrical)
    (b) Different levels of automatic operation
    (c) Requirements to be developed for flame effect control systems
(5) Manual control type — supervision of the performance of the device by the operator or technician with the flame effect in open view
(6) Control location
    (a) Local control — a flame effect controlled by an operator who has a clear view of the flame effect area
    (b) Remote control
(7) Fuel supply and fuel additives
    (a) Portable
    (b) Fixed

Annex C Inspection Guidelines

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

C.1 General. The following guidelines are provided as a possible inspection routine that can be used as a model.

C.2 Inspection and Re-Verification of Flame Effects Function. Following issuance of the use permit by the local authority having jurisdiction *(see 5.3.1)* and completing the Approval Requirements *(see Section 5.2)*, the flame effect(s) show action equipment should be subjected to a periodic functional verification and calibration of critical components according to the requirements of a written test plan/procedure as created by the designer of the effects or other responsible individual. A written report and/or completed checklist in a format acceptable to the local jurisdiction should be made a permanent part of the effects documentation.

C.2.1 Temporary Flame Effects Installations. Temporary flame effects installations should be evaluated on a periodic basis by a qualified technician/operator according to the guidelines outlined in C.2.1.1 and C.2.1.2.

C.2.1.1 Daily Inspection and Testing. Any critical deficiencies and/or malfunctions are to be corrected and noted in the show documentation prior to the operation of the effects in the show. Inspection should include the following:

(1) Visual inspection of fuel storage area, which includes verifying that the fuel supply is properly secured, that general housekeeping is according to proper standards, whether there is accumulation of flammable materials, convenient access to critical areas, and the absence of any items not directly related to the storage or management of the fuel supply.
(2) Visual inspection of performance area(s), which includes general housekeeping, accumulation of incidental flammable materials, condition of sets and props, convenience of access, and any other condition relating to the proper operation of the effects.
(3) Visual inspection of fire effects equipment to verify that the components are functional. Significant degradation or damage should be noted and repaired or replaced as necessary.
(4) As part of the daily preset for the show, the effect(s) should be operated according to the procedure established by the designer of the effect to verify the proper operation of the enable and arming as designed. Any discrepancies in the normal operation of the effect should be noted and corrected prior to the operation of the effect during the show.
(5) Verification that all provisions for the emergency shutdown of the effect, including fuel management and fire suppression measures, are present and/or operating normally.
(6) Observation of the operation of the effect during the show to verify that it is functioning according to the expected operating profile.

C.2.1.2 Weekly and Monthly Inspection and Testing. Weekly and monthly inspection and testing should be conducted and noted as dictated by the design and operation of the effects and the duration of the temporary installation.

C.2.2 Permanent Flame Effects Installations. Permanent flame effects installations should be evaluated on a periodic basis by a qualified operator according to the guidelines outlined in C.2.2.1 through C.2.2.4.

C.2.2.1 Daily Inspection and Testing. Any critical deficiencies and/or malfunctions are to be corrected and noted in the show documentation prior to the operation of the effects during the show. Inspection should include the following:

(1) Visual inspection of fuel storage area, which includes verifying that the fuel supply is properly secured, that general housekeeping is according to proper standards, whether there is accumulation of flammable materials, convenient access to critical areas, and the absence of any items not directly related to the storage or management of the fuel supply.
(2) Visual inspection of performance area(s), which includes general housekeeping, accumulation of incidental flammable materials, condition of sets and props, convenience of access, and any other condition relating to the proper operation of the effects.
(3) Visual inspection of fire effects equipment to verify that the components are functional. Significant degradation or damage should be noted and repaired or replaced as necessary.
(4) Verification that all primary limits [lower explosive limit (LEL) sensors, airflow switches, fuel pressure switches, etc.] are conditioned in the proper control profile and that they indicate a proper operating level of the parameter being monitored.
(5) As part of the daily preset for the show, the effect(s) should be operated according to the procedure established by the designer of the effect to verify the proper operation of the enable and arming as designed. Any discrepancies in the normal operation of the effect should be noted and corrected prior to the operation of the effect during the show.
(6) Verification that all provisions for the emergency shutdown of the effect, including fuel management and fire suppression measures, are present and/or operating normally.
(7) Observation of the operation of the effect during the show to verify that it is functioning according to the expected operating profile.

C.2.2.2 Monthly Inspection and Testing. In addition to the recommended tests as stated in C.2.2.1, the following tests and inspections should be performed as required:

(1) Test and calibrate any limit or interlock control device that could be subject to a change in the measured value as a normal part of the operation of the device over a period of time according to the recommendations of the manufacturer.
(2) Perform a leak test of any primary fuel supply shutoff valves according to the recommendations of the manufacturer.
(3) Verify that any intrusion and/or position interlocks are operating properly and the actuation of any such device results in the desired control system response.
(4) Other test sequences as recommended by the effects designer or other cognizant individual.

C.2.2.3 Quarterly Inspection and Testing. In addition to the recommended tests as stated in C.2.2.1 and C.2.2.2, the following tests and inspections should be performed as required:

(1) Calibrate all primary limit or interlock control devices, which could be subject to a change in the measured value as a normal part of the operation of the device over a period of time.
(2) Actuate all primary limit or interlock control devices to confirm proper function, control response, and confirmation of actuation.
(3) Actuate any central fire alarm system to verify that the actuation will result in the emergency stop of the effects control system.
(4) Actuate all show emergency stop operators to confirm their proper function and confirmation of actuation. Furthermore, selected emergency stop operators should be actuated during the operation of the effects to verify the proper emergency shutdown of the effects.
(5) Operate the fuel supply enable control circuit to verify the proper function of the fuel limits and valves.
(6) Enable and arm randomly selected effects to verify the proper operation of the ignition management control circuit, including safe start check, trial for ignition, flame failure response time, and non-recycling operation as necessary. The number of effects to be tested should be a minimum of 3 or 20 percent of the total number of flame effects in the control system. Where the design of the

controls includes multiple zones, at least one effect in each zone should be tested.

(7) Test the PME operator during the operation of the effects to verify that the effects will not enable, arm, and fire without the presence of the PME and that the removal of the PME during the enabling, arming, and firing sequence of the effects will shut down the effects operation as designed.

(8) Operate the effects in the normal show mode to verify that they are enabling, arming, and firing in the expected sequence according to the normal show profile.

(9) Other test sequences as recommended by the effects designer or other cognizant individual.

C.2.2.4 Annual Inspection. The annual inspection of the flame effects will verify the proper function of all effects control components and serve as a certification of the condition and operation of the effects control system for the renewal of the operating permit as issued by the local jurisdiction. The test sequence should include those sequences as stated in C.2.2.1, C.2.2.2, and C.2.2.3, to such an extent that all control systems and components are tested, verified, and functioning properly, and that any other tests as recommended by the effects designer or other cognizant individual are performed.

NFPA® 170

Standard for

Fire Safety and Emergency Symbols

2015 Edition

This edition of NFPA 170, *Standard for Fire Safety and Emergency Symbols*, was prepared by the Technical Committee on Fire Safety and Emergency Symbols. It was issued by the Standards Council on November 11, 2014, with an effective date of December 1, 2014, and supersedes all previous editions.

This edition of NFPA 170 was approved as an American National Standard on December 1, 2014.

Origin and Development of NFPA 170

The 1994 edition of NFPA 170 represented the completion of an effort to combine four previously separate documents that covered fire safety symbols for different purposes. These documents were the following:

NFPA 171, *Public Firesafety Symbols*

NFPA 172, *Fire Protection Symbols for Architectural and Engineering Drawings*

NFPA 174, *Fire Protection Symbols for Risk Analysis Diagrams*

NFPA 178, *Symbols for Fire Fighting Operations*

The Technical Committee on Fire Safety Symbols believed that placing all fire safety symbols in one document made it easier for users of symbols to find the one(s) most appropriate for their application. It also eliminated duplication between these and eventually other NFPA documents.

The first edition of NFPA 170, in 1991, placed these four documents in one document but did not combine them, except for definitions that were in each document.

For the second edition of NFPA 170, in 1994, the Technical Committee on Fire Safety Symbols completely restructured the text into a logical and cohesive arrangement. The duplication of symbols that occurred during the aforementioned consolidation of documents was eliminated. New symbols added included those for *campfire prohibitions*, *smoke barriers*, *illuminated exit signs*, and *belowground tanks*.

For the third (1996) edition of NFPA 170, changes included the following:

(1) Upgrading recommendations on *pre-incident planning* to requirements
(2) Adding new symbols for *pull station*, *area of refuge*, and *cooking prohibition*
(3) Clarifying the symbols for *smoke detectors*, *battery-powered emergency lights*, and *fire service/emergency telephone station*
(4) Recognizing the phaseout of Halon now taking place and the introduction of *clean agents*

The 1999 edition further recognized the introduction of clean agents by adding new symbols for *clean agent* and *water mist systems*. A new appendix (Appendix C) was added to include symbols that can be used for life safety planning.

The 2002 edition was reformatted to conform to the *Manual of Style for NFPA Technical Committee Documents*. Symbols for fire alarm system components were added for consistency with *NFPA 72®*, *National Fire Alarm Code®*.

In 2004, the scope of the committee was expanded to include emergency symbols to allow emergency mapping symbols in a new Chapter 8.

The 2006 edition of NFPA 170 included the refinement of exit symbology for better recognition of exit, arrow, and flame symbols that are consistent with international standards.

NFPA and National Fire Protection Association are registered trademarks of the National Fire Protection Association, Quincy, Massachusetts 02169.

A new Chapter 8, Symbology for Emergency Management Mapping, was added to assist the user in the preparation for, prevention of, protection against, response to, and recovery from threats to the nation's population centers and critical infrastructure from terrorist, criminal, accidental, or natural origin.

The symbols in Chapter 8 were the result of efforts by the Federal Geographic Data Committee — Homeland Security Working Group (http://www.fgdc.gov/fgdc/homeland/index.html). The symbols were included in the 2006 edition so that they can be processed through an accredited standards-writing organization and made available to the public.

The 2009 edition of NFPA 170 included a new chapter (Chapter 9) that provided guidance on the development of emergency evacuation diagrams and plans.

The 2012 edition of NFPA 170 included a new Chapter 7 and a new Chapter 8, previously all encompassed within the old Chapter 6. This affected symbol detail for various device symbols such as fire alarm devices, fire sprinkler devices, electronic fire and smoke detection, and so forth. This action better organized existing symbols within the standard for the user.

The 2015 edition has revised several symbols for consistency and clarity. The "wisp of smoke" has been replaced by an "S" to simplify the symbol when viewed on plans. Many tables have been reorganized for clarity and ease of use as well.

This list represents the membership at the time the Committee was balloted on the final text of this edition. Since that time, changes in the membership may have occurred. A key to classifications is found at the back of the document.

NOTE: Membership on a committee shall not in and of itself constitute an endorsement of the Association or any document developed by the committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on fire safety and emergency symbols including those for building design plans, investigation diagrams, maps, and for public fire safety and emergency. It shall coordinate its work with NFPA technical committees and other groups dealing with subjects to which fire safety symbols apply.

NFPA 170

Standard for

Fire Safety and Emergency Symbols

2015 Edition

IMPORTANT NOTE: This NFPA document is made available for use subject to important notices and legal disclaimers. These notices and disclaimers appear in all publications containing this document and may be found under the heading "Important Notices and Disclaimers Concerning NFPA Standards." They can also be obtained on request from NFPA or viewed at www.nfpa.org/disclaimers.

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates that explanatory material on the paragraph can be found in Annex A.

A reference in brackets [ ] following a section or paragraph indicates material that has been extracted from another NFPA document. As an aid to the user, the complete title and edition of the source documents for extracts in mandatory sections of the document are given in Chapter 2 and those for extracts in informational sections are given in Annex D. Extracted text may be edited for consistency and style and may include the revision of internal paragraph references and other references as appropriate. Requests for interpretations or revisions of extracted text shall be sent to the technical committee responsible for the source document.

Information on referenced publications can be found in Chapter 2 and Annex D.

Chapter 1 Administration

1.1 Scope. This standard presents symbols used for fire safety, emergency, and associated hazards.

1.2 Purpose. The purpose of this standard is to standardize the symbols used in representing fire safety, emergency, and associated hazards.

1.3 Retroactivity. The provisions of this standard reflect a consensus of what is necessary to provide an acceptable degree of protection from the hazards addressed in this standard at the time the standard was issued.

1.3.1 Unless otherwise specified, the provisions of this standard shall not apply to facilities, equipment, structures, or installations that existed or were approved for construction or installation prior to the effective date of the standard. Where specified, the provisions of this standard shall be retroactive.

1.3.2 In those cases where the authority having jurisdiction determines that the existing situation presents an unacceptable degree of risk, the authority having jurisdiction shall be permitted to apply retroactively any portions of this standard deemed appropriate.

1.3.3 The retroactive requirements of this standard shall be permitted to be modified if their application clearly would be impractical in the judgment of the authority having jurisdiction, and only where it is clearly evident that a reasonable degree of safety is provided.

1.4 Equivalency. Nothing in this standard is intended to prevent the use of systems, methods, or devices of equivalent or superior quality, strength, fire resistance, effectiveness, durability, and safety over those prescribed by this standard.

1.4.1 Technical documentation shall be submitted to the authority having jurisdiction to demonstrate equivalency.

1.4.2 The system, method, or device shall be approved for the intended purpose by the authority having jurisdiction.

1.5 Units. Metric units of measurement used in this standard shall be in accordance with the International System of Units (SI). One unit (liter), outside of but recognized by SI, is commonly used in international fire protection. For conversion factors, see Table 1.5.

Table 1.5 Metric Conversion Factors

Name of Unit	Unit Symbol	Conversion Factor
Liter	L	1 gal = 3.785 L
Cubic decimeter	dm^3	1 gal = 3.785 dm^3
Pascal	Pa	1 psi = 6894.757 Pa
Meter	m	1 ft = 0.3048 m
Millimeter	mm	1 in. = 25.4 mm

Chapter 2 Referenced Publications

2.1 General. The documents or portions thereof listed in this chapter are referenced within this standard and shall be considered part of the requirements of this document.

2.2 NFPA Publications. National Fire Protection Association, 1 Batterymarch Park, Quincy, MA 02169-7471.

NFPA *101*®, *Life Safety Code*®, 2015 edition.

NFPA 704, *Standard System for the Identification of the Hazards of Materials for Emergency Response,* 2012 edition.

2.3 Other Publications.

2.3.1 ANSI Publications. American National Standards Institute, Inc., 25 West 43rd Street, 4th Floor, New York, NY 10036.

ANSI A117.1, *Accessible and Usable Buildings and Facilities,* 2009.

ANSI Z535.1, *Safety Color Code,* 2011.

2.3.2 NECA Publications. National Electrical Contractors Association, 3 Bethesda Metro Center, Suite 1100, Bethesda, MD 20814.

NECA 100, *Symbols for Electrical Construction Drawings*, 2006.

2.3.3 Other Publications.

Merriam-Webster's Collegiate Dictionary, 11th edition, Merriam-Webster, Inc., Springfield, MA, 2003.

2.4 References for Extracts in Mandatory Sections.

NFPA 10, *Standard for Portable Fire Extinguishers,* 2013 edition.

NFPA *101*®, *Life Safety Code*®, 2015 edition.

Chapter 3 Definitions

3.1 General. The definitions contained in this chapter shall apply to the terms used in this standard. Where terms are not defined in this chapter or within another chapter, they shall be defined using their ordinarily accepted meanings within the context in which they are used. *Merriam-Webster's Collegiate Dictionary*, 11th edition, shall be the source for the ordinarily accepted meaning.

3.2 NFPA Official Definitions.

3.2.1 Approved. Acceptable to the authority having jurisdiction.

3.2.2* Authority Having Jurisdiction (AHJ). An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

3.2.3 Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

3.2.4* Listed. Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

3.2.5 Shall. Indicates a mandatory requirement.

3.2.6 Should. Indicates a recommendation or that which is advised but not required.

3.2.7 Standard. An NFPA Standard, the main text of which contains only mandatory provisions using the word "shall" to indicate requirements and that is in a form generally suitable for mandatory reference by another standard or code or for adoption into law. Nonmandatory provisions are not to be considered a part of the requirements of a standard and shall be located in an appendix, annex, footnote, informational note, or other means as permitted in the NFPA Manuals of Style. When used in a generic sense, such as in the phrase "standards development process" or "standards development activities," the term "standards" includes all NFPA Standards, including Codes, Standards, Recommended Practices, and Guides.

3.3 General Definitions.

3.3.1 Photoluminescent. Having the ability to store incident electromagnetic radiation typically from ambient light sources, and release it in the form of visible light. [***101***, 2015]

3.3.2 Pre-Incident Planning. A written document resulting from the gathering of general and detailed information/data to be used by public emergency response agencies and private industry for determining the response to reasonable anticipated emergency incidents at a specific facility.

3.3.3* Referent. An object or concept (message) represented by a symbol.

3.3.4 Self-luminous (Emergency Symbols). A type of sign that is self-energized used for an emergency symbol with respect to luminosity and requires no external power source, or photoluminescent materials having the ability to store incident electromagnetic radiation typically from ambient light sources, and release it in the form of visible light.

3.3.5* Supplementary Indicators. Figures, numbers, subscripts, or letter abbreviations used to enhance the effectiveness of symbols.

3.3.6* Symbol. A graphic representation of a referent.

Chapter 4 Symbols for General Use

4.1 Introduction.

4.1.1 This chapter presents general referents and symbols for fire prevention and visual alerting that shall be used for fire and related life safety emergencies.

4.1.2 Purpose.

4.1.2.1 This chapter shall provide uniform fire safety symbols to improve communication wherever signs and symbols are employed to provide fire safety information.

4.1.2.2 This chapter provides uniformity in the selection of symbols that shall be designed to assist in locating exits, fire safety alerting equipment, and safe areas.

4.1.2.3* The fundamental imagery for symbols, as well as their background color and shape, shall be designated in this chapter.

4.1.3* Symbol Presentation.

4.1.3.1 The orientation for prohibition symbols shall not be altered from that shown in this chapter.

4.1.3.2 The symbol background shape shall be as specified in Table 4.2.

4.1.3.2.1* For prohibition symbols, a circle and diagonal slash (at 45 degrees from upper left to lower right) shall be used.

4.1.3.3 Symbol Color. The symbol color shall meet the requirements of ANSI Z535.1, *Safety Color Code.*

4.1.3.4* Symbols shall be permitted to be used in combination with other symbols, either vertically or horizontally, on the same sign or on separate signs adjacent to each other.

4.2* Symbols for General Use. The symbols for general use shall be as given in Table 4.2.

4.3 Class of Fire Symbols. The symbols for class of fire shall be as given in Figure 4.3(a) and Figure 4.3(b).

Table 4.2 Symbols for General Use

Symbol	Characteristics	Application	Example
Emergency Exit 	Square field Background green Door opening white Image in green	The identification and location of an emergency exit	The location of exit for use in a fire emergency
Emergency Exit Use of Arrows — Rectangular Field 	Painted version: Background color white Arrows red or black Backlit version: Doorway, arrows, and lettering in green or red	The identification and location of a route to an emergency exit	Progress to the right
	Painted version: Background color white Arrows red or black Backlit version: Doorway, arrows, and lettering in green or red	The identification and location of a route to an emergency exit	Progress up and to the right
	Painted version: Background color white Arrows red or black Backlit version: Doorway, arrows, and lettering in green or red	The identification and location of a route to an emergency exit	Progress down and to the right
	Painted version: Background color white Arrows red or black Backlit version: Doorway, arrows, and lettering in green or red	The identification and location of a route to an emergency exit	Progress forward
	Painted version: Background color white Arrows red or black Backlit version: Doorway, arrows, and lettering in green or red	The identification and location of a route to an emergency exit	Progress down
	Painted version: Background color white Arrows red or black Backlit version: Doorway, arrows, and lettering in green or red	The identification and location of a route to an emergency exit	Progress to the left

(continues)

Table 4.2 *Continued*

Symbol	Characteristics	Application	Example
	Painted version: Background color white Arrows red or black Backlit version: Doorway, arrows, and lettering in green or red	The identification and location of a route to an emergency exit	Progress up and to the left
	Painted version: Background color white Arrows red or black Backlit version: Doorway, arrows, and lettering in green or red	The identification and location of a route to an emergency exit	Progress down and to the left
Emergency Exit Route (Combination of Two Symbols)    	Square field Background green Door opening white Image in green For arrows: Square field Green arrow on white background or white arrow on green background	The identification and location of a route to be used in an emergency	The direction to a fire exit
Accessible Emergency Exit (Combination of Two Symbols)  	Square field Background green Door opening white Image in green International symbol of accessibility per ANSI A117.1, *Accessible and Usable Buildings and Facilities*	The identification of a route that leads to an emergency exit that is accessible to disabled users, as specified by ANSI A117.1, *Accessible and Usable Buildings and Facilities*	The location of a route toward a fire exit that is accessible to disabled users

Table 4.2 *Continued*

Symbol	Characteristics	Application	Example
Accessible Emergency Exit Route (Combination of Three Symbols) 	Square field Background green Door opening white Image in green	The identification of a route that leads to an emergency exit that is accessible to disabled users	The location of the route toward a fire exit that is accessible to disabled users
	International symbol of accessibility per ANSI A117.1, *Accessible and Usable Buildings and Facilities*		
	For arrows: Square field Green arrow on white background or white arrow on green background		
Not an Exit 	Circular field Red prohibition symbol Background white Door frame green Door opening white Image in black	The identification of doors that do NOT lead to an exit	The location of an interior door such as one leading to a closet, an interior courtyard, or a basement
Use Stairs in Case of Fire 	Square field Red flame Black figure White background	An instruction to the user to use stairs (downward egress) in case of fire	The identification that stairs are to be used in case of fire
Use Stairs in Case of Fire 	Square field Red flame Black figure White background	An instruction to the user to use stairs (upward egress) in case of fire	The identification that stairs are to be used in case of fire

(continues)

Table 4.2 ***Continued***

Symbol	Characteristics	Application	Example
Do Not Use Elevator in Case of Fire 	Rectangular field Red flame Black figures White background Red circle and slash	An instruction not to use elevators in case of fire	Posted near elevator call button
No Open Flame — Flame 	Circular field Red circle and slash Black image White background	The identification of areas in which open flame is prohibited	The identification of areas, such as combustible storage areas, gas stations, and hazardous areas
No Open Flame — Lighted Match 	Circular field Red circle and slash Black image White background	An instruction not to use lighted matches	Where posted, the use of matches is prohibited
No Smoking 	Circular field Red circle and slash Black image White background	The identification of areas in which smoking is prohibited	The identification of areas, such as those for flammable liquid storage, where smoking could lead to fire or explosion
No Campfires 	Circular field Red circle and slash Black image White background	The identification of areas where campfires are not permitted	The identification of areas, such as municipal parks, where campfires are not permitted

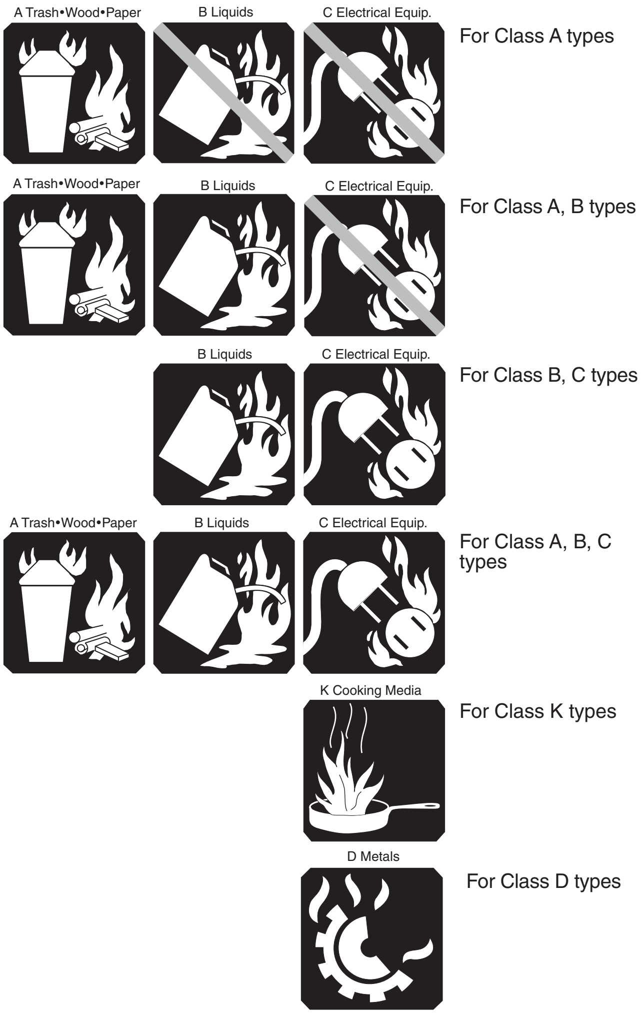
Table 4.2 *Continued*

Symbol	Characteristics	Application	Example
Manual Station — Pull Station/Fire Alarm Box 	Rectangular field Red background White flame White hand White box White horn	An instruction to actuate an alarm-initiating device in a fire emergency	Posted above a manually activated initiating device
No Cooking 	Square field White background Red flame Black pot and steam Red circle and slash	An instruction not to cook food in an area	Posted inside a guest room in a hotel or a student room in a college dormitory
Area of Refuge 	Square field White background Red flame	The identification of an area of refuge	A designated area of refuge to be used in a fire emergency
No Hanger 	Red circle and slash Black image	To prohibit hanging clothes or other items from sprinklers	Where posted
Automated External Defibrillator (AED) 	Square field White background Red heart White bolt through the heart Black lettering	To identify the location of AEDs	Posted in airports and other places of assembly

(continues)

Table 4.2 *Continued*

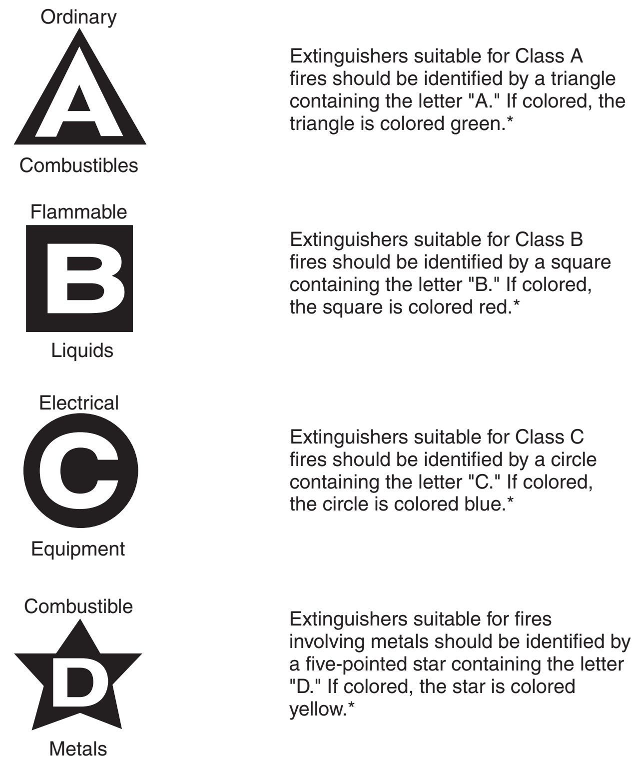
Symbol	Characteristics	Application	Example
Fire Extinguisher 	Square field Red background White symbol	For everyday use in workplaces and public areas; supplementary text sign can be used to increase comprehension	Fire safety signage, manuals, and notices
Fire Hose or Standpipe 	Square field Red background White symbol	For everyday use in workplaces and public areas; supplementary text sign can be used to increase comprehension	Fire safety signage, manuals, and notices



Note: Recommended colors, per PMS (Pantone Matching System) include the following:

BLUE — 299
RED — Warm Red

FIGURE 4.3(a) Recommended Marking System. [10:Figure B.1.1]



* Recommended colors, per PMS (Pantone Matching System) include the following:

GREEN — Basic Green
RED — 192 Red
BLUE — Process Blue
YELLOW — Basic Yellow

FIGURE 4.3(b) Letter-Shaped Symbol Markings. [10:Figure B.2.2]

Chapter 5 Symbols for Use by the Fire Service

5.1 Introduction.

5.1.1* This chapter presents standard referents and symbols that shall be used for visually alerting fire fighters and other emergency responders during fire and related emergencies.

5.1.2* Fundamental shapes of symbols, as well as the background color and shape, shall be as designated in this chapter.

5.1.3* Symbol Presentation.

5.1.3.1* Symbol Shapes. The shape of symbols shall be as illustrated in Section 5.2.

5.1.3.2 Symbol Background.

5.1.3.2.1 The symbol background shall be as specified in Table 5.2.

5.1.3.2.2 The symbol background color shall be red, white, or blue as designated and shall meet the requirements of ANSI Z535.1, *Safety Color Code,* for safety red, white, or blue.

5.1.3.3 Symbol Color. The symbol color shall be safety white or blue and shall meet the requirements of ANSI Z535.1, *Safety Color Code,* for safety white or blue.

5.1.3.4 Symbol Orientation. Symbol orientation shall not be altered from that shown in this chapter.

5.2* Symbols for Use by the Fire Service. The symbols for use by the fire service shall be as given in Table 5.2.

Table 5.2 Symbols for Use by the Fire Service

Symbol	Characteristics	Application	Examples
Fire Department Automatic Sprinkler Connection — Siamese 	Square field Red background White symbol	The identification and location of a fire department automatic sprinkler connection	The location of a siamese automatic sprinkler connections on buildings The location of siamese freestanding automatic sprinkler connections
Fire Department Automatic Sprinkler Connection — Single 	Square field Red background White symbol	The identification and location of a fire department automatic sprinkler connection	The location of a single automatic sprinkler connection on buildings The location of a single freestanding automatic sprinkler connection
Fire Department Standpipe Connection 	Square field Red background White symbol	The identification and location of a fire department standpipe connection	The location of standpipe connections on buildings and structures The location of freestanding standpipe connections
Fire Department Combined Automatic Sprinkler/Standpipe Connection 	Square field Red background White symbol	The identification and location of a fire department combined automatic sprinkler/standpipe connection	The location of combined sprinkler/standpipe connections on buildings The location of freestanding combined sprinkler/standpipe connections

Table 5.2 *Continued*

Symbol	Characteristics	Application	Examples
Fire Hydrant (All Types) 	Square field Red background White symbol	The identification and location of a fire hydrant	The location of fire hydrants, wall hydrants, underground hydrants, or other fire-fighting water supplies
Automatic Sprinkler Control Valve 	Square field Red background White symbol	The identification and location of an automatic sprinkler control valve	The location of control valves for automatic sprinkler systems On doors of rooms containing control valves
Electric Panel or Electric Shutoff 	Square field Blue background White symbol	The identification and location of an electrical panel or other electric shutoff device	The location of electric panels or other electric control devices that can be located in basements or mechanical rooms
Gas Shutoff Valve 	Square field Red background White symbol Red letter G	The location of a gas shutoff valve	The location of gas shutoff valves On doors of rooms containing gas shutoff valves
Fire-Fighting Hose or Standpipe Outlet 	Square field Red background White symbol	The location of a fire-fighting hose or a standpipe outlet	The location of interior fire-fighting hose stations and standpipe outlets in buildings and structures The location on bridges or elevated highways

(continues)

Table 5.2 *Continued*

Symbol	Characteristics	Application	Examples
Fire Extinguisher 	Square field Red background White symbol	The location of a fire extinguisher	The location of fire extinguishers in buildings and exterior locations
Directional Arrow 	Square field Background green to correspond to accompanying sign White symbol	Direction to the location of fire-fighting equipment or utility; always used in conjunction with, and adjacent to, another symbol indicating the particular equipment or utility	
Diagonal Directional Arrow 	Square field Background green to correspond to accompanying sign White symbol	Direction to the location of fire-fighting equipment or utility; always used in conjunction with, and adjacent to, another symbol indicating the particular equipment or utility	
Child Care Center 	Square field Blue infant and hands White background	The identification and location of child care centers	On the door opening into child care centers At a fire department command or access point indicating presence and location of child care centers
Emergency Telephone 	Square field Red background White phone	The identification and location of fire service or emergency telephone system	
No Fire Fighting 	Red prohibition symbol Circular field White background Black truck within black octagonal outline	To be posted on, near, or on the approach to buildings where fire fighting is not to occur	Explosives bunkers, frangible buildings, or contaminated buildings

Table 5.2 *Continued*

Symbol	Characteristics	Application	Examples
Self-Contained Breathing Apparatus (SCBA) 	Rectangular field White symbol Green background	To indicate the location of SCBA, breathing air connections, or refill location	For SCBA fill locations in high-rise buildings

Chapter 6 Symbols for Use in Architectural and Engineering Drawings and Insurance Diagrams

6.1* Introduction.

6.1.1 This chapter presents symbols that shall be used in drawings and diagrams.

6.1.2* Symbol Presentation.

6.1.2.1* Symbol Shapes. The shape of symbols shall be as illustrated in Sections 6.2 through 7.9.

6.1.2.2 Screened Lines. Screened lines in the chapter shall not be considered part of the symbol but shall be used to represent the piping, wiring, or mounting surface associated with the symbol.

6.1.2.3 Symbol Scale. All scales for symbols on any one drawing shall be the same relative size.

6.1.2.4* Symbol Orientation. Symbols shall be oriented to the walls, piping, electrical lines, and so forth, to which they are attached.

6.2 Symbols for Site Features.

6.2.1 Buildings.

6.2.1.1 The exterior walls of buildings shall be outlined in single thickness lines if other than fire rated and double thickness lines if fire rated.

6.2.1.2* The perimeter of canopies, loading docks, and other open-walled structures shall be shown by broken lines.

6.2.2 Railroad Tracks. Railroad tracks shall be shown by a single line with cross dashes, as shown in Figure 6.2.2.

FIGURE 6.2.2 Symbol for Railroad Tracks.

6.2.3* Streets. Streets shall be shown.

6.2.4* Bodies of Water. Rivers, lakes, and so forth, shall be outlined.

6.2.5 Fences.

6.2.5.1 Fences shall be shown by lines with x's evenly spaced.

6.2.5.2* Gates shall be shown.

6.2.6 Property Lines. The notation given in Figure 6.2.6 shall indicate property lines.

FIGURE 6.2.6 Notation Indicating Property Lines.

6.2.7 Fire Department Access. The symbol for fire department access shall be as shown in Figure 6.2.7.

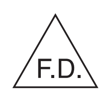


FIGURE 6.2.7 Symbol for Fire Department Access.

6.2.8 Other Site Features. For other fire protection site features, Section 7.2 shall be viewed.

6.3 Symbols for Building Construction.

6.3.1* Types of Building Construction. Types of construction shall be shown narratively.

6.3.2* Height. Height shall be shown to indicate number of stories above ground, number of stories below ground, and height from grade to eaves.

6.3.3* Symbols for Walls and Parapets. Symbols for walls and parapets shall be as given in Table 6.3.3.

Table 6.3.3 Symbols for Walls and Parapets

Symbol	Description
	Wall — basic shape
	Smoke barrier wall
	½-hour fire barrier wall
	½-hour fire/smoke barrier wall
	¾-hour fire barrier wall
	¾-hour fire/smoke barrier wall
	1-hour fire barrier wall
	1-hour fire/smoke barrier wall
	2-hour fire barrier wall
	2-hour fire wall
	2-hour fire/smoke barrier wall
	3-hour fire barrier wall
	3-hour fire wall
	3-hour fire/smoke barrier wall
	4-hour fire barrier wall

Table 6.3.3 *Continued*

Symbol	Description
	4-hour fire wall
	4-hour fire/smoke barrier wall
	Parapet — One cross for each 150 mm (6 in.) parapet that extends above roof (shown is plan view of symbol).

6.3.4 Symbols for Floor Openings, Wall Openings, Roof Openings, and Their Protection. Symbols for floor openings, wall openings, roof openings, and their protection shall be as given in Table 6.3.4.

Table 6.3.4 Symbols for Floor Openings, Wall Openings, Roof Openings, and Their Protection and Life Safety Plans

Symbol	Description	Comments
	Opening in wall	
	Rated fire door in wall (less than 3 hours)	
	Fire door in wall (3-hour rated)	
	Elevator in combustible shaft	
	Elevator in noncombustible shaft	
	Open hoistway	
	Escalator	
	Stairs in combustible shaft	
	Stairs in fire-rated shaft	

Table 6.3.4 *Continued*

Symbol	Description	Comments
	Stairs in open shaft	
	Skylight	
E: _ _	Egress component identifier	Specify egress component: EX# = Exit number HE = Horizontal exit EP = Exit passageway CP = Common path of travel PD = Public discharge RD = Room door ES = Escape
< _ _ >	Egress component capacity	Specify allowable number of persons through egress component (e.g., < 25 >)
<< _ _ >>	Governing component capacity	Specify maximum capacity of the egress path
_ _ > _ _	Travel distance	Left side: Distance to egress component Right side: Egress component identifier
	Occupancy capacity	Top: Specify capacity Middle: Specify area [square feet (square meters)] Bottom: Specify occupant load factor

Table 6.3.4 *Continued*

Symbol	Description	Comments
	Fire door	
	Non-rated fire door	
	Non-rated smoke-resistant fire door	
	20-minute fire-rated fire door	
	20-minute fire-rated, smoke-resistant fire door	
	½-hour fire-rated fire door	
	½-hour fire-rated, smoke-resistant fire door	
	¾-hour fire-rated fire door	
	¾-hour fire-rated, smoke-resistant fire door	
	1-hour fire-rated fire door	

(continues)

Table 6.3.4 *Continued*

Symbol	Description	Comments
	1-hour fire-rated, smoke-resistant fire door	
	1½-hour fire-rated fire door	
	1½-hour fire-rated, smoke-resistant fire door	
	2-hour fire-rated fire door	
	2-hour fire-rated, smoke-resistant fire door	
	3-hour fire-rated fire door	
	3-hour fire-rated, smoke-resistant fire door	
	Exit	Wide, black, solid line
	Exit access	Wide, black, dashed line
	Exit discharge	Wide, black, short, dashed line

6.3.5* Special Symbols for Cross-Sections. The symbols shown in Table 6.3.5 shall be used to indicate features of cross-sections. It is recognized that descriptive notes often are required.

Table 6.3.5 Special Symbols for Cross-Sections

Symbol	Description	Comments
	Fire-resistive floor or roof	
	Wood-joisted floor or roof	
(Steel deck on steel joists)	Other floors or roofs	Note construction
	Floor/ceiling or roof/ceiling assembly	Details indicated, as necessary
	Floor on ground	
	Truss roof	Note construction

6.3.6 Miscellaneous Features. A number of features related to fire protection that do not fall under 6.3.1 through 6.3.5 shall be as given in Table 6.3.6.

Table 6.3.6 Miscellaneous Features

Symbol	Description	Comments
	Boiler	
	Chimney	Describe height and construction
	Fire escape	
	Horizontal aboveground tank	Indicate type, dimensions, construction, capacity, pressurization, and content
	Vertical aboveground tank	Indicate type, dimensions, construction, capacity, pressurization, and content
	Belowground tank	Indicate type, dimensions, construction, capacity, pressurization, and content
	Class I, Division 1 or 0	Hatch patterns for electrically classified locations
	Class I, Division 1 or Zone 1	Hatch patterns for electrically classified locations
	Class I, Division 2 or Zone 2	Hatch patterns for electrically classified locations
	Designates the location of automated external defibrillators (AEDs) on plans	

Chapter 7 Symbols for Use in Water Supply, Extinguishing, and Sprinkler System Drawings and Insurance Diagrams

7.1* Introduction.

7.1.1 This chapter presents symbols that shall be used in drawings and diagrams.

7.1.2* Symbol Presentation.

7.1.2.1* Symbol Shapes. The shape of symbols shall be as illustrated in Sections 7.2 through 7.7.

7.1.2.2 Screened Lines. Screened lines in the chapter shall not be considered part of the symbol but shall be used to represent the piping, wiring, or mounting surface associated with the symbol.

7.1.2.3 Symbol Scale. All scales for symbols on any one drawing shall be the same relative size.

7.1.2.4* Symbol Orientation. Symbols shall be oriented to the walls, piping, electrical lines, and so forth, to which they are attached.

7.2* Water Supply and Distribution Symbols. Water supply and distribution symbols shall be as given in Table 7.2.

Table 7.2 Water Supply and Distribution Symbols

Symbol	Description	Comments
	Public water main	Indicate pipe size and material
	Private water main	Indicate pipe size and material
	Water main under building	Indicate pipe size and material
	Suction pipe	Indicate pipe size and material
	Thrust block	
	Riser	
	Pipe elbow up or down	Height on either side indicated by pipe height tags
	Pipe tee up or down	Height of crossed pipes indicated by pipe height tags
	Valves (general)	Basic shape; indicate valve size
	Valve in pit	Indicate valve size
	Post-indicator valve	Indicate valve size
	Key-operated valve	Indicate valve size
	OS&Y valve (outside screw and yoke, rising stem)	Indicate valve size
	Indicating butterfly valve	Indicate valve size

Table 7.2 ***Continued***

Symbol	Description	Comments
	Nonindicating valve (nonrising-stem valve)	Indicate valve size
	Check valve	Basic shape; indicate valve size, direction of flow
	Backflow preventer — double check type	Also referred to as a double check valve assembly
	Backflow preventer — reduced pressure zone (RPZ) type	
	Pressure-regulating valve	
	Pressure relief valve	
	Float valve	
	Meter	Indicate type
	Private hydrant, one hose outlet	Indicate size, type of thread, or connection
	Public hydrant, two hose outlets	Indicate size, type of thread, or connection
	Public hydrant, two hose outlets and pumper connection	Indicate size, type of thread, or connection

(continues)

Table 7.2 ***Continued***

Symbol	Description	Comments
	Wall hydrant, two hose outlets	Indicate size, type of thread, or connection
	Private housed hydrant, two hose outlets	Indicate size, type of thread, or connection
	Siamese fire department connection	Specify type, size, and angle
	Freestanding siamese fire department connection	Sidewalk or pit type; specify size
	Single fire department connection	Specify type, size, thread, and angle
	Fire pump with driver	Specify driver type and rated capacity
	Freestanding test header	Freestanding; specify number and sizes of outlets
	Wall-mounted test header	Wall; specify number and sizes of outlets
	Screen/strainer	

7.3 Reserved.

7.4 Symbols Related to Means of Egress. Symbols related to means of egress shall be as given in Table 7.4.

Table 7.4 Symbols Related to Means of Egress

Symbol	Description	Comments
	Emergency light, battery-powered	Number of lamps on unit to be indicated; indicate whether light head(s) [lamp(s)] is remote from battery
	Illuminated exit sign, single face	Indicate direction of flow for the face
	Illuminated exit sign, double face	Indicate direction of flow for each face
	Combined battery-powered emergency light and illuminated exit sign	Number of lamps on unit to be indicated; indicate whether light head(s) [lamp(s)] is remote from battery; indicate direction of flow for the face
	Exit lighting	Exit lighting fixture, arrows, and exit face as indicated on drawings (mounting heights to be determined by job specifications) — from NECA 100, symbol 2.005
	Luminaire providing emergency illumination (filled in)	From NECA 100, symbol 2.300
	Directional sounder — exit marking audible appliance, wall mounted	Applied from NECA 100, symbol 9.109
	Directional sounder — exit marking audible appliance, ceiling mounted	Applied from NECA 100, symbol 9.110
	Directional exit indicating strip lighting appliance	Applied from NECA 100, symbol 2.002

7.5 Indicating Appliances. Symbols for indicating appliances shall be as given in Table 7.5.

Table 7.5 Symbols for Indicating Appliances

Symbol	Description	Comments
	Water motor alarm (water motor gong)	Shield optional

7.6* Symbols for Fire Extinguishing Systems.

7.6.1 Various Types of Fire Extinguishing Systems.

7.6.1.1 Water-Based Systems. Symbols for water-based systems shall be as given in Table 7.6.1.1.

Table 7.6.1.1 Symbols for Water-Based Systems

Symbol	Description
	Wet charged system — automatically actuated
	Wet charged system — manually actuated
	Dry system — automatically actuated
	Dry system — manually actuated
	Foam system — automatically actuated
	Foam system — manually actuated
	Water mist extinguishing system — automatically actuated
	Water mist extinguishing system — manually actuated

7.6.1.2 Dry Chemical Systems. Symbols for dry chemical systems shall be as given in Table 7.6.1.2.

Table 7.6.1.2 Symbols for Dry Chemical Systems

Symbol	Description
	For liquid, gas, and electrical fires — automatically actuated
	For liquid, gas, and electrical fires — manually actuated
	For fires of all types (except metals) — automatically actuated
	For fires of all types (except metals) — manually actuated

7.6.1.3 Systems Utilizing a Gaseous Medium. Symbols for systems utilizing a gaseous medium shall be as given in Table 7.6.1.3.

Table 7.6.1.3 Symbols for Systems Utilizing a Gaseous Medium

Symbol	Description
	Carbon dioxide system — automatically actuated
	Carbon dioxide system — manually actuated
	Halon system or clean agent extinguishing system — automatically actuated
	Halon system or clean agent extinguishing system — manually actuated

7.6.1.4 Supplementary Symbols. Supplementary symbols shall be as given in Table 7.6.1.4.

Table 7.6.1.4 Supplementary Symbols

Symbol	Description
	Fully sprinklered space
	Partially sprinklered space
	Nonsprinklered space
	Water spray system

7.6.2* Symbols for Fire Sprinklers. Symbols for fire sprinklers shall be as given in Table 7.6.2.

Table 7.6.2 Symbols for Fire Sprinklers

Symbol	Description	Comments
	Upright sprinkler	
	Pendent sprinkler	Note “DP” on drawing and/or in specifications where dry pendent sprinklers are employed
	Upright sprinkler; on sprig	
	Upright sprinkler on top of riser nipple	
	Upright sprinkler on top of riser nipple with sprig	
	Pendent sprinkler; on drop nipple	Note “DP” on drawing and/or in specifications where dry pendent sprinklers are employed
	Sprinkler, with guard	Upright sprinkler head shown
	Sidewall sprinkler	
	Outside sprinkler	Specify type, orifice size; for example, open sprinkler (window or cornice)
	Open sprinkler on branch line	
	Open sprinkler on branch line with sprig	
	Water spray nozzle	
	Window sprinklers	

7.6.3* Symbols for Piping, Valves, Control Devices, and Hangers. Symbols for piping, valves, control devices, and hangers shall be as given in Table 7.6.3.

Table 7.6.3 Symbols for Piping, Valves, Control Devices, and Hangers

Symbol	Description	Comments
	Sprinkler piping and branch line	Indicate pipe size
	Pipe trace heater	See NECA 100, symbol 5.106
	Mechanical coupling	
	Pipe hanger	Diagonal stroke imposed on the pipe that the hanger supports
	Lateral brace	
	Longitudinal brace	
	Four-way brace	Only used to brace risers
	Angle valve (angle hose valve)	Indicate size, type, and other required data
	Check valve (general)	
	Alarm check valve	Specify size, direction of flow
	Dry pipe valve	Specify size
	Dry pipe valve with quick opening device (accelerator or exhauster)	Specify size and type
	Deluge valve	Specify size and type
	Preaction valve	Specify size and type

7.7 Symbols for Portable Fire Extinguishers. Symbols for portable fire extinguishers shall be as given in Table 7.7.

Table 7.7 Symbols for Portable Fire Extinguishers

Symbol	Description	Comments
	Portable fire extinguisher	Basic shape
	Water extinguisher	
	Foam extinguisher	
	Dry chemical extinguisher for liquid, gas, or electrical fires	BC type
	Dry chemical extinguisher for fires of all types (except metals)	ABC type
	CO_2 extinguisher	
	Halon or clean agent extinguisher	
	Extinguisher for metal fires	

7.8 Symbols for Fire-Fighting Equipment. Symbols for fire-fighting equipment shall be as given in Table 7.8.

Table 7.8 Symbols for Fire-Fighting Equipment

Symbol	Description	Comments
	Fire-fighting equipment	Basic shape
	CO_2 reel station	
	Dry chemical reel station	
	Fire hose valve connection	Specify thread size
	Foam reel station	
	Hose station, dry standpipe	
	Hose station, wet standpipe	
	Monitor nozzle, dry	Specify orifice size
	Monitor nozzle, charged	Specify orifice size

7.9* Miscellaneous Symbols. Miscellaneous symbols shall be as given in Table 7.9.

Table 7.9 Miscellaneous Symbols

Symbol	Description	Comments
	Agent storage container	Specify type of agent and mounting
	Agent storage container — foam	
	Agent storage container — Halon	

Table 7.9 *Continued*

Symbol	Description	Comments
	Agent storage container — carbon dioxide	
	Agent storage container — clean agent	
	Agent storage container — dry chemical	
	Agent storage container — water mist	
	Agent storage container — wet chemical	
	Special spray nozzle	Specify type, orifice, size, other required data (shown here on pipe)
	Fusible link	Specify degrees
	Fusible link with electrothermal feature	Specify degrees

Chapter 8 Symbols for Use in Electronic Fire and Smoke Detection and Notification System Drawings and Insurance Diagrams

8.1* Introduction.

8.1.1 This chapter presents symbols that shall be used in drawings and diagrams.

8.1.2* Symbol Presentation.

8.1.2.1* Symbol Shapes. The shape of symbols shall be as illustrated in Sections 8.2 through 8.6.

8.1.2.2 Screened Lines. Screened lines in the chapter shall not be considered part of the symbol but shall be used to represent the piping, wiring, or mounting surface associated with the symbol.

8.1.2.3 Symbol Scale. All scales for symbols on any one drawing shall be the same relative size.

8.1.2.4* Symbol Orientation. Symbols shall be oriented to the walls, piping, electrical lines, and so forth, to which they are attached.

8.2 Symbols for Control Panels. Symbols for control panels shall be as given in Table 8.2.

Table 8.2 Symbols for Control Units (Panels)

Symbol	Description
	Basic shape
AMP	Amplifier rack
ARCM	Area of refuge emergency communication system — master unit
ARCR	Area of refuge emergency communication system — remote unit
ACU	Autonomous control unit
BATT	Battery cabinet
CRT	Cathode ray tube
HVAC	Control panel for heating (H), ventilation (V), air conditioning (AC), exhaust (E), stairwell pressurization (P)
DACR	Digital alarm communicator receiver
DACT	Digital alarm communicator transmitter
ESR	Elevator status/recall
ECCU	Emergency communications control unit
FAA	Fire alarm annunciator
FAC	Fire alarm communicator

Table 8.2 *Continued*

Symbol	Description
FACP	Fire alarm control panel
FACU_D	Fire alarm control unit (dedicated)
FATC	Fire alarm terminal cabinet
TPR *n*	Fire alarm transponder n = transponder number
FFI	Fire fighter interface
FSCP xx	Fire suppression control panel xx denotes suppression type
FSCU xx	Fire suppression control unit xx denotes suppression type
GAP	Graphic annunciator panel
LCD	LCD annunciator/display
MFACU	Master fire alarm control unit
NAC_n	Notification circuit power booster, extender panel n = unit number
	Power panel
PRE	Pre-action system/control unit
PRN	Printer
PPCU	Protected premises control unit (local)

Table 8.2 ***Continued***

Symbol	Description
PP	Purge panel
RP	Relay panel
RSFACU	Releasing service fire alarm control unit
MIC	Remote voice evacuation microphone
EVAC_n	Remotely located evacuation amplifier cabiner
SAP	Sprinkler alarm panel
UPS	Uninterruptible power supply
EVAC	Voice evacuation control unit
WCU	Wireless control unit
Fire Suppression/Releasing Service Control Unit Types:	
RSFACU_{A}	Aerosol
RSFACU_{CO_2}	Carbon dioxide
RSFACU_{CA}	Clean agent
RSFACU_{DL}	Deluge fire sprinkler
RSFACU_{DC}	Dry chemical

Table 8.2 ***Continued***

Symbol	Description
FACI	Fire alarm control interface
FPC	Fire pump controller
RSFACU_{FO}	Foam
RSFACU_{HL}	Halon
MNS	Mass notification system interface
OCU	Operating control unit
RSFACU_{WM}	Water mist
RSFACU_{WC}	Wet chemical

8.3* Symbols for Fire Alarms, Detection, and Related Equipment — Signal Initiating Devices and Activation Switches. Symbols for signal initiating devices and activation switches shall be as given in Table 8.3.

Table 8.3 Symbols for Signal Initiating Devices and Activation Switches

Symbol	Description
Abort Switch Types:	
	Abort switch — basic shape
	Abort switch

(continues)

Table 8.3 *Continued*

Symbol	Description
	Aerosol release abort station
	Clean agent
	Deluge fire sprinkler
	Dry chemical
	Foam
	Halon
	Manual releasing station
	Preaction
	Water mist
	Wet chemical
Addressable Modules:	
	Addressable input monitor module
	Addressable input/output module; # denotes number of inputs and outputs

Table 8.3 *Continued*

Symbol	Description
	Addressable output control module
	Isolation module
Automatic Detection Type:	
	Automatic detection and supervisory devices — basic shape
Flame Detection Types:	
	Flame detector basic shape XX = detection type
	Combination ultraviolet/infrared
	Infrared detector
	Ultraviolet detector
	Visible radiation detector
Gas Detection Types:	
	Gas detector/sensor basic shape XX = gas type
	Carbon dioxide detector
	Carbon monoxide detector

Table 8.3 ***Continued***

Symbol	Description
	Hydrogen chloride detector
	Methane detector
Heat Detection Types:	
	Heat detector/sensor — XX = type basic shape
	Combination rate of rise/fixed temperature
	Fixed temperature
	Heat detector — line type
	Heat detector/sensor (thermal detection) orientation not to be changed
	Rate compensation
	Rate of rise only
Interface and Supervisory Devices:	
$\boxed{\text{EOL}}_{C}$	End of line device — capacitor
$\boxed{\text{EOL}}_{D}$	End of line device — diode
$\boxed{\text{EOL}}_{Rl}$	End of line device — relay

Table 8.3 ***Continued***

Symbol	Description
$\boxed{\text{EOL}}_{Re}$	End of line device — resistor
$\boxed{\text{WF}}$	Flow detector/switch
$\boxed{\text{HT}}$	High temperature switch
$\boxed{\text{LS}}$	Level detector/switch
$\boxed{\text{LT}}$	Low temperature switch
$\boxed{\text{MR}}$	Main/Reserve
$\boxed{\text{MD}}$	Maintenance/Disconnect switch
$\boxed{\text{RL}}$	Non-addressable output relay
$\boxed{\text{PS}}$	Pressure detector/switch
	Solenoid valve
$\boxed{\text{SS}}$	Surge suppressor
$\boxed{\text{TSS}}$	Temperature supervisory switch
	Transfer switch — automatic with handle
	Transfer switch — manual with handle

(continues)

Table 8.3 *Continued*

Symbol	Description
VS	Valve supervisory switch
VS	Valve with integral supervisory switch
W	Water detector
Manual Fire Alarm Box Types:	
	Manual station — basic shape
A	Aerosol
CO_2	Carbon dioxide
CA	Clean agent
DL	Deluge fire sprinkler
DK	Drill key
DC	Dry chemical
MB	Fire alarm master box
FO	Foam
HL	Halon
PRE	Preaction

Table 8.3 *Continued*

Symbol	Description
F	Pull station/fire alarm box
WM	Water mist
WC	Wet chemical
Smoke Detection/Sensor Types:	
S	Smoke detector/sensor — basic shape orientation not to be changed
S AS	Air sampling
S ID	In duct
S I	Ionization
S P	Photoelectric
S R	Relay base
S R CO	Smoke/heat detector/carbon monoxide detector
S R	Smoke/heat detector/sensor combination
SS	Smoke alarm (single station)

Table 8.3 *Continued*

Symbol	Description
	Smoke detector/sensor— beam receiver
	Smoke detector/sensor — beam transmitter
	Smoke detector/sensor — XX = type
	Smoke detector/sensor for duct
	Sounder base

8.4 Notification Appliances.

8.4.1 Notification appliance subscripts shall be applied to symbols as required for clarification *(see Table 8.4.1)*.

Table 8.4.1 Notification Appliance Subscripts

Subscript	Meaning
C	Ceiling mount
H	High audible setting
L	Low audible setting
MNS	Mass notification system
P	Pendent
RI	Remote indicator
SL	Signal light
nW	Wattage setting (*n* = speaker tap)
WP	Weatherproof
WG	Wire guard

8.4.2 Notification Appliances. Symbols for notification appliances shall be as given in Table 8.4.2.

Table 8.4.2 Symbols for Notification Appliances

Symbol	Description
	Audible appliance — basic shape
	Bell — single stroke
	Bell — trouble
	Bell — vibrating
	Ceiling mount indicator
	Chime
	Chime — electronic
	Combination horn/visible CD = candela rating/setting
	Combination speaker/visible W = wattage CD = candela rating/setting
	Gong
	Horn only
	Mini-horn

(continues)

Table 8.4.2 *Continued*

Symbol	Description
	Remote alarm indicating and test switch
	Remote indicator
	Rotating beacon
	Speaker only, ceiling mount — denote wattage tap
	Speaker only, wall mount — denote wattage tap
	Visible only (strobe) — ceiling mount CD = candela rating/setting
	Visible only (strobe) — wall mount CD = candela rating/setting

8.4.3 Emergency Communications Notification Appliances. Symbols for emergency communication appliances shall be as given in Table 8.4.3.

Table 8.4.3 Symbols for Emergency Communications Notification Appliances

Symbol	Description
	Combination speaker/visible — ceiling mount CD = candela rating/setting, W = wattage
	Combination speaker/visible — wall mount CD = candela rating/setting, W = wattage
	Emergency textual visible appliance

Table 8.4.3 *Continued*

Symbol	Description
	Visible only (strobe) — ceiling mount CD = candela rating/setting
	Visible only (strobe) — wall mount CD = candela rating/setting

8.5 Related Equipment. Symbols for related equipment shall be as given in Table 8.5.

Table 8.5 Symbols for Related Equipment

Symbol	Description
	Air sampling detector piping
	Door closer
	Door holder
	End of line resistor
	Fire service or emergency phone station — accessible
	Fire service or emergency phone station — basic shape
	Fire service or emergency phone station — handset
	Fire service or emergency phone station — jack
	Floor Warden Station

Table 8.5 *Continued*

Symbol	Description
	Integrated smoke sensor and door closer
JB	Junction box
SA	Sync adapter module (strobe synchronization)
WT	Watchman's tour station

8.6 Symbols for Smoke/Pressurization Control. Symbols for smoke/pressurization controls shall be as given in Table 8.6.

Table 8.6 Symbols for Smoke/Pressurization Controls

Symbol	Description	Comments
	Dampers — barometric	
	Dampers — fire	
	Dampers — fire/smoke	
	Dampers — motorized fire/smoke	
	Dampers — smoke	

Table 8.6 *Continued*

Symbol	Description	Comments
	Fans — duct	Arrow indicates direction of flow
	Fans — general	Arrow indicates direction of flow
	Fans — roof	Arrow indicates direction of flow
	Fans — wall	Arrow indicates direction of flow
	Hand (manual)/off-automatic	
	Pressurized stairwell	Orient as required for base or head injection
	Purge controls — manual control	
	Ventilation openings	Orient as required for intake or exhaust

Chapter 9 Symbols for Use in Pre-Incident Planning Sketches

9.1 Introduction.

9.1.1* This chapter presents symbols that shall be used in pre-incident planning sketches.

9.1.2* Symbol Shapes. The symbol shapes shall be chosen for their ease of reproduction by either freehand drawing or with the use of templates.

9.2* Access Features, Assessment Features, Ventilation Features, and Utility Shutoffs. Symbols for access features, assessment features, ventilation features, and utility shutoffs shall be as given in Table 9.2.

Table 9.2 Symbols for Access Features, Assessment Features, Ventilation Features, and Utility Shutoffs

Symbol	Description	Comments
	Access features, assessment features, ventilation features, and utility shutoffs	Basic shape
	Access feature — fire department access point	
	Access feature — fire department key box	
	Access feature — roof access	
	Assessment feature — fire alarm annunciator panel	
	Assessment feature — fire alarm reset panel	
	Assessment feature — fire alarm voice communication panel	
	Assessment feature — smoke control and pressurization panel	
	Assessment feature — sprinkler system water flow bell	
	Ventilation feature — skylight	
	Ventilation feature — smoke vent	
	Utility shutoff — electric	

Table 9.2 *Continued*

Symbol	Description	Comments
	Utility shutoff — domestic water	
	Utility shutoff — gas	
	Specific variations — LP-Gas shutoff	
	Specific variations — natural gas shutoff	
	Specific variations — compressed natural gas shutoff	

9.3 Detection/Extinguishing Equipment. Symbols for detection/extinguishing equipment shall be as given in Table 9.3.

Table 9.3 Symbols for Detection/Extinguishing Equipment

Symbol	Description	Comments
	Detection/ extinguishing equipment	Basic shape
	Duct detector	
	Heat detector	
	Smoke detector	
	Flow switch (water)	
	Manual station — pull station/fire alarm box	

Table 9.3 ***Continued***

Symbol	Description	Comments
◇ TS	Tamper switch	
◇ HL	Halon system	
◇ DC	Dry chemical system	
◇ CO_2	Carbon dioxide system	
◇ WC	Wet chemical system	
◇ FO	Foam system	
◇ CA	Clean agent system	
◇ BSD	Beam smoke detector	

9.4 Water Flow Control Valves and Water Sources. Symbols for water flow control valves and water sources shall be as given in Table 9.4.

Table 9.4 Symbols for Water Flow Control Valves and Water Sources

Symbol	Description	Comments
○	Water flow control valves and water sources	Basic shape
○ PIV	Post-indicator valve	
○ RV	Riser valve	

Table 9.4 ***Continued***

Symbol	Description	Comments
○ ZV	Sprinkler zone valve	
○ SCV	Sectional control valve	
○ HC	Hose cabinet or connection	
○ WH	Wall hydrant	
○ TH	Test header (fire pump)	
○ TC	Inspector's test connection	
○ FH	Fire hydrant	
○ FDC	Fire department connection	
○ DS	Drafting site	
○ WT	Water tank	

9.5 Equipment Rooms. Symbols for equipment rooms shall be as given in Table 9.5.

Table 9.5 Symbols for Equipment Rooms

Symbol	Description	Comments
	Equipment rooms	Basic shape
AC	Air-conditioning equipment room	AHUs = air-handling units
EE	Elevator equipment room	
EG	Emergency generator room	
FP	Fire pump room	
TE	Telephone equipment room	
BR	Boiler room	
ET	Electrical/ transformer room	

9.6* Identification of Hazardous Materials. NFPA 704 shall be permitted to be used to identify the location of hazardous materials within a structure.

Chapter 10 Symbology for Emergency Management Mapping

10.1 Damage Operational Symbols. Table 10.1 shall be used to cross-reference the damage operational symbols with their definitions.

Table 10.1 Damage Operational Symbology Reference

Symbol Types and Terms	Symbols	Definitions
Incident (No levels) (violet)		Not applicable
Natural Event (No levels) (black)		Not applicable
Operation (Level 1) (green)		Fully operational/open
Operation (Level 2) (blue)		Operational, but filled to capacity or otherwise closed
Operation (Level 3) (orange)		Operational, but partially damaged or partially incapacitated
Operation (Level 4) (red)		Destroyed or totally incapacitated
Infrastructure (Level 1) (green)		Fully operational/open
Infrastructure (Level 2) (blue)		Operational, but filled to capacity or otherwise closed

Table 10.1 *Continued*

Symbol Types and Terms	Symbols	Definitions
Infrastructure (Level 3) (orange)		Operational, but partially damaged or partially incapacitated
Infrastructure (Level 4) (red)		Destroyed or totally incapacitated

10.2 Operations Symbology.

10.2.1 Organizations, services, capabilities, or resources available during or implemented due to an emergency management situation.

10.2.2 Table 10.2.2 shall be used to cross-reference the operations symbols with their definitions.

Table 10.2.2 Operations Symbology Reference

Symbol Types and Terms	Symbols	Keystroke	Definitions
Operations Background Symbol (Background)		!	The background fill shape for the Operations symbol, Level 1
Operations Frame Symbol (Frame)		#	The frame shape for the Operations symbol, Level 1
Emergency Medical Operation (Theme)		A	Urgent and unexpected medicinal treatment and/or transport during serious situations that require immediate action[1]
Ambulance (Emergency Medical Feature)		B	A vehicle for taking sick or wounded people to and from a hospital
EMT Station Locations (Emergency Medical Feature)		C	The locus of an emergency medical team
Medical Evacuation Helicopter Station (Emergency Medical Feature)		D	The locus of an emergency helicopter landing pad, utilized to transport severely injured persons
Health Department Facility (Emergency Medical Feature)		E	The locus of a facility operated by a public institution that is dedicated to promotion of health and prevention of disease at the community, county, state, or national level[2]

(continues)

Table 10.2.2 *Continued*

Symbol Types and Terms	Symbols	Keystroke	Definitions
Hospital (Emergency Medical Feature)		F	The locus of an institution where the sick or injured are given medical or surgical care
Hospital Ship (Emergency Medical Feature)		G	The locus of a ship where the sick or injured are given medical or surgical care
Medical Facilities Outpatient (Emergency Medical Feature)		H	The locus of a facility providing medical treatment to patients whose sickness or injury does not require hospitalization
Morgue (Emergency Medical Feature)		I	The locus of a place where the bodies of persons found dead are kept until identified and claimed by relatives or released for burial[3]
Pharmacies (Emergency Medical Feature)		J	The locus of a place where medicines are compounded or dispensed[3]
Triage (Emergency Medical Feature)		K	The locus of a place where sorting and allocation of treatment to patients (especially victims of war or disaster) are performed according to a system of priorities designed to maximize the number of survivors[3]
Emergency Operation (Theme)		L	Those actions taken during the emergency period to protect life and property, care for the people affected, and temporarily restore essential community services[4]
Emergency Collection/Evacuation Point (Emergency Operation Feature)		M	A designated place where displaced persons or victims of war or disaster are assembled and/or evacuated from
Emergency Incident Command Center (Emergency Operation Feature)		N	The physical location from which an incident commander manages an incident[5]
Emergency Operations Center (Emergency Operation Feature)		O	The physical location where an organization comes together during an emergency to coordinate response and recovery actions and resources and make management decisions[6]

Table 10.2.2 *Continued*

Symbol Types and Terms	Symbols	Keystroke	Definitions
Emergency Public Information Center (Emergency Operation Feature)		P	No definition
Emergency Public Service Center (Emergency Operation Feature)		Q	No definition
Emergency Shelters (Emergency Operation Feature)		R	The locus of a designated emergency/relief shelter
Emergency Staging Areas (Emergency Operation Feature)		S	A designated place where emergency response forces, equipment, and supplies are assembled prior to engagement in operations
Emergency Teams (Emergency Operation Feature)		T	The locus of an emergency response team
Emergency Water Distribution Center (Emergency Operation Feature)		U	A place where potable water is distributed to displaced persons or victims of war or disaster
Emergency Food Distribution Centers (Emergency Operation Feature)		V	A place where food is distributed to displaced persons or victims of war or disaster
Fire Suppression Operation (Theme)		W	The extinguishing of a burning (and flaming) object by means of applying an agent, such as water[7]
Fire Hydrant (Fire Suppression Feature)		X	A discharge pipe with a valve and spout from which water can be drawn from a water main in sufficient volume and at sufficient pressure for fire-fighting purposes[8]
Other Water Supply Location (Fire Suppression Feature)		Y	Any source of water other than a fire hydrant that is sufficient for the purpose of fire fighting
Fire Station (Fire Suppression Feature)		Z	A facility housing fire-fighting equipment and/or personnel

(continues)

Table 10.2.2 ***Continued***

Symbol Types and Terms	Symbols	Keystroke	Definitions
Law Enforcement Operation (Theme)		a	Act of ensuring obedience to the laws[9]
ATF (Law Enforcement Feature)		b	A locus of U.S. Bureau of Alcohol, Tobacco, and Firearms facilities, equipment, or personnel
Border Patrol (Law Enforcement Feature)		c	A locus of U.S. Border Patrol facilities, equipment, or personnel
Customs Service (Law Enforcement Feature)		d	A locus of U.S. Customs Service facilities, equipment, or personnel
DEA (Law Enforcement Feature)		e	A locus of U.S. Drug Enforcement Administration facilities, equipment, or personnel
DOJ (Law Enforcement Feature)		f	A locus of U.S. Department of Justice facilities, equipment, or personnel
FBI (Law Enforcement Feature)		g	A locus of Federal Bureau of Investigation facilities, equipment, or personnel
Police (Law Enforcement Feature)		h	A locus of federal, state, or local police facilities, equipment, or personnel
Prison (Law Enforcement Feature)		i	A facility for the confinement of persons convicted of serious crimes[3]
Secret Service (Law Enforcement Feature)		j	A locus of U.S. Secret Service facilities, equipment, or personnel
TSA (Law Enforcement Feature)		k	A locus of U.S. Transportation Security Administration facilities, equipment, or personnel

Table 10.2.2 ***Continued***

Symbol Types and Terms	Symbols	Keystroke	Definitions
U.S. Coast Guard (Law Enforcement Feature)		l	A locus of U.S. Coast Guard facilities, equipment, or personnel
U.S. Marshals Service (Law Enforcement Feature)		m	A locus of U.S. Marshals Service facilities, equipment, or personnel
Sensor Operation (Theme)		n	A device that receives and responds to a signal or stimulus[9]
Biological Sensor (Sensor Operation Feature)		o	A device designed to respond to the presence of one or more biological substances and to transmit a resulting impulse[10]
Chemical Sensor (Sensor Operation Feature)		p	A device designed to respond to the presence of one or more chemicals and to transmit a resulting impulse[10]
Intrusion Sensor (Sensor Operation Feature)		q	A device designed to respond to physical penetration of, or attempts to physically penetrate, a protected area or spatial volume and to transmit a resulting impulse[10]
Nuclear Sensor (Sensor Operation Feature)		r	A device designed to respond to one or more decay product(s) of one or more radioactive nuclides and to transmit a resulting impulse[11]
Radiological Sensor (Sensor Operation Feature)		s	A device designed to respond to one or more decay product(s) of one or more radioactive nuclides and to transmit a resulting impulse[11]

10.3 Incidents Symbology.

10.3.1 Table 10.3.2 shall be used to depict 8 themes and 42 features that symbolize a "cause of action" or a "source of disaster."

10.3.2 Table 10.3.2 shall be used to cross-reference the incidents symbols with their definitions.

Table 10.3.2 Incidents Symbology Reference

Symbol Types and Terms	Symbols	Keystroke	Definitions
Incidents Stage 01 Background Symbol (Background)		!	The background fill shape for the Incidents symbol, Level 1
Incidents Stage 01 Frame Symbol (Frame)		#	The frame shape for the Incidents symbol, Level 1
Civil Disturbance Incident (Theme)		A	Human activities resulting in the disrupting of services or requiring varying levels of support, law enforcement, or attention
Civil Demonstrations (Civil Disturbance Feature)		B	A public display of group feelings toward a person or cause[1]
Civil Displaced Population (Civil Disturbance Feature)		C	Persons or groups of people who have been forced or obliged to flee or to leave their homes or places of habitual residence, in particular as a result of or in order to avoid the effects of armed conflict, violations of human rights, or natural or human-made disasters[2]
Civil Rioting (Civil Disturbance Feature)		D	A public disturbance involving (1) an act or acts of violence by one or more persons part of an assemblage of three or more persons, which act or acts shall constitute a clear and present danger of, or shall result in, damage or injury to the property of any other person or to the person of any other individual, or (2) a threat or threats of the commission of an act or acts of violence by one or more persons part of an assemblage of three or more persons having, individually or collectively, the ability of immediate execution of such threat or threats, where the performance of the threatened act or acts of violence would constitute a clear and present danger of, or would result in, damage or injury to the property of any other person or to the person of any other individual[3]
Criminal Activity Incident (Theme)		E	An unlawful pursuit or action in which an individual participates[4]

Table 10.3.2 *Continued*

Symbol Types and Terms	Symbols	Keystroke	Definitions
Bomb Threat (Criminal Activity Feature)		F	A warning of the possible presence of a bomb or expression of the intention to detonate a bomb
Bomb (Criminal Activity Feature)		G	An explosive device fused to detonate under specific conditions[5]
Bomb Explosion (Criminal Activity Feature)		H	A violent outburst resulting from detonation of a chemical or nuclear explosive or from the loss of a high pressure vessel's integrity
Looting (Criminal Activity Feature)		I	Burglary committed within an affected area during an emergency[6]
Poisoning (Criminal Activity Feature)		J	Use of a poisonous substance to injure or kill[1]
Shooting (Criminal Activity Feature)		K	Use of a firearm to kill or injure or to damage property[1]
Fire Incident (Theme)		L	The destructive act of something burning, caused by electrical or technological malfunction, lightning, arson, human error, or human negligence
Hot Spot (Fire Incident Feature)		P	An area of intensified fire activity and increased heat or a particularly active part of a fire
Non-Residential Fire (Fire Incident Feature)		Q	A fire that originates at or affects a non-residential or commercial facility, resulting in partial damage or total destruction of the structure and/or bodily injury, smoke inhalation, or death
Origin (Fire Incident Feature)		R	Location of where the fire started[7]

(continues)

Table 10.3.2 *Continued*

Symbol Types and Terms	Symbols	Keystroke	Definitions
Residential Fire (Fire Incident Feature)		S	A fire affecting a home or housing complex, resulting in partial or total destruction of the structure and/or bodily injury, smoke inhalation, or death
School Fire (Fire Incident Feature)		T	A fire that originates at or affects an educational facility, resulting in partial or total destruction of the structure and/or bodily injury, smoke inhalation, or death
Smoke (Fire Incident Feature)		U	The visible products of combustion rising above the fire[8]
Special Needs Fire (Fire Incident Feature)		V	A fire that affects special treatment facilities, such as nursing homes or assisted living centers, resulting in partial or total destruction of the structure and/or bodily injury, smoke inhalation, or death
Wild Fire (Fire Incident Feature)		W	An uncontrolled fire in a wooded area[9]
Hazardous Incident (Theme)		X	See footnote.[10]
Chemical Agent (Hazardous Incident Feature)		Y	A chemical substance that is intended for use in military operations to kill, resulting in psychological disorientation, serious injury, incapacitation, or death[11]
Corrosive Material (Hazardous Incident Feature)		Z	Uncontrolled or potentially dangerous presence of a liquid or solid that causes full thickness destruction of human skin at the site of contact within a specified period of time
Dangerous When Wet (Hazardous Incident Feature)		a	Uncontrolled or potentially dangerous presence of a material that, by contact with water, is liable to become spontaneously flammable or to give off flammable or toxic gas at a rate greater than 1 L/hr per kilogram of the material per hour (0.48 qt/hr/lb)
Explosive (Hazardous Incident Feature)		b	Uncontrolled or potentially dangerous presence of any substance or article, including a device that is designed to function by explosion (i.e., an extremely rapid release of gas and heat) or that, by chemical reaction within itself, is able to function in a similar manner even if not designed to function by explosion

Table 10.3.2 ***Continued***

Symbol Types and Terms	Symbols	Keystroke	Definitions
Flammable Gas (Hazardous Incident Feature)		c	Uncontrolled or potentially dangerous presence of any material that is a gas at 20°C (68°F) or less and 101.3 kPa (14.7 psia) of pressure [a material that has a boiling point of 20°C (68°F) or less at 101.3 kPa (14.7 psia)], that is ignitible at 101.3 kPa (14.7 psia) when in a mixture of 13 percent or less by volume with air, or that has a flammable range at 101.3 kPa (14.7 psia) with air of at least 12 percent regardless of the lower limit
Flammable Liquid (Hazardous Incident Feature)		d	Uncontrolled or potentially dangerous presence of a liquid having a flash point of not more than 60.5°C (141°F)
Flammable Solid (Hazardous Incident Feature)		e	Uncontrolled or potentially dangerous presence of desensitized explosives that when dry are explosives of Class 1, which are wetted with sufficient water, alcohol, or plasticizer to suppress explosive properties
Nonflammable Gas (Hazardous Incident Feature)		f	Uncontrolled or potentially dangerous presence of any material (or mixture) that exerts in the packaging an absolute pressure of 280 kPa (40.6 psia) or greater at 20°C (68°F) and is not classified as a flammable gas
Organic Peroxides (Hazardous Incident Feature)		g	No definition
Oxidizers (Hazardous Incident Feature)		h	Uncontrolled or potentially dangerous presence of a material that can, generally by yielding oxygen, cause or enhance the combustion of other materials
Radioactive Material (Hazardous Incident Feature)		i	Uncontrolled or potentially dangerous presence of any material having a specific activity greater than 70 Bq/g (17 μCi/oz)
Spontaneously Combustible (Hazardous Incident Feature)		j	Uncontrolled or potentially dangerous presence of a liquid or solid that, even in small quantities and without an external ignition source, can ignite within five (5) minutes after coming in contact with air or a material that, when in contact with air and without an energy supply, is liable to self-heat
Toxic Gas (Hazardous Incident Feature)		k	Uncontrolled or potentially dangerous presence of a gas that presents a hazard to human health

(continues)

Table 10.3.2 ***Continued***

Symbol Types and Terms	Symbols	Keystroke	Definitions
Toxic and Infectious (Hazardous Incident Feature)		l	Uncontrolled or potentially dangerous presence of a poisonous substance that is a specific product of the metabolic activities of a living organism and is usually very unstable and can easily be transferred between organisms
Unexploded Ordnance (Hazardous Incident Feature)		m	Uncontrolled or potentially dangerous presence of an unexploded weapon or ammunition
Air Incident (Theme)		n	An event involving aircraft resulting in damage, bodily injury, death, or the disruption of transportation service
Air Accident (Air Incident Feature)		o	A sudden, unexpected event involving aircraft resulting in fuselage damage, bodily injury, death, and/or the disruption of transportation service, prompting emergency landing procedures or uncontrolled impact with the ground
Air Hijacking (Air Incident Feature)		p	The unexpected, unlawful, and forceful seizure of control aboard an aircraft by an individual or group of individuals resulting in passenger and crew endangerment, injury or death, and/or the redirection of flight destination[12]
Marine Incident (Theme)		q	An event involving a boat or ship and resulting in damage, bodily injury, death, or the disruption of transportation service
Marine Accident (Marine Incident Feature)		r	A sudden, unexpected event involving a boat or ship and resulting in vessel submerging, damage, bodily injury, death, and/or the disruption of transportation service
Marine Hijacking (Marine Incident Feature)		s	The unexpected, unlawful, and forceful seizure of control aboard a boat or ship by an individual or group of individuals resulting in passenger and crew endangerment, injury or death, and/or the redirection of destination[12]
Rail Incident (Theme)		t	An event involving a train and resulting in damage, bodily injury, death, or the disruption of transportation service
Rail Accident (Rail Incident Feature)		u	A sudden, unexpected event involving a wheeled or tracked vehicle resulting in derailment, damage, bodily injury, death, and/or the disruption of transportation service

Table 10.3.2 ***Continued***

Symbol Types and Terms	Symbols	Keystroke	Definitions
Rail Hijacking (Rail Incident Feature)		v	The unexpected, unlawful, and forceful seizure of control aboard a wheeled or tracked vehicle by an individual or group of individuals resulting in passenger and crew endangerment, injury or death, and/or the redirection of destination[12]
Vehicle Incident (Theme)		w	An event involving a wheeled or tracked vehicle and resulting in damage, bodily injury, death, or the disruption of transportation service
Vehicle Accident (Vehicle Incident Feature)		x	A sudden, unexpected event involving a vehicle and resulting in damage, bodily injury, death, and/or the disruption of transportation service
Vehicle Hijacking (Vehicle Incident Feature)		y	The unexpected, unlawful, and forceful seizure of control aboard a vehicle by an individual or group of individuals resulting in passenger and crew endangerment, injury or death, and/or the redirection of destination[12]

10.4 Natural Events Symbology.

10.4.1 A natural event shall be a phenomenon found in or created by naturally occurring conditions.

10.4.2 Table 10.4.2 shall be used to cross-reference the natural events symbols with their definitions.

Table 10.4.2 Natural Events Symbology Reference

Symbol Types and Terms	Symbols	Keystroke	Definition
Natural Events Stage 01 Background Symbol (Background)		!	The background fill shape for the Natural Events symbol, Level 1
Natural Events Stage 01 Frame Symbol (Frame)		#	The frame shape for the Natural Events symbol, Level 1
Geologic (Theme)	Reserved		
Aftershock (Geologic Feature)		A	An earthquake that follows a larger earthquake and originates at or near the latter's focus[1]
Avalanche (Geologic Feature)		B	A large mass of snow, ice, soil, or rock, or mixtures of these materials, falling, sliding, or flowing very rapidly under the force of gravity[1]
Earthquake Epicenter (Geologic Feature)		C	The point on the earth's surface directly above the focus of an earthquake[1]
Landslide (Geologic Feature)		D	A general term for a wide variety of processes and landforms involving the down slope movement under the force of gravity of masses of soil and rock material[1]
Subsidence (Geologic Feature)		E	Sinking or downward settling of the Earth's surface[1]
Volcanic Eruption (Geologic Feature)		F	The ejection of volcanic materials (lava, pyroclasts, and volcanic gases) from a vent or fissure in the Earth's crust[1]
Volcanic Threat (Geologic Feature)		G	A vent or fissure in the Earth's crust where volcanic eruption is believed to be imminent[2]

Table 10.4.2 ***Continued***

Symbol Types and Terms	Symbols	Keystroke	Definition
Hydro-Meteorologic (Theme)	Reserved		
Drizzle (Hydro-Meteorologic Feature)		H	Sometimes called *mist*; very small, numerous, and uniformly dispersed water droplets that appear to float while following air currents and that, unlike fog droplets, fall to the ground
Drought (Hydro-Meteorologic Feature)		I	A period of abnormally dry weather sufficiently prolonged for the lack of water to cause a serious hydrologic imbalance across the affected area. Drought severity depends upon the degree of moisture deficiency, the duration, and (to a lesser extent) the size of the affected area. In general, the term should be reserved for periods of moisture deficiency that are relatively extensive in both space and time.
Flood (Hydro-Meteorologic Feature)		J	A relatively high stream flow that overtops the stream banks in any part of its course, covering land that is not normally under water[1]; a condition that occurs when water overflows the natural or artificial confines of a stream or other body of water, or accumulates by drainage over low-lying areas
Fog (Hydro-Meteorologic Feature)		K	A visible aggregate of minute water droplets suspended in the atmosphere near the Earth's surface [According to international definition, fog reduces visibility to less than 1 km ($\frac{5}{8}$ mi). Fog differs from clouds only in that the base of the fog is at the Earth's surface, while clouds are above the surface.]
Hail (Hydro-Meteorologic Feature)		L	Precipitation in the form of circular or irregular-shaped lumps of ice[3]
Inversion (Hydro-Meteorologic Feature)		M	A departure from the standard decrease or increase with altitude of value of an atmosphere property; almost always used to mean temperature inversion
Rain (Hydro-Meteorologic Feature)		N	Precipitation in the form of liquid water drops that have diameters greater than 0.5 mm (0.2 in.)
Sand Dust Storm (Hydro-Meteorologic Feature)		O	A strong wind carrying sand through the air, the diameter of most of the particles ranging from 0.08 mm to 1 mm (0 to 0.04 in.); in contrast to a dust storm, sand particles mostly confined to the lowest 0.6 m (2 ft) and rarely rising more than 15.2 m (50 ft) above the ground
Snow (Hydro-Meteorologic Feature)		P	Precipitation composed of white or translucent ice crystals, chiefly of complex branched hexagonal form and often agglomerated into snowflakes

(continues)

Table 10.4.2 ***Continued***

Symbol Types and Terms	Symbols	Keystroke	Definition
Thunderstorm (Hydro-Meteorologic Feature)		Q	A consequence of atmospheric instability that constitutes an overturning of layers in order to achieve a more stable atmosphere; generally produces lightning, thunder, strong gusts of wind, heavy rain, and sometimes hail
Tornado (Hydro-Meteorologic Feature)		R	A violently rotating column, or funnel, of air in contact with the ground and extending from the base of a thunderstorm[3]
Tropical Cyclone (Hydro-Meteorologic Feature)		S	The general term for a cyclone that originates over the tropical oceans
Tsunami (Hydro-Meteorologic Feature)		T	A great sea wave produced by an earthquake or volcanic eruption, characterized by high speed of propagation, long wavelength, long period, and low observable amplitude on the open ocean[1]; can reach enormous dimensions and has sufficient energy to travel across entire oceans; no connection with tides, as can be inferred from the commonly used term *tidal wave*
Infestation (Theme)	Reserved		
Bird Infestation (Infestation Feature)		U	A harassing or troublesome invasion of birds[4]
Insect Infestation (Infestation Feature)		V	A harassing or troublesome invasion of insects
Microbial Infestation (Infestation Feature)		W	A harassing or troublesome invasion of microbes
Reptile Infestation (Infestation Feature)		X	A harassing or troublesome invasion of reptiles
Rodent Infestation (Infestation Feature)		Y	A harassing or troublesome invasion of rodents

10.5 Infrastructures Symbology.

10.5.1 Infrastructure shall be the basic facilities, services, and installations needed for the functioning of a community or society, such as transportation and communications systems, water and power lines, and public institutions, including schools, post offices, and prisons.

10.5.2 Table 10.5.2 shall be used to cross-reference the infrastructures symbols with their definitions.

Table 10.5.2 Infrastructure Symbology Reference

Symbol Types and Terms	Symbols	Keystroke	Definitions
Infrastructures Background Symbol (Background)		!	The background fill shape for the Infrastructures symbol, Level 1
Infrastructures Frame Symbol (Frame)		#	The frame shape for the Infrastructures symbol, Level 1
Agriculture and Food Infrastructure (Theme)		$	Production and retail services of foodstuffs
Agricultural Laboratory (Agriculture and Food Feature)		%	Facilities used for scientific research in farming
Animal Feedlot (Agriculture and Food Feature)		&	Area designated for feeding livestock
Commercial Food Distribution Center (Agriculture and Food Feature)		(	Facility used for the disbursement of marketable foodstuffs
Farm/Ranch (Agriculture and Food Feature)		)	A piece of land on which crops or animals are raised
Food Production Center (Agriculture and Food Feature)		*	The locus where foodstuffs are produced
Food Retail (Agriculture and Food Feature)		+	Facility where foodstuffs are sold for a profit
Grain Storage (Agriculture and Food Feature)		’	Facility used for the housing of cereal seeds such as corn, wheat, or barley
Banking, Finance, and Insurance Infrastructure (Theme)		–	The management of money and other assets and their protection[1]

(continues)

Table 10.5.2 ***Continued***

Symbol Types and Terms	Symbols	Keystroke	Definitions
ATM (Banking, Finance, and Insurance Feature)		.	An unattended machine commonly located at a bank's exterior that dispenses money when a personal coded card is inserted[2]
Bank (Banking, Finance, and Insurance Feature)		/	A business establishment in which money is kept for saving for commercial purposes or is invested, supplied for loans, or exchanged[1]
Bullion Storage (Banking, Finance, and Insurance Feature)		0	A facility used to deposit and warehouse gold or silver bars or ingots[3]
Federal Reserve Bank (Banking, Finance, and Insurance Feature)		1	One of twelve regional banks that monitor and act as depositories for banks in their region[2]
Financial Exchange (Banking, Finance, and Insurance Feature)		2	A marketplace in which shares, options, and futures on stocks, bonds, commodities, and indexes are traded[4]
Financial Service Other (Banking, Finance, and Insurance Feature)		3	A business establishment, other than a bank, for the provision of financial or monetary-related products and services; a location that deals with money management business
Commercial Infrastructure (Theme)		4	The locus of where a business enterprise is undertaken[2]
Chemical Plant (Commercial Infrastructure Feature)		5	An industrial site where chemical substances and/or compounds are produced[2]
Firearm Manufacturer (Commercial Infrastructure Feature)		6	A location where hand weapons of explosive force when shot are mass produced[5]
Firearm Retailer (Commercial Infrastructure Feature)		7	A location where hand weapons of explosive force when shot are sold[6]
Hazardous Material Production (Commercial Infrastructure Feature)		8	The locus of where hazardous chemicals and/or substances are produced and stored under regulated conditions

Table 10.5.2 ***Continued***

Symbol Types and Terms	Symbols	Keystroke	Definitions
Hazardous Material Storage (Commercial Infrastructure Feature)		9	A storing location for a substance or combination of substances that, because of quantity, concentration, or physical, chemical, radiological, explosive, or infectious characteristics, poses a potential danger to humans and/or the environment[7]
Industrial Site (Commercial Infrastructure Feature)		:	The locus of an industrial facility or facilities used for the commercial production and selling of manufactured goods[1]
Landfill (Commercial Infrastructure Feature)		;	An area of land or an excavation in which wastes are placed for permanent disposal, and which is not a land application unit, surface impoundment, injection well, or waste pile[8]
Pharmaceutical Manufacturer (Commercial Infrastructure Feature)		=	The location where medicinal drugs are mass produced[9]
Superfund Site National Priorities List (Commercial Infrastructure Feature)		?	A location in the United States that has been contaminated by hazardous waste and identified by the Environmental Protection Agency as a candidate for cleanup because it poses a risk to human health and/or the environment[10]
Toxic Release Inventory (Commercial Infrastructure Feature)		@	The location according to a publicly available database of chemical and other toxic waste releases[10]
Educational Facilities Infrastructure (Theme)		A	A building or collection of buildings or places in which knowledge is provided[11]
College/University (Educational Facilities Feature)		B	An institution of higher learning offering courses of studies leading to bachelor's, master's, or doctoral degrees[12]
School (Educational Facilities Feature)		C	A facility for the primary and secondary education of children[13]
Energy Facilities Infrastructure (Theme)		D	A building or collection of buildings and/or places that generates and provides electrical power
Generation Station (Energy Facilities Feature)		E	A facility equipped with special equipment used for the production of heat or electricity[14]

(continues)

Table 10.5.2 *Continued*

Symbol Types and Terms	Symbols	Keystroke	Definitions
Natural Gas Facility (Energy Facilities Feature)		F	A location equipped with special equipment used to generate natural gas power
Nuclear Facility (Energy Facilities Feature)		G	A location equipped with special equipment used to generate nuclear power
Petroleum Facility (Energy Facilities Feature)		H	A building or place that provides and distributes petroleum gas
Propane Facility (Energy Facilities Feature)		I	A building or place that provides and distributes propane gas
Government Site Infrastructure (Theme)		J	The locus of where executive, legislative, and/or judicial activities take place in the service of the government
Military Infrastructure (Theme)		K	Refers collectively to the four major branches of the United States' armed forces as associated with armed services as contrasted with civilians
Military Armory (Military Feature)		L	A military structure where arms and ammunition and other military equipment are manufactured and stored, and also where training is given in the use of arms[2]
Military Base (Military Feature)		M	The locus of where military personnel, weapons, and supplies are located and also where attacks and other operations are coordinated and launched
Postal Service Infrastructure (Theme)		N	The system whereby letters and other parcels are transmitted and delivered via the post office
Postal Distribution Center (Postal Feature)		O	A U.S. Postal Service (USPS) facility where mail is sorted and routed
Post Office (Postal Feature)		P	A U.S. Postal Service (USPS) facility that directly delivers postal services to the public
Public Venue Infrastructure (Theme)		Q	An unrestricted place or places and events for a large gathering of people[1]

Table 10.5.2 *Continued*

Symbol Types and Terms	Symbols	Keystroke	Definitions
Church (Public Venues Feature)		R	A building for public and especially Christian worship[13]
Enclosed Facility (Public Venues Feature)		S	A roofed facility with walls
Mosque (Public Venues Feature)		T	A building used for public worship by Muslims[13]
Open Facility (Public Venues Feature)		U	An open-air facility with or without walls, for example, a stadium or a parking lot
Recreational Area (Public Venues Feature)		V	A place dedicated to the refreshment of strength and spirits after work[13]
Religious Institution (Public Venues Feature)		W	Any place of worship where religious services are held or prayers are said by a congregation loyal to a belief
Synagogue (Public Venues Feature)		X	The house of worship and communal center of a Jewish congregation[13]
Temple (Public Venues Feature)		Y	A building for Mormon sacred ordinances[13]
Special Needs Infrastructure (Theme)		Z	Of or relating to people who have specific needs, such as those associated with a disability[1]
Adult Day Care (Special Needs Feature)		[	The locus of a nonresidential facility that provides supervision and assisted living services to adults, typically during the daylight hours
Child Day Care (Special Needs Feature)		]	A service involving care for other people's children[1]
Elder Care (Special Needs Feature)		^	The locus of a nursing home or a residential assisted-living facility in which full-time care is provided for the chronically ill, disabled, and elderly

(continues)

Table 10.5.2 *Continued*

Symbol Types and Terms	Symbols	Keystroke	Definitions
Telecommunications Infrastructure (Theme)		‘	The electronic systems used in transmitting messages, as by telegraph, cable, telephone, radio, television, or computer[1]
Telecommunications Facility (Telecommunications Feature)		a	Any facility housing telecommunications equipment, studios, control rooms, or personnel
Telecommunications Tower (Telecommunications Feature)		b	A structure typically higher than its diameter and high relative to its surroundings to which telecommunications antennae are affixed[13]
Transportation Infrastructure (Theme)		c	Infrastructure, means of transport, and equipment necessary for the movement of passengers and/or goods
Air Traffic Control Facility (Transportation Feature)		d	A facility operated by the appropriate authority to promote the safe, orderly, and expeditious flow of air traffic[8]
Airport (Transportation Feature)		e	An area of land or other hard surface, excluding water, that is used or intended to be used for the landing and takeoff of aircraft and includes its buildings and facilities, if any[8]
Bridge (Transportation Feature)		f	A structure built over a gap to connect and maintain transportation flow between both sides of the gap[15]
Bus Station (Transportation Feature)		g	A terminal that serves bus passengers[2]
Ferry Terminal (Transportation Feature)		h	The location of a vehicle-carrying and commuter boat line terminus[1]
Helicopter Landing Site (Transportation Feature)		i	A site within a landing zone that contains one or more points for helicopters to land[16]
Lock (Transportation Feature)		j	An enclosed part of a canal or river equipped with gates for raising or lowering the level of water so that boats and other vessels can pass[15]

Table 10.5.2 *Continued*

Symbol Types and Terms	Symbols	Keystroke	Definitions
Maintenance Facility (Transportation Feature)		k	A location where vehicles, machines, or any other mechanical devices are serviced for inspection or repair[2]
Port (Transportation Feature)		l	A location on a waterway with facilities for loading and unloading ships and other vessels[1]
Rail Station (Transportation Feature)		m	A depot where tracked transport vehicles or trains load and/or unload passengers or goods[17]
Rest Stop (Transportation Feature)		n	A roadside facility at which motorists can purchase refreshments, use restrooms, and/or acquire area information
Ship Anchorage (Transportation Feature)		o	A location suitable for securely anchoring ships and other vessels[1]
Toll Facility (Transportation Feature)		p	A gate or booth at which money is collected before and/or after motorists enter or exit a toll road (turnpike)[15]
Traffic Control Point (Transportation Feature)		q	The location of absolute signals controlled by an operator to regulate and maintain transportation flow
Traffic Inspection Facility (Transportation Feature)		r	Permanent facility equipped with scales where motor (shipping) vehicles transporting goods on public highways are required to stop and obtain gross vehicle and/or axle weights[18]
Tunnel (Transportation Feature)		s	An underground passageway used to connect and maintain transportation flow between physical or human-built obstructions[15]
Water Supply Infrastructure (Theme)		t	The storage, disinfection, filtration, and provision of drinking water to the consumer/community by means of pipelines, pumps, water towers, wells, and other appurtenances[19]
Critical Valve (Water Supply Feature)		u	A valve that regulates the speed, flow, or pressure of a fluid[20]

(continues)

Table 10.5.2 ***Continued***

Symbol Types and Terms	Symbols	Keystroke	Definitions
Dam (Water Supply Feature)		v	A barrier constructed across a waterway to control the flow or raise the level of water[1]
Discharge Outfall (Water Supply Feature)		w	The volume of effluent that is released into receiving waters at a given location and within a given period of time[21]
Ground Well (Water Supply Feature)		x	An artificial excavation drilled into the ground for the purposes of withdrawing water from underground aquifers[22]
Pumping Station (Water Supply Feature)		y	Facility that lifts water up and over hills[23]
Reservoir (Water Supply Feature)		z	An off-steam water storage facility that is filled with water pumped from a river or stream[24]
Storage Tower (Water Supply Feature)		{	A large (usually metallic) container for holding gases or liquids[2]
Surface Water Intake (Water Supply Feature)		}	A pipe through which wastewater is transferred directly to another site[25]
Water Treatment Facility (Water Supply Feature)		~	A place designed to receive the wastewater from domestic sources and to remove materials that damage water quality and threaten public health and safety when discharged into receiving streams or bodies of water[22]

Chapter 11 Emergency Evacuation Diagrams and Plans

11.1 Introduction. This chapter shall provide requirements on the preparation of floor diagrams and plans, posted within a building, to show the egress evacuation paths and locations of equipment used during an emergency. Building emergency information shall be provided to instruct or guide occupants in how to report an emergency; when to evacuate to the outside evacuation assembly area, to a designated area of refuge, to an area of rescue assistance, or to a designated shelter area; when to remain in place; or when to employ any combination of these options.

11.2 Composition.

11.2.1 The composition of the diagrams shall be clear and simple and able to be quickly understood by occupants within the building. To avoid language barriers, graphic representation and symbols shall be used.

11.2.2* A plan shall show a minimum of two ways to exit from the location of where the diagram/plan is posted, when possible, show the entire floor plan, but when unable to provide a key plan highlighting the area shown in accordance with NFPA *101.* A plan shall show a minimum of two ways to exit from the location of where the diagram/plan is posted, showing the entire floor plan in accordance with NFPA *101.* When unable to show the entire floor plan, provide a key plan highlighting the area.

11.2.3 The symbols of this standard shall be used to make sure that a legend is provided on the diagram/plan explaining their meaning.

11.2.4 The size of text, symbols, and information shall allow visibility by all occupants.

11.2.5 The diagram shall be located at a height above the floor to be viewable by all occupants. Diagrams shall be located such that all employees and visitors will pass by during their stay in the building.

11.3* Orientation.

11.3.1 All diagrams shall be oriented with the top in the direction that the viewer is facing.

11.3.2 There shall be a notation showing the location of the viewer and their orientation with the "you are here" notation pointing up to the sign location. This shall be the most dominant graphic on the diagram.

11.4 Information Shown.

11.4.1 The information in 11.4.1.1 and 11.4.1.2 shall be shown on the plan area of the diagram or plan. Additional information shall be permitted to be added if it does not confuse the viewer during an emergency.

11.4.1.1 The means of egress from the viewers' location shall be shown. This shall include all exit locations, exit access paths, stairways, elevators, elevator lobbies, areas of refuge, areas of rescue assistance, shelter areas, and exterior outside evacuation assembly areas.

11.4.1.2 The equipment used during an emergency shall be shown in a key or legend. This key or legend shall include fire alarm pull stations, emergency phones, defibrillators (AED), fire extinguishers (if trained to use properly), or any other building-specific emergency equipment.

11.4.2 The diagram or plan shall provide emergency phone numbers.

11.4.3 The diagram or plan shall provide emergency evacuation guidelines describing the different emergency alert signals of when and what to do when the signals are sounded. If there are not any signals, the guidelines shall describe how the occupants will be instructed what to do in case of an emergency.

11.5 Construction. The diagram shall be constructed with materials that protect it from fading and wear.

Annex A Explanatory Material

Annex A is not a part of the requirements of this NFPA document but is included for informational purposes only. This annex contains explanatory material, numbered to correspond with the applicable text paragraphs.

A.3.2.2 Authority Having Jurisdiction (AHJ). The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A.3.2.4 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A.3.3.3 Referent. A referent can be abstract, such as a condition concept, function, relationship, fact, or action.

A.3.3.5 Supplementary Indicators. Effectiveness of symbols can be supplemented by figures, numbers, subscripts, or letter abbreviations. These supplementary indicators can be placed inside of, or adjacent to, the symbol as seen fit. A legend of these indicators, with their meaning, should accompany each set of documents on which they are used.

A.3.3.6 Symbol. Ideally, a symbol should be graphically simple, should be readily understood, should have a strong impact, and should be easily remembered.

A.4.1.2.3 Changes in line thickness, scale, or details are not recommended. In practice, symbols can be combined with other symbols or devices such as words and lighted panels to provide optimal visual alerting. This chapter does not specify viewing distance, size, or optimal combinations of symbols, words, or other presentations. The user is referred to other standards, such as those prepared by the NFPA Committee on Safety to Life and the ANSI Z535 Committee on Safety Signs and Colors, for such information.

A.4.1.3 Reflective material or self-luminous or photoluminescent materials can be used. Consideration needs to be given to the proper mounting of self-luminous or photoluminescent symbols in well-lighted locations to ensure charging by exposure to ambient light.

A.4.1.3.2.1 See Figure A.4.1.3.2.1.

A.4.1.3.4 Examples of combinations of symbols that can be used include Exit Symbol Arrow, Exit Symbol with International Symbol of Accessibility, and Exit Symbol with Arrow and International Symbol of Accessibility.

A.4.2 Use of the symbols is not restricted to the examples cited.

A.5.1.1 The purpose of this chapter is to present uniform fire-fighting symbols in order to improve communication wherever symbology is employed in order to provide information to fire fighters and other emergency responders.

This chapter provides uniformity in the selection of symbols that are intended to assist fire fighters in locating utilities and fire-fighting equipment.

A.5.1.2 In practice, symbols can be combined with other devices, such as words and lighted panels, to provide optimal visual alerting. This chapter does not specify viewing distance, size, or optimal combinations of symbols, words, and other presentations.

A.5.1.3 Reflective material or self-luminous or photoluminescent materials can be used. Consideration needs to be given to the proper mounting of self-luminous or photoluminescent symbols in well-lighted locations to ensure charging by exposure to ambient light.

A.5.1.3.1 Drawing scale, line thickness, and so forth are the subject of standards on drawing practice.

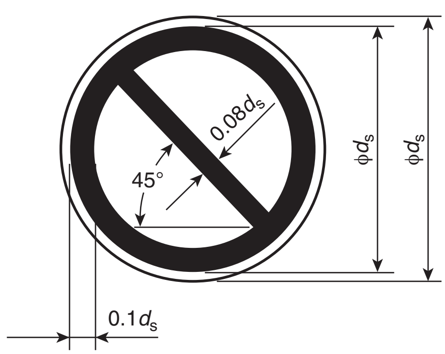
A.5.2 Use of the symbols is not restricted to the examples cited.

The symbol for fire hydrant (all types) shown in Table 5.2 can be of particular use where vehicles or snowfall frequently obscures hydrant locations.

A.6.1 This chapter on architectural and engineering symbols draws heavily on the symbols already developed by various societies, agencies, and industry.

The purpose of this chapter is to provide uniformity in the use of fire safety and related symbols in the preparation of drawings and diagrams.

The symbols in this chapter are intended to be simple, transferable by use of templates, and limited to those referents that are used repetitively in a set of drawings.



The colors of the sign shall be as follows:

Background color:	white
Circular band and diagonal bar:	red
Graphical symbol:	black
Border:	white

The safety color red shall cover at least 35 percent of the total area of the sign.

FIGURE A.4.1.3.2.1 Example of a Prohibition Symbol.

The symbols in this chapter are intended for, but not limited to, architectural and engineering drawings, fire detection and suppression drawings, and fire risk and/or loss analysis diagrams.

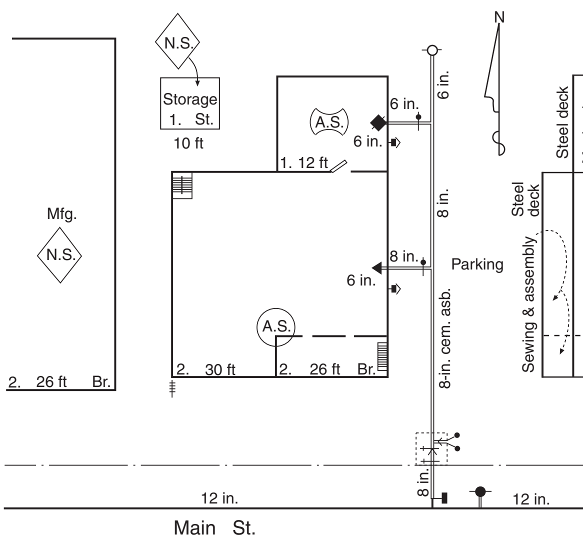
The effectiveness of the symbols in this chapter can be enhanced by the use of supplementary figures, subscripts, numbers, or letter abbreviations.

Devices infrequently used in a given set of drawings and diagrams are not standardized by this document. They usually are accompanied by narrative description, either on the drawing or in specifications.

A.6.1.2 Where appropriate, diagrams include, but are not limited to, the following *(see Figure A.6.1.2)*:

(1) Title block indicating the following:
  (a) Name of company or organization
  (b) Person making drawing and date of drawing
  (c) Name and location of facility involved
(2) "North" direction arrow properly oriented to the position of buildings shown.
(3) Scale of diagram, if used, or "not to scale." Scale can be given with a bar measurement if reduction copies are to be made.

A.6.1.2.1 Drawing scale, line thickness, and so forth, are the subject of standards on drawing practice.



For SI units: 1 in. = 25 mm; 1 ft = 0.305 m.

FIGURE A.6.1.2 Example of the Use of Symbols for Risk Analysis Diagram.

A.6.1.2.4 See Figure A.6.1.2.4(a) and Figure A.6.1.2.4(b) for examples of symbol orientation.

A.6.2.1.2 See Figure A.6.2.1.2 for examples of open-walled structures.

A.6.2.3 See Figure A.6.2.3 for an example of a street.

A.6.2.4 See Figure A.6.2.4 for examples of bodies of water.

A.6.2.5.2 See Figure A.6.2.5.2 for an example of a fence with a gate.

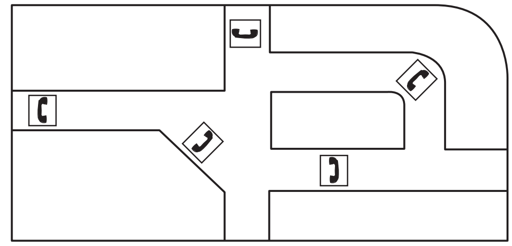


FIGURE A.6.1.2.4(a) Symbol Orientation — Example 1.

A.6.3.3 See Figure A.6.3.3(a) and Figure A.6.3.3(b) for examples of wall symbols.

See Figure A.6.3.3(a) for examples of parapet symbols used for a building.

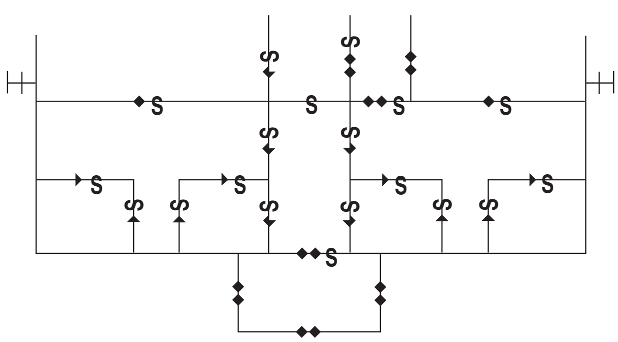

FIGURE A.6.3.3(a) Symbols Used to Note Wall Ratings and Parapets on Life Safety Plans and Risk Analysis Plans and Cross-Sections.

A.6.3.5 See Figure A.6.3.5 for an example of cross-section symbols used for a building.

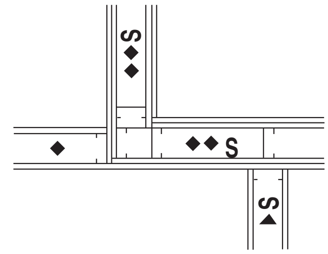

FIGURE A.6.3.3(b) Symbol Used to Note Wall Ratings on Design and Construction Documents.

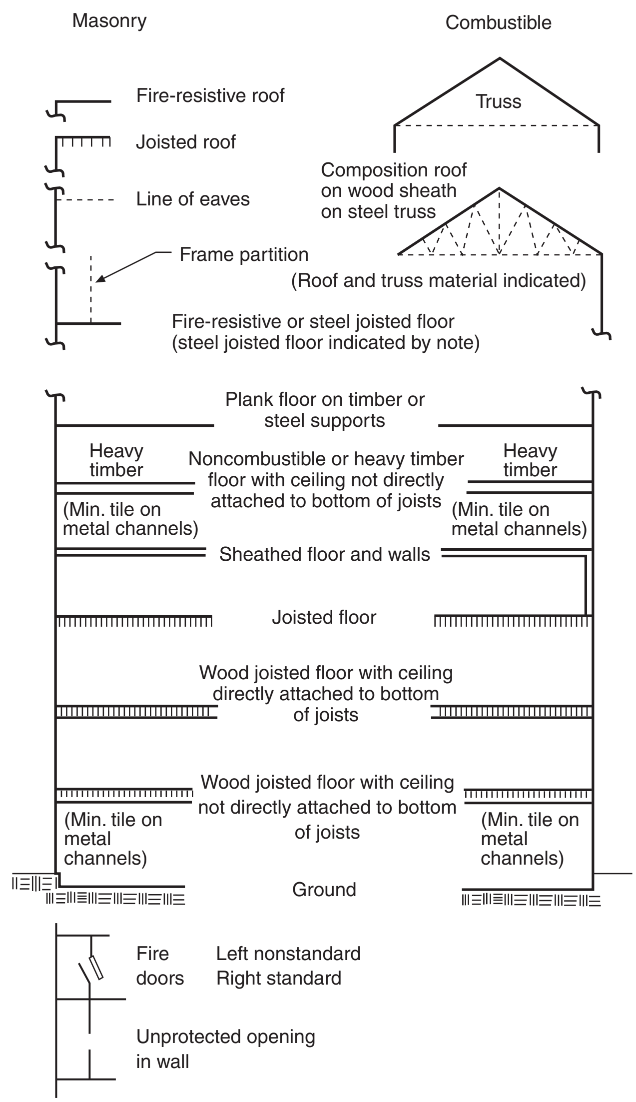

FIGURE A.6.3.5 Examples of Symbols and Notations Used for Fire Risk Analysis Cross Section. (Figure includes copyrighted material of Insurance Services Office with its permission. Copyright, Insurance Services Office, 1975.)

A.7.1 See A.6.1.

A.7.1.2 See A.6.1.2.

A.7.1.2.1 See A.6.1.2.1.

A.7.1.2.4 See A.6.1.2.4.

A.7.2 For private hydrant, one hose outlet; public hydrant, two hose outlets; public hydrant, two hose outlets and pumper connection; wall hydrant, two hose outlets; and private housed hydrant, two hose outlets, all shown in Table 7.2, symbol elements can be utilized in any combination to fit the type of hydrant.

A.7.6 These symbols are intended for use in identifying the type of system installed to protect an area within a building.

A.7.6.2 For sprinklers shown in Table 7.6.2, the temperature rating of the sprinkler and other characteristics can be shown via legends where a limited number of an individual type of sprinkler is called for by the design.

A.7.6.3 See also Table 7.2 for related symbols.

A.7.9 The electrothermal link (ETL) is a multipurpose dual-response fusible link/release device. These devices are used in various applications, such as smoke/damper control and door closures. The symbol should be shown with its rated thermal point.

A.8.1 See A.6.1.

A.8.1.2 See A.6.1.2.

A.8.1.2.1 See A.6.1.2.1.

A.8.1.2.4 See A.6.1.2.4.

A.8.3 Additional subscript identifiers can be included with a slash after the primary subscript to indicate such things as, for example, WP for weatherproof or EP for explosionproof.

For the manual station symbol shown in Table 8.3, electrical or mechanical actuation can be shown.

See NFPA 2001 for a generic list of clean agents.

The telephones referred to in the fire service or emergency telephone station symbols, shown in Table 8.3, are those for a dedicated system for fire and related emergencies.

Temperature rating of heat detectors, in Table 8.3, can be shown.

Velocity can be shown for the smoke detector for duct symbol shown in Table 8.3.

For the gas detector symbol shown in Table 8.3, the drawing should show the type of gas or gases being monitored. The drawing should indicate the lower explosive limit (LEL) and/or the upper explosive limit (UEL) of gas or gases.

A.9.1.1 The purpose of this chapter is to provide uniformity in the use of fire safety and related symbols in the preparation of pre-incident planning sketches.

The symbols in this chapter are provided to assist fire service or emergency response personnel who are responsible for preparing and using pre-incident planning sketches.

A.9.1.2 Triangle symbols are used for access features, assessment features, ventilation features, and utility shutoffs and can point at a specific location or direction. Diamond symbols identify a specific location by touching a wall. Circle symbols are used for all piping system components, such as valves, since most pipes are round.

Square symbols are used for room designations, as they represent most rooms having four sides.

A.9.2 For Section 9.2 through Section 9.5, other features to complete the pre-incident planning sketch can be used as appropriate.

A.9.6 Figure A.9.6 shows an example of hazardous identification.

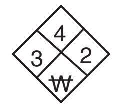

FIGURE A.9.6 Example of Hazardous Identification.

A.11.2.2 It is advisable to show the whole building floor plan with all exits, when possible.

A.11.3 See Figure A.11.3.

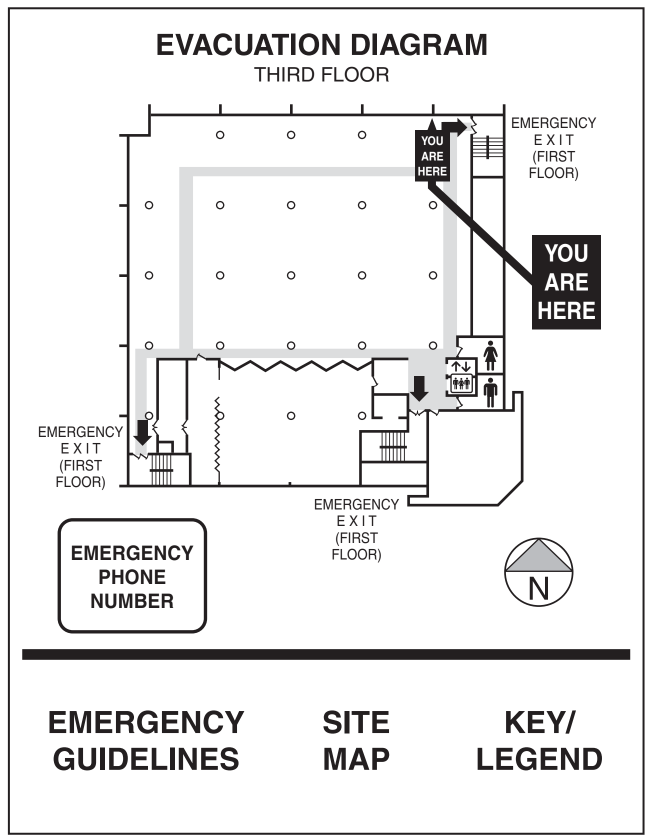

FIGURE A.11.3 Example of Proper Orientation.

Annex B Additional Explanatory Information on Chapters 1 Through 6

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

B.1 Reserved.

B.2 Reserved.

B.3 Additional Explanatory Information on Chapter 4.

B.3.1 Symbol Testing. Two or more versions of a symbol were developed for the referents listed in Chapter 4. The effectiveness of each of these symbols was evaluated by testing its meaningfulness (i.e., understandability) with groups of different participants. On the basis of these results, a symbol was selected for each referent. In some cases, the symbols were refined graphically to incorporate modifications suggested by the test results. Symbol development and refinement included the efforts of research psychologists, graphic designers, safety engineers, and fire professionals.

The life safety symbols were tested in the course of several different research projects during a 7-year period. These results are referenced in a series of publications by the National Bureau of Standards.

Although a variety of testing procedures were used to assess understandability, the basic method consisted of asking people either to write down short definitions or to pick the correct definition from a set of carefully selected choices. In several studies, data on symbol preference and rated effectiveness also were obtained.

For these testing efforts, one set of participants consisted of 222 industrial personnel and 78 students; another set consisted of 271 miners and mine personnel; and another set consisted of 94 paid volunteers. No major differences between participant groups were observed for the symbols selected for Chapter 4.

In addition to the studies of understandability, a detailed assessment was made of exit symbol visibility. This study used a laboratory optical viewing system to present a set of exit symbols included in a much larger set (108) of safety and information symbols. Three viewing conditions that simulated smoke were used (luminance of 0.085, 0.060, and 0.032 candela/m^2). Forty-two participants were familiarized with a randomly selected set of exit symbols to identify the separate effects of understandability and visibility. The symbol given in Chapter 4 was the symbol that was most frequently identified correctly under all three viewing conditions. In addition, the identification data were virtually the same whether participants had been familiarized with the symbol or not — suggesting that the symbol has high initial understandability. (This suggestion is reinforced by the high percentages of correct identification found in those studies that evaluated understandability.)

The results of the visibility testing program are important because an exit symbol must be both well understood and visible when under degraded viewing conditions such as smoke.

The goal of the overall testing program was to identify versions or elements of symbols for the selected referents that appeared to be most effective in communicating the intended message. It is recognized that further education and/or supplemental word messages can be useful in optimizing the effectiveness of these symbols with the general public. Nevertheless, the symbols selected have demonstrated good initial understandability. Symbols for the referents generally showed good understandability (better than 85 percent correct identification). Symbols that presented some understandability problems included "No Exit" and "Fire Alarm Call Point." The examples shown herein, however, represent the imagery that was best understood. It is hoped that use of these images will strengthen public recognition.

It also should be noted that the symbol for handicapped accessibility was not tested in this program. It is, however, in an existing ANSI standard, A117.1, *Specifications for Making Buildings and Facilities Accessible to and Usable by Physically Handicapped People,* and has achieved wide use and good recognition.

B.4 Additional Explanatory Information on Chapter 5.

B.4.1 Symbol Testing. At least two versions of a symbol were developed for each of the following referents:

(1) Fire department automatic sprinkler connection — siamese
(2) Fire department standpipe connection
(3) Fire department combined automatic sprinkler/standpipe connection
(4) Fire hydrant (all types)
(5) Automatic sprinkler control valve
(6) Electric panel or electric shutoff

The following referents are discussed in this section:

(1) Gas shutoff valve
(2) Fire-fighting hose or standpipe outlet
(3) Fire extinguisher
(4) Directional arrow
(5) Diagonal directional arrow

Subsequently, the effectiveness of the symbols was evaluated by testing their meaningfulness to groups of fire professionals; the procedures are outlined in this section. On the basis of the test results, a symbol was selected for each referent. This set of symbols was further refined graphically, incorporating modifications suggested by the test results. Symbol development and refinement through a Subcommittee on Visual Alerting Symbols included the efforts of fire professionals, graphic artists and designers, research psychologists, and safety engineers.

Symbols for gas shutoff valve, fire-fighting hose or standpipe outlet, fire extinguisher, directional arrow, and diagonal directional arrow were adapted from International Organization for Standardization (ISO) publications. The fire extinguisher symbol was included in the test procedure. Although the standpipe outlet symbol was not tested in isolation, it was incorporated as an element in two of the tested symbols (fire department standpipe connection and fire department combined automatic sprinkler/standpipe connection).

Participants in the test program included fire professionals attending a national convention or local (Maryland) training classes and totaled 86 participants. The test procedure involved two phases. In the first phase, the participants were shown one symbol at a time, in slide form, and were asked to write down a short definition of what they thought each symbol meant. In the second phase, two symbolic versions of each referent were shown together, and their intended meaning was provided; the participants indicated which version (if either) of each pair they felt better conveyed the meaning. They also were asked to give the reason for their preference and were free to offer any suggestions for improvement.

The goal of the testing program was to identify versions or elements of symbols for the selected referents that were most effective in visually alerting fire fighters. It is recognized that education might be required to optimize the effectiveness of the symbols for fire fighters. Nevertheless, it is important to select symbols that initially are meaningful. Symbols for seven of the nine referents tested showed good recognizability (85 to 100 percent) and no serious confusion with other possible meanings. However, for two referents — wall hydrant and gas control valve — recognition was poor, and confusion was common for both symbolic versions of each message. Therefore, no symbol for these two referents is presented in this standard. Graphic improvements and alternative conceptions are being sought. (A symbol for a gas shutoff valve was accepted for the 1991 edition of NFPA 170.)

B.4.2 The NFPA Committee on Fire Safety Symbols was able to identify a set of shapes for symbols to be used to direct responding fire fighters.

B.5 Additional Explanatory Information on Chapter 6.

B.5.1 Symbol Selection Procedure. See Figure B.5.1 for an example of the procedures involved in selecting fire safety symbols.

B.5.2 Discussion of Basic Symbols.

B.5.2.1 Symbol Testing. Inevitably, when a new standard is introduced to a field in which standardized symbols are not established and everyone is acting independently, controversy looms over the effort as to which (whose) alleged "standard" should be used. Such controversy can be met only with a national logic for meeting the standardization task. Such logic was used in developing former NFPA 172 now incorporated into Chapter 6.

B.5.2.2 This symbology effort ultimately employed the following steps:

(1) Identify problem. Is a standard for fire protection symbols needed?
(2) Identify referents. What devices should be symbolized? Consider applicability to fire protection and frequency of use.
(3) Identify symbols' availability. What symbols exist, and how widely are they used for fire protection and other disciplines?
(4) Develop a system of symbol selection. Can a system be identified so that referents and symbols can be rationally selected or developed? *(See B.5.1.)*
(5) Can a scheme of basic shapes be utilized in developing symbol sets for categories of referents?
(6) Adhere to the scheme. Make exceptions only where an overwhelming level of usage makes changes unreasonable.
(7) Avoid conflicts. Are there other practices and/or standards with which the proposed standard might be in conflict?

B.5.2.3 To accomplish step B.5.2.2(5), two factors had to be considered. First, there is very little agreement on symbols throughout North America. For the most part, various industry segments disagree on symbols and even on basic shapes. Second, the ISO Committee on Fire Protection Symbols for Use on Drawings completed most of its work on this subject before 1980 and proposed a set of basic symbol shapes.

B.5.2.4 With the two foregoing considerations, the NFPA Committee on Fire Safety Symbols was able to develop a set of basic shapes for symbols to be used on fire protection drawings. The basic shapes shown in Table B.5.2.4 were selected by uniting the ISO-proposed basic shapes and, where existent, the North American common practice. Thus, the collection of shapes (menu) represents a compromise with the sole major objective of developing a symbols standard aimed at a common language to improve future communication among users of fire protection drawings worldwide.

B.5.2.5 The collection of basic shapes in Table B.5.2.4 is broken down into a major classification of symbol elements and a supplementary set of symbol elements that can be used singly or in combination with other symbol elements. These basic symbol shapes and relative sizes are not exclusive of all the shapes and sizes that were used in developing former NFPA 172 (now incorporated into Chapter 6). They are a guide that was used in developing the family scheme.

It is recognized that the former NFPA 172 did not include all the fire safety symbols that can be required on architectural and engineering drawings. Table B.5.2.4 can therefore be used as a basis for future development of Chapter 6 or for the design of specialized symbols by the draftsperson.

Symbol elements have definite meanings and therefore should always be represented at the same relative size when used in different symbols.

B.5.2.6 The NFPA Committee on Fire Safety Symbols was able to identify a set of shapes for symbols to be used on fire protection drawings and diagrams *(see Table B.5.2.4)*. The shapes were selected through a reconciliation of the symbols presented in the former NFPA 172 (now incorporated into Chapter 6), the general shapes being drafted by the ISO, and, where existent, the common practice in North America. Thus, the family of shapes represents a compromise, with the major objective of developing a common language to improve future communication among users of fire protection diagrams worldwide.

B.5.3 Use of Color Coding.

B.5.3.1 General. The use of color coding to indicate various types of building construction is recommended and can be justified. Where used, color coding should be in conformity with this annex to maximize communication. Where color coding is not used, it is necessary to rely on printed detail.

B.5.3.2 Table B.5.3.2 presents a recommended system for color coding.

Table B.5.3.2 Color Coding of Construction Types

Construction Type*	Color
Fire resistive (Type I)	Light brown
Noncombustible/limited combustible (Type II)	Gray (brown border if masonry walls)
Heavy timber and ordinary (Type III and IV)	Pink
Wood frame (Type V)	Yellow

*See NFPA 220.

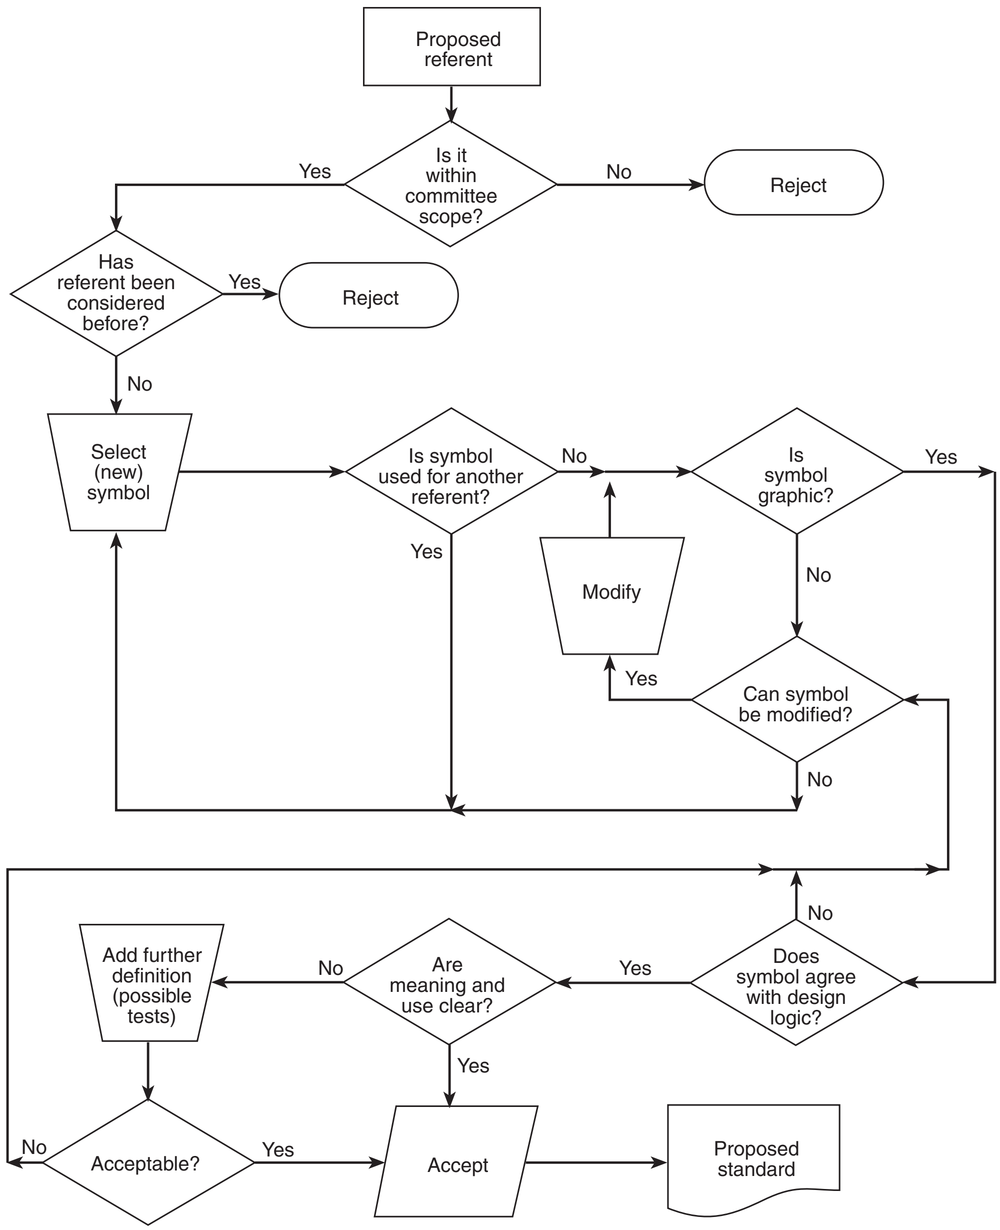

FIGURE B.5.1 Symbol Selection Procedure.

Table B.5.2.4 Basic Symbol Shapes and Relative Sizes

General Referent	Shape	Relative Size*	Comments
Major Elements			
Automatically actuating systems		4 mm (5/32 in.) diameter	Detection, extinguishment
Manually actuating systems		4 mm (5/32 in.) square	Manual alarm system
Control panel		4 mm × 8 mm (5/32 in. × 5/16 in.)	Supplementary element used to describe the panel
Portable fire extinguisher		5 mm (3/16 in.) sides	Supplementary element used to further describe the extinguisher
Fire-fighting equipment		6 mm (1/4 in.) sides	Supplementary element used to describe a specific device
Supplementary Elements			
Water system components		2 mm (3/32 in.) diameter	General shape, a circle; shading of element indicates wet device
Foam agent		5 mm (3/16 in.) diameter	
Dry chemical agent		2 mm (3/32 in.) square	
Gaseous agent		3 mm (1/8 in.) sides	
Nozzle			Used on pipe or other symbol
Pressure notation			Used with another symbol shape, such as a detector or a tank
Switch (electrical) or contact		2 mm (5/64 in.) diameter	
Valve		4 mm (5/32 in.) high	
Check valve		6 mm (1/4 in.) high (with arrow)	
Tamper detector		4 mm (5/32 in.) diameter	
Heat detector		1 mm (3/64 in.) diameter	
Flow detector		4 mm (5/32 in.) high	
1-hour fire rating		5 mm (3/16 in.) square	Used to indicate fire rating of walls in hours
Automatic detection and supervisory use devices		5 mm (3/16 in.) sides	Detection, supervisory

**Relative* is emphasized because it is not the intent here to specify actual dimensions. For comparisons, this column lists the suggested sizes of the symbols presented here.

Annex C Emergency Responder Map

This annex is not a part of the requirements of this NFPA document but is intended for informational purposes only.

C.1 Emergency Responder Plan. The plan shown in Figure C.1(a) and Figure C.1(b) provides emergency responders an example of maps showing the interior and exterior locations of the building using the symbols from Table 5.2 and information from Chapter 9. See Figure C.1(a) and Figure C.1(b).

NFPA® 204

Standard for

Smoke and Heat Venting

2015 Edition

This edition of NFPA 204, *Standard for Smoke and Heat Venting*, was prepared by the Technical Committee on Smoke Management Systems. It was issued by the Standards Council on November 11, 2014, with an effective date of December 1, 2014, and supersedes all previous editions.

This edition of NFPA 204 was approved as an American National Standard on December 1, 2014.

Origin and Development of NFPA 204

This project was initiated in 1956 when the NFPA Board of Directors referred the subject to the Committee on Building Construction. A tentative guide was submitted to NFPA in 1958. Revised and tentatively adopted in 1959 and again in 1960, the guide was officially adopted in 1961. In 1968, a revised edition was adopted that included a new section, Inspection and Maintenance.

In 1975, a reconfirmation action failed as concerns over use of the guide in conjunction with automatic sprinklered buildings surfaced. Because of this controversy, work on a revision to the guide continued at a slow pace.

The Technical Committee and Subcommittee members agreed that the state of the art had progressed sufficiently to develop improved technology-based criteria for design of venting; therefore, the 1982 edition of the document represented a major advance in engineered smoke and heating venting, although reservations over vent and sprinkler applications still existed.

At the time the guide was formulated, the current venting theory was considered unwieldy for this format; consequently, the more adaptable theory as described herein was adopted. Appreciation must be extended to Dr. Gunnar Heskestad at the Factory Mutual Research Corporation (now FM Global) for his major contribution to the theory applied in this standard, which is detailed in Annex B.

The 1985 edition again revised Chapter 6 on the subject of venting in sprinklered buildings. Test data from work done at the Illinois Institute of Technology Research, which had been submitted to the Committee as part of a public proposal, did not permit consensus to be developed on whether sprinkler control was impaired or enhanced by the presence of automatic roof vents of typical spacing and area. The revised wording of Chapter 6 encouraged the designer to use the available tools and data referenced in the document while the use of automatic venting in sprinklered buildings was under review.

The 1991 edition made minor changes to Chapter 6 to acknowledge that a design basis existed for using sprinklers and automatic heat venting together but that such had not received wide recognition.

The 1998 edition represented a complete revision of the guide. The rewrite deleted the previous tables that listed vent areas and incorporated engineering equations and referenced computer models, such as LAVENT and DETACT, to provide the designer with the necessary tools to develop vent designs based on performance objectives. This rewrite was based extensively on state-of-the-art technology published in the references. In many cases, the authors of these references participated in the task group's rewrite efforts.

The 2002 edition of NFPA 204 was converted from a guide to a standard, thus implementing mandatory requirements and updated language. The document was also updated to meet Manual of Style for NFPA Technical Committee Documents requirements.

NFPA and National Fire Protection Association are registered trademarks of the National Fire Protection Association, Quincy, Massachusetts 02169.

The 2007 edition included a number of technical changes. New provisions on air entrainment into the fire plume, the effect of wind on the location of air vents, sizing of air paths, air velocity limitations, and plugholing were provided. Information on the use of vents as air inlets and a better description of the smoke layer interface were added. Revisions with regard to how heat release rates, discharge coefficients, exhaust rates, and the number of exhaust inlets are to be determined were incorporated. Reference to international standards on vents, mechanical smoke extract, and draft curtains, as well as updated annex text on recent research efforts, were provided.

The 2012 edition was updated to include additional requirements and annex material for venting in sprinklered buildings.

The 2015 edition includes revised provisions on draft curtains. These requirements create consistency with NFPA 92.

Chapter 1 Administration

1.1 Scope.

1.1.1* This standard shall apply to the design of venting systems for the emergency venting of products of combustion from fires in buildings. The provisions of Chapters 4 through 10 shall apply to the design of venting systems for the emergency venting of products of combustion from fires in nonsprinklered, single-story buildings using both hand calculations and computer-based solution methods as provided in Chapter 9. Chapter 11 shall apply to venting in sprinklered buildings.

1.1.2* This standard shall not specify under which conditions venting is to be provided or required.

1.1.3 Where a conflict exists between a general requirement and a specific requirement, the specific requirement shall be applicable.

1.2 Purpose. (Reserved)

1.3 Application.

1.3.1* This standard shall not apply to ventilation within a building designed for regulation of environmental air for personnel comfort, to regulation of commercial cooking operations, to regulation of odor or humidity in toilet and bathing facilities, to regulation of cooling of production equipment, or to venting for explosion pressure relief.

1.3.2 This standard shall apply to building construction of all types.

1.3.3 This standard shall apply to venting fires in building spaces with ceiling heights that permit the design fire plume and smoke layer to develop.

1.3.4* This standard shall apply to situations in which the hot smoke layer does not enhance the burning rate of the fuel array. Vent designs developed with this standard shall not be valid for those time intervals where smoke layer temperatures exceed 600°C (1112°F).

1.3.5* This standard shall not be valid for fires having heat release rates greater than $Q_{feasible}$ as determined in accordance with the following equation:

$$Q_{feasible} = 12{,}000\left(z_s\right)^{5/2} \qquad \textbf{[1.3.5]}$$

where:

$Q_{feasible}$ = feasible fire heat release rate (kW)
z_s = height of the smoke layer boundary above the fire base (m)

1.3.6* The engineering equations or computer-based models incorporated into this standard shall be used to calculate the time duration that the smoke layer boundary is maintained at or above the design elevation in a curtained area, relative to the design interval time.

1.4 Retroactivity.

1.4.1 The provisions of this standard shall not be required to be applied retroactively.

1.4.2 Where a system is being altered, extended, or renovated, the requirements of this standard shall apply only to the work being undertaken.

1.5 Equivalency. Nothing in this standard is intended to prevent the use of systems, methods, or devices of equivalent or superior quality, strength, fire resistance, effectiveness, durability, and safety over those prescribed by this standard. Technical documentation shall be submitted to the authority having jurisdiction to demonstrate equivalency. The system, method, or device shall be approved for the intended purpose by the authority having jurisdiction.

1.6 Units and Formulas. The following symbols define the variables in the equations used throughout the body of this standard:

A = area (of burning surface)
A_i = inlet area for fresh air, below design level of smoke layer boundary
A_v = total vent area of all vents in a curtained area
α = thermal diffusivity, $k/\rho c$
α_g = fire growth coefficient
γ = exhaust location factor (dimensionless)
c_p = specific heat
$C_{d,v}$ = vent discharge coefficient
$C_{d,i}$ = inlet discharge coefficient
d = smoke layer depth
d_c = depth of draft curtain
D = base diameter of the fire
g = acceleration of gravity
H = ceiling height above base of fire
h_c = heat of combustion
h_g = heat of gasification

K = fraction of adiabatic temperature rise
k = thermal conductivity
$k_e\beta$ = constant used in Equation E.5.1
$k\rho c$ = thermal inertia
l = thickness
L = mean flame height above the base of the fire
L_f = flame length, measured from leading edge of burning region
L_v = length of vent opening in the longer direction
$\dot{m}$ = mass burning rate
$\dot{m}''$ = mass burning rate per unit area
$\dot{m}''_\infty$ = mass burning rate per unit area for an infinite diameter pool
$\dot{m}_v$ = mass flow rate through vent
$\dot{m}_p$ = mass flow rate in the plume
$\dot{m}_{pL}$ = mass flow rate in the plume at mean flame height (L)
$\dot{q}''_i$ = incident heat flux per unit area
Q = total heat release rate
Q'' = total heat release rate per unit floor area
Q_c = convective heat release rate = $\chi_c Q$
$Q_{feasible}$ = feasible fire heat release rate (kW)
r = radius from fire axis
RTI = response time index $\tau u^{1/2}$
τ = time constant of heat-responsive element for convective heating
ρ = density
ρ_o = ambient air density
S = center to center spacing of vents
t = time
t_d = time to detector activation
t_g = growth time of fire
t_{ig} = time to ignition
t_r = design interval time
t_{sa} = time to sprinkler activation
t_{vo} = time to vent opening
ΔT = gas temperature rise (from ambient) at detector site
ΔT_a = adiabatic temperature rise
ΔT_e = temperature rise (from ambient) of heat-responsive element
T = smoke layer temperature (K)
T_o = ambient air temperature
T_{ig} = ignition temperature
T_s = surface temperature
u = gas velocity at detector site
W_{min} = lateral fire spread by radiation
W_s = largest horizontal dimension of fire
W_v = width of vent opening in the shorter direction
V = flame spread velocity
χ_c = convective fraction of total heat release rate (fraction carried as heat in plume above flames) where χ_c is a convective-heat fraction between 0.6 and 0.7
χ_r = radiant fraction of total heat release rate
y = elevation of smoke layer boundary
y_{ceil} = elevation of ceiling
y_{curt} = elevation of bottom of draft curtain
y_{fire} = elevation of the base of the fire above the floor
z_s = height of the smoke layer boundary above base of fire
z_{si} = height of the smoke layer interface above the base of the fire
z_o = height of virtual origin above base of fire (below base of fire, if negative)

Chapter 3 Definitions

3.1 General. The definitions contained in this chapter shall apply to the terms used in this standard. Where terms are not defined in this chapter or within another chapter, they shall be defined using their ordinarily accepted meanings within the context in which they are used. *Merriam-Webster's Collegiate Dictionary,* 11th edition, shall be the source for the ordinarily accepted meaning.

3.2 NFPA Official Definitions.

3.2.1* Approved. Acceptable to the authority having jurisdiction.

3.2.2* Authority Having Jurisdiction (AHJ). An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

3.2.3 Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

3.2.4* Listed. Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

3.2.5 Shall. Indicates a mandatory requirement.

3.2.6 Should. Indicates a recommendation or that which is advised but not required.

3.3 General Definitions.

3.3.1 Ceiling Jet. A flow of smoke under the ceiling, extending radially from the point of fire plume impingement on the ceiling.

3.3.2 Clear (Air) Layer. The zone within a building containing air that has not been contaminated by the smoke produced from a fire in the building, and that is located between the floor and the smoke layer boundary.

3.3.3* Clear Layer Interface. The boundary between a smoke layer and smoke-free air.

3.3.4 Continuously Growing Fires. Fires that, if unchecked, will continue to grow over the design interval time.

3.3.5 Curtained Area. An area of a building that has its perimeter delineated by draft curtains, full height partitions, exterior walls, or any combinations thereof.

3.3.6 Design Depth of the Smoke Layer. The difference between the height of the ceiling and the minimum height of the smoke layer boundary above the finished floor level that meets design objectives.

3.3.7 Design Fire. As used in this standard, the time-rate heat release history selected as the input for the calculations prescribed herein.

3.3.8 Design Interval Time. The duration of time for which a design objective is to be met, measured from the time of detector activation.

3.3.9* Draft Curtain. A fixed or deployable barrier that protrudes downward from the ceiling to channel, contain, or prevent the migration of smoke.

3.3.10* Effective Ignition. The time at which a *t*-squared design fire starts.

3.3.11 Fuel Array. A collection and arrangement of materials that can support combustion.

3.3.12 Heat Detector. A fire detector that detects either abnormally high temperature or rate of temperature rise, or both. [**72,** 2013]

3.3.13 Limited-Growth Fires. Fires that are not expected to grow beyond a predictable maximum heat release rate.

3.3.14 Mechanical Smoke Exhaust System. A dedicated or shared-duty fan system designed and suitable for the removal of heat and smoke.

3.3.15 Plastics.

3.3.16 Plugholing. The condition where air from below the smoke layer is pulled through the smoke layer into the smoke exhaust due to a high exhaust rate. [**92,** 2015]

3.3.17 Smoke. The airborne solid and liquid particulates and gases evolved when a material undergoes pyrolysis or combustion, together with the quantity of air that is entrained or otherwise mixed into the mass. [**318,** 2012]

3.3.18* Smoke Layer. The accumulated thickness of smoke below a physical or thermal barrier. [**92,** 2015]

3.3.19* Smoke Layer Boundary. An effective boundary centered in a transition zone between the dense portion of the smoke layer and the first indication of smoke.

3.3.20 Vent. As used in this standard, a device or construction that, when activated, is an opening directly to the exterior at or near the roof level of a building that relies on the buoyant forces created by a fire to exhaust smoke and heat.

3.3.21 Vent System. A system used for the removal of smoke and heat from a fire that utilizes manually or automatically operated heat and smoke vents at roof level and that exhausts smoke from a reservoir bounded by exterior walls, interior walls, or draft curtains to achieve the design rate of smoke mass flow through the vents, and that includes a provision for makeup air.

Chapter 4 Fundamentals

4.1* Design Objectives. The design objectives to be achieved over the design interval time by a vent system design during a design fire or design fires shall include the following:

(1) The minimum allowable smoke layer boundary height
(2) The maximum allowable smoke layer temperature

4.2* Design Basis. A design for a given building and its combustible contents and their distribution shall comprise selecting a design basis (limited-growth versus continuous-growth fire) and establishing the following parameters:

(1) Layout of curtained areas
(2) A draft curtain depth
(3) Type detector and specific characteristics
(4) Detector spacing
(5) A design interval time, t_r, following detection for maintaining a clear layer (for continuous-growth fires)
(6) Total vent area per curtained area
(7) Distribution of individual vents
(8) An air inlet area

4.3 Determination of Contents Hazard.

4.3.1 The determination of contents hazard shall take into account the fuel loading and the rate of heat release anticipated from the combustible materials or flammable liquids contained within the building.

4.3.2 The heat release rate of the design fire shall be quantified in accordance with Chapter 8.

4.4 Venting.

4.4.1 Design Objectives. In order to satisfy design objectives, a vent system shall be designed to slow, stop, or reverse the descent of a smoke layer produced by fire in a building, by exhausting smoke to the exterior.

4.4.2* Vent System Designs and Smoke Production.

4.4.2.1 Vent systems shall be designed in accordance with this standard by calculating the vent area required to achieve a mass rate of flow through the vents that equals the mass rate of smoke production.

4.4.2.2 Vent system designs shall limit the descent of the smoke layer to the design elevation of the smoke layer boundary.

4.4.2.3 Alternative vent system designs shall be permitted to be developed in accordance with this standard by calculating the vent area required to achieve a mass rate of flow through the vents that is less than the mass rate of smoke production, such that the descent of the smoke layer is slowed to meet the design objectives.

4.4.3* Vent Mass Flow. Vent system designs shall be computed on the basis that the mass flow rate through a vent is determined primarily by buoyancy pressure.

4.5 Smoke Production.

4.5.1* Base of the Fire. For the purposes of the equations in this standard, the base of the fire shall be at the bottom of the burning zone.

4.5.2* Fire Size. Burning and entrainment rates of possible fire scenarios shall be considered before establishing the conditions of the design fire.

4.5.3* Entrainment.

4.5.3.1 The entrainment formulas specified in this standard shall be applied only to a single fire origin.

4.5.3.2* Virtual Origin. Predicted plume mass flow above the top of the flame shall take into account the virtual origin, z_o, of the fire as determined in 9.2.3.2.

4.6 Vent Flows.

4.6.1* Buoyancy and Vent Flow.

4.6.1.1 Flow through a vent shall be calculated on the basis of buoyancy pressure difference, assuming that no pressure is contributed by the expansion of gases.

4.6.1.2* Beneficial wind effects shall not be taken into account when calculating vent areas.

4.6.1.3 Air inlets and vents shall be located to avoid adverse wind effects.

4.6.2* Inlet Air.

4.6.2.1 Predicted vent flows shall take into account the area of inlet air openings.

4.6.2.2 Inlet air shall be introduced below the smoke layer boundary.

4.6.2.3 Wall and ceiling leakage above the smoke layer boundary in the curtained area shall not be included in vent flow calculations. *(See Chapter 6 for information on air inlets.)*

Chapter 5 Vents

5.1* Listed Vents. Normally closed vents shall be listed and labeled in accordance with ANSI/UL 793, *Standard for Automatically Operated Roof Vents for Smoke and Heat*; FM 4430, *Approval Standard for Heat and Smoke Vents*; or other approved, nationally recognized standards.

5.2 Vent Design Constraints.

5.2.1* The means of vent actuation shall be selected with regard to the full range of expected ambient conditions.

5.2.2* Vents shall consist of a single unit (vent), in which the entire unit (vent) opens fully with the activation of a single detector, or multiple units (vents) in rows or arrays (ganged vents) in which the units (vents) open simultaneously with the activation of a single heat detector, a fusible link, a smoke detector, a sprinkler waterflow switch, or other means of detection to satisfy the venting requirements for a specific hazard.

5.2.3* Where the hazard is localized, vents shall open directly above such hazard.

5.2.4 Vents, and their supporting structure and means of actuation, shall be designed so that they can be inspected visually after installation.

5.3 Methods of Operation.

5.3.1* Normally, closed vents shall be designed to open automatically in a fire to meet design objectives or to comply with performance objectives or requirements.

5.3.2* Vents, other than thermoplastic drop-out vents, shall be designed to fail in the open position such that failure of a vent-operating component results in an open vent.

5.3.3 Vents shall be opened using gravity or other approved opening force.

5.3.4 The opening mechanism shall not be prevented from opening the vent by snow, roof debris, or internal projections.

5.3.5* All vents shall be designed to open by manual means. Means of opening shall be either internal or external, as approved by the authority having jurisdiction.

5.3.6 Vents designed for remote operation shall utilize approved fusible links and shall also be capable of actuation by an electric power source, heat-responsive device, or other approved means.

5.3.7 Vents designed to activate by smoke detection, sprinkler waterflow, or other activation methods external to the vent shall be approved in accordance with Section 5.1.

5.4 Dimensions and Spacing of Vents.

5.4.1 The dimensions and spacing of vents shall meet the requirements of 5.4.1.1 and 5.4.1.2 to avoid plugholing.

5.4.1.1 The area of a unit vent shall not exceed $2d^2$, where d is the design depth of the smoke layer.

5.4.1.2* For vents with $L_v/W_v > 2$, the width, W_v, shall not exceed the design depth of the smoke layer, d.

5.4.2* In plan view, the center-to-center spacing of vents in a rectangular matrix, S, as shown in Figure 5.4.2(a), within a curtained area shall not exceed $4H$, where H is the ceiling height as shown in Figure 5.4.2(b), parts (a) through (d).

5.4.3* The spacing of vents, in plan view, shall be such that the horizontal distance from any point on a wall or draft curtain to the center of the nearest vent, within a curtained area, does not exceed $2.8H$ as indicated in Figure 5.4.3.

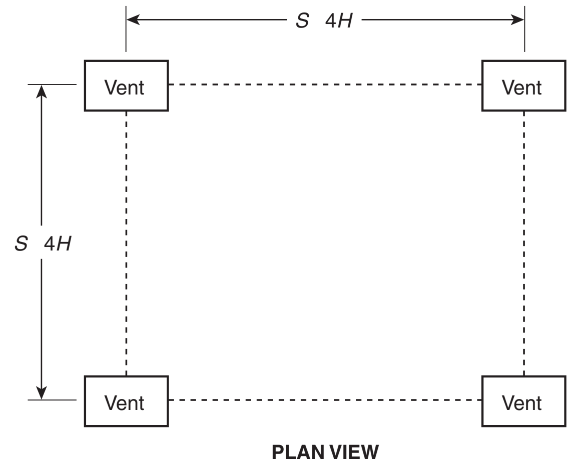

FIGURE 5.4.2(a) Vent Spacing in Rectangular Matrix (plan view).

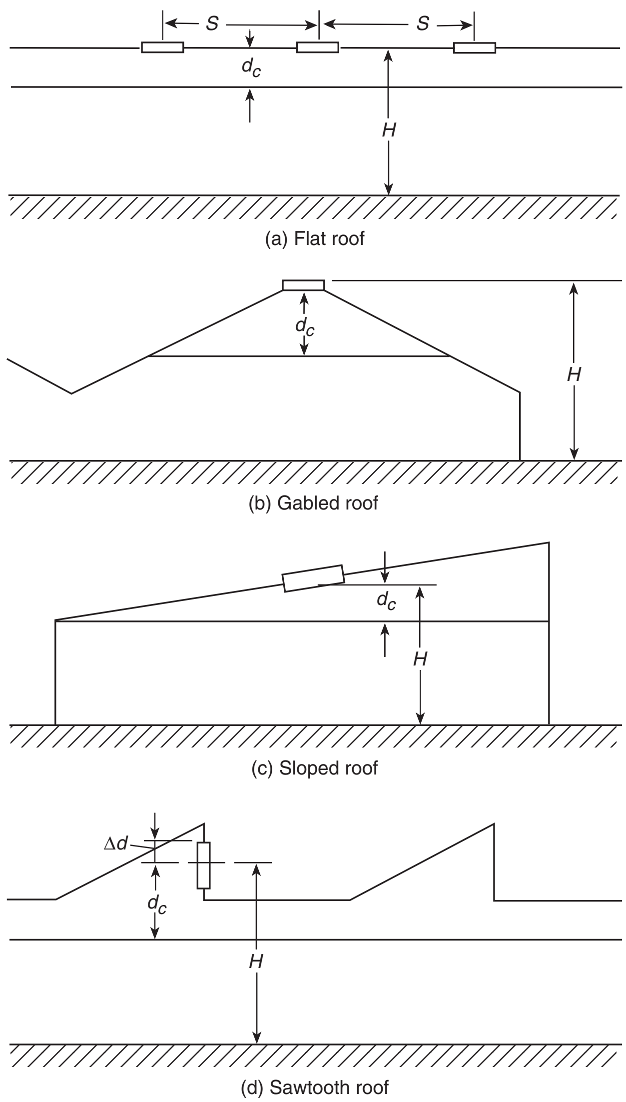

FIGURE 5.4.2(b) Measurement of Ceiling Height *(H)* and Curtain Board Depth *(d_c)*.

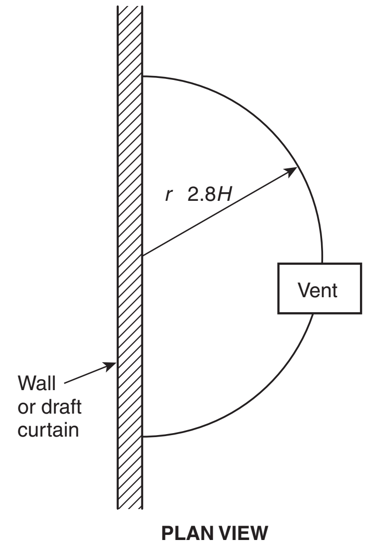

FIGURE 5.4.3 Vent Location near a Wall or Draft Curtain (plan view).

5.4.4 The total vent area per curtained area shall be sized to meet the design objectives and the performance objectives relative to the design fire, determined in accordance with Chapter 8.

5.5 Mechanical Smoke Exhaust Systems. Mechanical smoke exhaust systems shall be designed in accordance with Chapter 10.

Chapter 6 Air Inlets

6.1* General. Air inlets shall be provided for supplying makeup air for vent systems.

6.2 Construction. Air inlets consisting of louvers, doors, dampers, windows, shutters, or other approved openings shall be designed and constructed to provide passage of outdoor air into the building.

6.3* Location. Air inlets shall be installed as indicated in 6.3.1 or 6.3.2.

6.3.1 Air inlets shall be installed in external walls of the building below the height of the design level of the smoke layer boundary and shall be clearly identified or marked as air inlets.

6.3.2 In larger buildings where there is more than one curtained area, air inlets shall be permitted to be provided by vents in other nonadjacent curtained areas.

6.4 Installation.

6.4.1 Materials of construction and methods of installation for air inlets shall resist expected extremes of temperature, wind, building movement, rain, hail, snow, ice, sunlight, corrosive environment, internal and external dust, dirt, and debris.

6.4.2 The means of air inlet actuation shall be selected with regard to the full range of expected ambient conditions.

6.4.3 To satisfy the vent system requirements, air inlets shall consist of one of the following:

(1) A single unit (air inlet) in which the entire unit (air inlet) opens fully with the activation of a single detector
(2) Multiple units (air inlets) in rows or arrays (ganged air inlets) in which the units (air inlets) open simultaneously with the activation of a single heat detector, a fusible link, a smoke detector, a sprinkler waterflow switch, or other means of detection to satisfy the vent system requirements

6.4.4 Air inlets and their supporting structures and means of actuation shall be designed such that they can be inspected visually after installation.

6.5 Methods of Operation.

6.5.1 Air inlets shall be either constantly open or automatically placed in the open position after a fire is detected.

6.5.2 Air inlets shall be designed to open in a fire to meet design objectives or to comply with performance objectives or requirements.

6.5.3 Air inlets shall be designed to fail in the open position such that failure of an air inlet–operating component results in an open air inlet.

6.5.4 Air inlets shall be opened using an approved means as the opening force.

6.5.5 Air inlet opening mechanisms shall not be prevented from opening the air inlet by snow, debris, or internal projections.

6.5.6 Operating mechanisms for air inlets shall be jam-proof, corrosion-resistant, dust-resistant, and resistant to pressure differences arising from applicable positive or negative loading resulting from environmental conditions, process operations, overhead doors, or traffic vibrations.

6.5.7 Air inlets designed for remote operation shall be activated by approved devices and shall be capable of actuation by an electrical power source, heat-responsive device, or other approved means.

6.6 Dimensions and Spacing of Air Inlets.

6.6.1 The total inlet area per curtained area shall be sized to meet the design objectives and the performance objectives or requirements specified relative to the design fire, determined in accordance with Chapter 8.

6.6.2 One inlet area shall be permitted to serve more than one curtained area.

6.6.3* The air velocity at the plume shall not exceed 1 m/s (3.28 ft/s).

6.7 Air Paths. Air paths from an air inlet opening to the curtained area where smoke is being exhausted shall be at least three times the size of the air inlet opening.

Chapter 7 Draft Curtains

7.1* General. Where the spacing between walls exceeds the limits in Section 7.4, draft curtains shall be provided.

7.2* Construction.

7.2.1 Draft curtains shall remain in place and shall confine smoke when exposed to the maximum predicted temperature for the design interval time, assuming a design fire in close proximity to the draft curtain.

7.3 Location and Depth.

7.3.1* Draft curtains shall extend vertically downward from the ceiling the minimum distance required so that the value of d_c, as shown in Figure 5.4.2(a), is a minimum of 20 percent of the ceiling height, H, measured as follows:

(1) For flat roofs and sawtooth roofs with flat ceiling areas, from the ceiling to the floor
(2) For sloped roofs, from the center of the vent to the floor

7.3.2 Where there are differing vent heights, H, each vent shall be calculated individually.

7.4 Spacing.

7.4.1* Neither the length nor the width of a curtained area shall exceed eight times the ceiling height.

7.4.2* Where draft curtains extend to a depth of less than 30 percent of the ceiling height, the distance between draft curtains shall be not less than one ceiling height.

Chapter 8 The Design Fire

8.1* General.

8.1.1 The design fire shall be selected from among a number of challenging candidate fires, consistent with the building and its intended use, considering all of the following factors that tend to increase the challenge:

(1) A low-level flame base (usually floor level)
(2) Increasing fire growth rate
(3) Increasing ultimate heat release rate in the design interval time

8.1.2 The candidate fire that produces a vent system design meeting the design objectives for all candidate fires shall be selected as the design fire.

8.2 Steady (Limited-Growth) Fires.

8.2.1 For steady fires, or fires that do not develop beyond a maximum size, the required vent area per curtained area shall be calculated based on the maximum calculated heat release rate (Q and Q_c), the associated distance from the fire base to the design elevation of the smoke layer boundary (z_s), and the predicted fire diameter (D).

8.2.2* Steady fires shall be permitted to include special-hazard fires and fires in occupancies with concentrations of combustibles separated by aisles of sufficient width to prevent the spread of fire by radiation beyond the initial fuel package or initial storage array.

8.2.3 The minimum aisle width required to prevent lateral fire spread by radiation, W_{min}, shall be calculated for radiant heat flux from a fire based on an ignition flux of 20 kW/m^2 (2.5 hp/ft^2) in accordance with the following equation:

$$W_{min} = 0.042 Q_{max}^{1/2} \quad \textbf{[8.2.3]}$$

where:
W_{min} = minimum aisle width required to prevent lateral fire spread by radiation (m)
Q_{max} = maximum anticipated heat release rate (kW)

8.2.4 The fire diameter, *D*, shall be the diameter of a circle having the same area as the floor area of the fuel concentration.

8.2.5 The heat release rate shall be the heat release rate per unit area times the floor area of the fuel concentration, using the maximum storage height above the fire base and associated heat release rate.

8.2.6* The heat release rate per unit area shall be determined by test or from published data acceptable to the AHJ.

8.3 Growing (Continuous-Growth) Fires.

8.3.1* For fuel configurations that have been tested, the fire growth shall be modeled to follow the test results acceptable to the AHJ. For other fuel configurations that have not been tested, a *t*-squared fire growth as shown in Figure 8.3.1 shall be used with a fire growth coefficient based on published data acceptable to the AHJ and in accordance with the following equation:

$$Q = 1055\left(\frac{t}{t_g}\right)^2 \quad \text{[8.3.1]}$$

where:
Q = heat release rate of fire (kW)
t = time from effective ignition following an incubation period (s)
t_g = time at which the fire exceeds an intermediate size of 1055 kW (s)

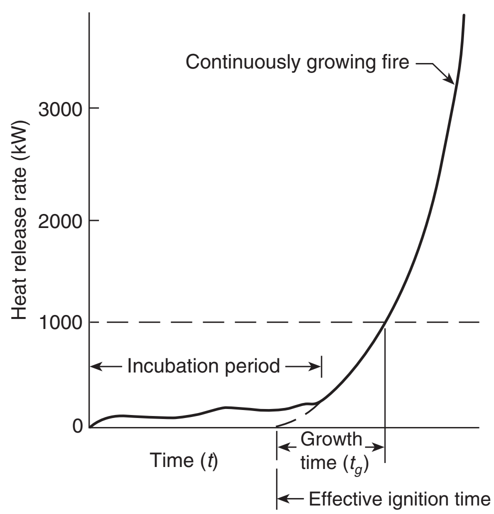

FIGURE 8.3.1 Conceptual Illustration of Continuous-Growth Fire.

8.3.2* A *t*-squared fire growth shall be permitted to be expressed in terms of a fire growth coefficient, α_g, in lieu of growth time, t_g, as follows:

$$Q = \alpha_g t^2 \quad \text{[8.3.2]}$$

where:
Q = heat release rate of fire (kW)
α_g = fire growth coefficient (kW/s^2)
t = time (s)

8.3.3 The instantaneous heat release rate per unit height of the storage array shall be considered to be constant, regardless of the storage height. Accordingly, for different storage heights, the growth time, t_g, shall be calculated as being inversely proportional to the square root of the storage height, and the fire growth coefficient, α_g, shall be calculated as being directly proportional to the storage height. *(See Section F.1.)*

8.3.4* The vent system shall maintain the smoke boundary layer above the design elevation from the time of effective ignition until the end of the design interval time, t_r, where t_r is measured from the time of detection, t_d.

8.3.5 The heat release rate at the end of the design interval time shall be calculated in accordance with the following equation:

$$Q = 1055\left(\frac{t_r + t_d}{t_g}\right)^2 \quad \text{[8.3.5]}$$

where:
Q = heat release rate (kW)
t_r = time at end of design interval (s)
t_d = time of detection (s)
t_g = time at which fire exceeds 1055 kW (s)

8.3.6 The end of the design interval time, t_r, shall be selected to correspond to the design objectives as determined for the specific project design.

8.3.7 The instantaneous diameter of the fire needed for the calculation of L and z_o shall be calculated from the instantaneous heat release rate, Q, and data on the heat release rate per unit floor area, Q'', where Q'' is proportional to storage height in accordance with the following equation:

$$D = \left(\frac{4Q}{\pi Q''}\right)^{1/2} \quad \text{[8.3.7]}$$

where:
D = instantaneous fire diameter (m)
Q = instantaneous heat release rate (kW)
Q'' = heat release rate per unit floor area (kW/m^2)

Chapter 9 Sizing Vents

9.1* General.

9.1.1* The design vent area in a curtained area shall equal the vent area required to meet the design objectives for the most challenging fire predicted for the combustibles within the curtained area.

9.1.2 Vent areas shall be determined using hand calculations in accordance with Section 9.2 or by use of a computer-based model in accordance with Section 9.3.

9.1.3 The design fire used in the evaluation of a proposed vent design in accordance with Section 9.1 shall be determined in accordance with Chapter 8.

9.1.4* Vent systems shall be designed specifically for the hazard of each curtained area in a building.

9.2 Hand Calculations.

9.2.1 Vent System Designs. Vent systems, other than those complying with Section 9.3, shall be sized and actuated to meet design objectives in accordance with Section 9.2.

9.2.2 Design Concepts.

9.2.2.1* Equilibrium shall be assumed as illustrated in Figure 9.2.2.1, where symbols are as defined in Section 1.6.

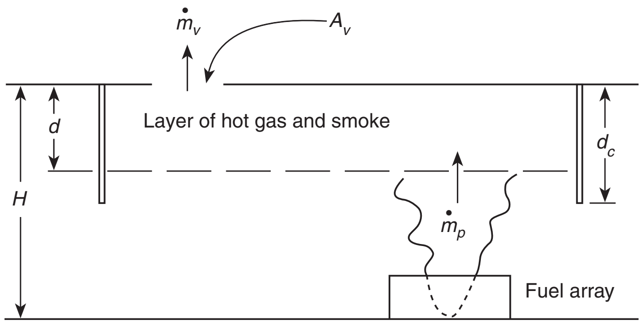

FIGURE 9.2.2.1 Schematic of Venting System.

9.2.2.2 The smoke layer boundary shall be at or above the bottom of the draft curtains.

9.2.2.3 At equilibrium, the mass flow rate into the smoke layer shall be equal to the mass flow rate out of the vent or vents ($\dot{m}_p = \dot{m}_v$).

9.2.3 Mass Flow Rate in Plume.

9.2.3.1* The mean flame height shall be calculated in accordance with the following equation:

$$L = -1.02D + 0.235\,Q^{2/5} \qquad \textbf{[9.2.3.1]}$$

where:
L = mean flame height above the base of the fire (m)
D = base diameter of fire (m)
Q = total heat release rate (kW)

9.2.3.2 The virtual origin, z_o, is the effective point source of the fire plume and shall be calculated in accordance with the following equation:

$$z_o = 0.083Q^{2/5} - 1.02D \qquad \textbf{[9.2.3.2]}$$

where:
z_o = virtual fire origin
Q = total heat release rate (kW)
D = base diameter of fire (m)

9.2.3.3 Smoke entrainment relationships shall be applicable to axisymmetric plumes.

9.2.3.4 For line-like fires where a long, narrow plume is created by a fuel or storage array, the smoke production calculated in accordance with this standard shall be applicable only if the height of the smoke layer boundary above the base of the fire (z_s) is greater than or equal to four times the largest horizontal dimension of the fire, W_s.

9.2.3.5 If z_s is smaller than $4W_s$, the smoke production rates calculated in accordance with this standard shall be increased by the factor $[4W_s/(z_s)]^{2/3}$.

9.2.3.6 When the mean flame height, L, is below the smoke layer boundary ($L < z_s$), the mass flow rate in the fire plume shall be calculated in accordance with the following equation:

$$\dot{m}_p = \left[0.071\,Q_c^{1/3}\left(z_s - z_o\right)^{5/3}\right]\left[1 + 0.027\,Q_c^{2/3}\left(z_s - z_o\right)^{-5/3}\right] \qquad \textbf{[9.2.3.6]}$$

where:
$\dot{m}_p$ = mass flow rate in the plume (kg/s)
Q_c = convective heat release rate = $0.7Q$ (kW)
z_s = height of the smoke layer boundary above the base of the fire (m)
z_o = height of virtual origin above the base of the fire (if below the base of the fire, z_o is negative) (m)

9.2.3.7 When the mean flame height (L) is equal to or above the smoke layer boundary ($L \geq z_s$), the mass flow rate shall be calculated in accordance with the following equation:

$$\dot{m}_p = \left(0.0056Q_c\right)\frac{z_s}{L} \qquad \textbf{[9.2.3.7]}$$

where:
$\dot{m}_p$ = mass flow rate in the plume (kg/s)
Q_c = convective heat release rate = $0.7Q$ (kW)
z_s = height above the base of the fire (m)
L = mean flame height (m)

9.2.3.8 The base of the fire shall be the lowest point of the fuel array.

9.2.4* Mass Flow Rate Through Vents.

9.2.4.1* The mass flow through the vent shall be calculated in accordance with the following equation:

$$\dot{m}_v = \frac{C_{d,v}A_v}{\sqrt{1 + \dfrac{C_{d,v}^2 A_v^2}{C_{d,i}^2 A_i^2}\left(\dfrac{T_o}{T}\right)}}\sqrt{\left(2\rho_o^2 gd\right)}\sqrt{\frac{T_o\left(T - T_o\right)}{T^2}} \qquad \textbf{[9.2.4.1]}$$

where:
$\dot{m}_v$ = mass flow through vent (kg/s)
$C_{d,v}$ = vent discharge coefficient
A_v = vent area (m^2)
ρ_o = ambient density (kg/m^3)
g = acceleration due to gravity (9.81 m/s^2)
d = smoke layer depth (m)
T_o = ambient temperature (K)
T = smoke layer temperature (K)
$C_{d,i}$ = inlet discharge coefficient
A_i = inlet area (m^2)

9.2.4.2* The discharge coefficients for the vents and inlets used shall be those provided by the vent or inlet manufacturer. If no data are available, the discharge coefficient shall be taken from Table 9.2.4.2 unless an analysis or data acceptable to the AHJ are provided by the designer to validate the use of an alternative value.

9.2.4.3 The smoke layer temperature, T, used in 9.2.4.1 shall be determined from the following equation:

$$T = T_o + \frac{KQ_c}{c_p \dot{m}_p} \qquad \textbf{[9.2.4.3]}$$

where:
T = smoke layer temperature (K)
T_o = ambient temperature (K)
K = fraction of convected energy contained in the smoke layer gases *(see 9.2.4.4)*
Q_c = convective heat release rate (kW)
c_p = specific heat of the smoke layer gases (kJ/kg-K)
$\dot{m}_p$ = plume mass flow rate (kg/s) *(see 9.2.3)*

Table 9.2.4.2 Default Discharge Coefficients for Vents and Inlets

Vent or Inlet Type	Discharge Coefficient [(*d*, *v*) and (*d*, *i*)]
Louvered with blades at 90 degrees to airflow	0.55
Flap type or door open at least 55 degrees	
Drop-out vent leaving clear opening	
Flap type or door open at least 30 degrees	0.35
Fixed weather louver with blades at 45 degrees	0.25

9.2.4.4 The value of K used in Equation 9.2.4.3 shall be 0.5, unless an analysis acceptable to the AHJ is provided by the designer to validate the use of an alternative value.

9.2.5 Required Vent Area and Inlet Area.

9.2.5.1 Vent Area. The required vent area shall be the minimum total area of all vents within a curtained area required to be open to prevent the smoke from descending below the design level of the smoke layer boundary when used in conjunction with the required inlet area.

9.2.5.2 Inlet Area. The required inlet area shall be the minimum total area of all inlets required to be open to prevent the smoke from descending below the design level of the smoke layer boundary when used in conjunction with the required vent area(s).

9.2.5.3 Area Calculation. The required vent area and inlet areas shall be calculated by equating the plume mass flow rate determined in 9.2.3 and the vent mass flow rates determined in 9.2.4.

9.2.5.4 Detection and Activation.

9.2.5.4.1* Detection, for the purpose of automatically actuating vents, shall be by one of the following methods:

(1) By either heat or smoke at the vent location
(2) By activation of fire protection systems
(3) By heat or smoke detectors installed on a regular matrix within the curtained area in accordance with *NFPA 72*
(4) By other approved means shown to meet design objectives

9.2.5.4.2 For calculating both the detection time, t_d, of the first detector to operate and the detection time, t_{vo}, of the detector controlling the actuation of the last vent to operate in a curtained area prior to the end of the design interval time, the location of the design fire shall be assumed to be the farthest distance possible from both the first and last detectors to operate the vents within the curtained area.

9.2.5.4.2.1* Detection times for heat detectors or fusible links shall be determined in accordance with *NFPA 72*.

9.2.5.4.3 Detection times for smoke detectors shall be determined as the time to reach a certain temperature rise, ΔT, at activation. In the case of continuous-growth, *t*-squared fires, gas temperatures shall be determined in accordance with the following equation, where ΔT is assumed to be 0 when the numerator of the first bracket is zero or negative:

$$\Delta T = \frac{3575}{t_g^{4/5} H^{3/5}} \left[\frac{t / \left(t_g^{2/5} H^{4/5} \right) - 0.442 \left(1 + r / H \right)}{1 + 1.65 r / H} \right]^{4/3} \quad \textbf{[9.2.5.4.3]}$$

where:
T = temperature (C)
t_g = fire growth time (s)
H = ceiling height above the base of the fire (m)
r = radius from fire axis (m)

9.2.5.4.3.1* The temperature rise for activation shall be based on dedicated tests, or the equivalent, for the combustibles associated with the occupancy and the detector model to be installed.

9.2.5.4.3.2 Where the data described in 9.2.5.4.3.1 are not available, a minimum temperature rise of 20°C (68°F) shall be used.

9.2.5.4.4 Detection Computer Programs.

9.2.5.4.4.1* As an alternate to the calculations specified in 9.2.5.4.2, DETACT-T2 shall be permitted to be used to calculate detection times in continuous-growth and *t*-squared fires.

9.2.5.4.4.2* As an alternative to the calculations specified in 9.2.5.4.2, DETACT-QS shall be permitted to be used to calculate detection times in fires of any fire growth history.

9.2.5.4.4.3 Other computer programs determined to calculate detection times reliably shall be permitted to be used when approved by the AHJ.

9.3 Models.

9.3.1 Vents, other than vent systems designed in accordance with Section 9.2, shall be sized and actuated to meet design objectives in accordance with Section 9.3.

9.3.2 The computer model LAVENT or other approved mathematical models shall be used to assess the effects of the design fire and to establish that a proposed vent system design meets design objectives. *(See Section F.2.)*

9.3.3 When models other than LAVENT are used, evidence shall be submitted to demonstrate efficacy of the model to evaluate the time-varying events of a fire and to calculate the effect of vent designs reliably in terms of the design objectives.

9.3.4 The design fire used in the evaluation of a proposed vent system design in accordance with Section 9.3 shall be determined in accordance with Chapter 8.

Chapter 10 Mechanical Smoke Exhaust Systems

10.1* General.

10.1.1* Mechanical smoke exhaust systems shall be permitted in lieu of the vent systems described in Chapter 9.

10.1.2 Mechanical smoke exhaust systems and vent systems shall not serve the same curtained area.

10.1.3 Mechanical smoke exhaust systems shall be designed in accordance with Sections 10.2 through 10.4.

10.2 Exhaust Rates. Exhaust rates per curtained area shall be not less than the mass plume flow rates, $\dot{m}_p$, as determined in accordance with 9.2.3, unless it can be demonstrated that a lower exhaust rate will prevent the smoke from descending below the design level of the smoke layer boundary during the design period.

10.3 Fire Exposure.

10.3.1 Mechanical smoke exhaust systems shall be capable of functioning under the expected fire exposure.

10.3.2 The temperature of the smoke layer shall be determined in accordance with 9.2.4.3 and 9.2.4.4.

10.4* Number of Exhaust Inlets.

10.4.1 The minimum number of exhaust inlets shall be determined so that the maximum flow rates for exhaust without plugholing are not exceeded.

10.4.2 More than the minimum number of exhaust inlets required shall be permitted.

10.4.3* The maximum volumetric flow rate that can be exhausted by a single exhaust inlet without plugholing shall be calculated using Equation 10.4.3.

$$V_{max} = 4.16\gamma d^{5/2}\left(\frac{T_s - T_o}{T_o}\right)^{1/2} \quad \textbf{[10.4.3]}$$

where:

V_{max} = maximum volumetric flow rate without plugholing at T_s (m^3/sec)
γ = exhaust location factor (dimensionless)
d = depth of smoke layer below the lowest point of the exhaust inlet (m)
T_s = absolute temperature of the smoke layer (K)
T_o = absolute ambient temperature (K)

10.4.4* For exhaust inlets centered no closer than twice the diameter from the nearest wall, a value of 1 shall be used for γ.

10.4.5* For exhaust inlets centered less than twice the diameter from the nearest wall, a value of 0.5 shall be used for γ.

10.4.6* For exhaust inlets on a wall, a value of 0.5 shall be used for γ.

10.4.7* The ratio d/D_i shall be greater than 2, where D_i is the diameter of the inlet.

10.4.8 For rectangular exhaust inlets, D_i shall be calculated using Equation 10.4.8 as follows:

$$D_i = \frac{2ab}{a+b} \quad \textbf{[10.4.8]}$$

where:

D_i = diameter of exhaust inlet
a = length of the inlet
b = width of the inlet

10.4.9 Where multiple exhaust inlets are required to prevent plugholing *(see 10.4.1)*, the minimum separation distance shall be calculated using Equation 10.4.9 as follows:

$$S_{min} = 0.9V_e^{1/2} \quad \textbf{[10.4.9]}$$

where:

S_{min} = minimum edge-to-edge separation between inlets (m)
V_e = volumetric flow rate of one exhaust inlet (m^3/s)

10.5 Intake Air. Intake air shall be provided to make up air required to be exhausted by the mechanical smoke exhaust systems. *(See Chapter 6 for additional information on the location of air inlets.)*

Chapter 11 Venting in Sprinklered Buildings

11.1* Design. Where provided, the design of venting for sprinklered buildings shall be based on an engineering analysis acceptable to the AHJ, demonstrating that the established objectives are met. *(See Section F.3.)*

11.2* Automatic Sprinkler Systems. The automatic sprinkler system shall be designed in accordance with NFPA 13.

11.3* Storage Occupancies Protected by Control Mode Sprinklers.

11.3.1 Where draft curtains are provided, they shall be located over the longitudinal center of an aisle.

11.3.2 The aisle width shall not be less than 1.5 times the spacing between sprinklers in the direction perpendicular to the draft curtain.

11.3.3 Sprinklers shall be located on both sides of the curtain per NFPA 13 requirements for sprinkler placement with respect to walls.

11.3.4 The aisle width required by 11.3.2 shall not be required if a full height partition is used in lieu of a draft curtain.

Chapter 12 Inspection and Maintenance

12.1* General. Smoke and heat venting systems and mechanical smoke exhaust systems shall be inspected and maintained in accordance with Chapter 12.

12.2* Requirements.

12.2.1 Mechanically Opened Vents. Mechanically opened vents shall be provided with manual release devices that allow direct activation to facilitate inspection, maintenance, and replacement of actuation components.

12.2.2 Thermoplastic Drop-Out Vents. Thermoplastic drop-out vents do not allow nondestructive operation; however, inspection of installed units shall be conducted to ensure that the units are installed in accordance with the manufacturer's instructions and that all components are in place, undamaged, and free of soiling, debris, and extraneous items that might interfere with the operation and function of the unit.

12.2.3 Inspection and Maintenance. The inspection and maintenance of multiple-function vents shall ensure that other functions do not impair the intended fire protection operation.

12.3 Inspection, Maintenance, and Acceptance Testing.

12.3.1 Inspection Schedules.

12.3.1.1 A written inspection schedule and procedures for inspection and maintenance shall be developed.

12.3.1.2 Inspection programs shall provide written notations of the date and time of inspections and of discrepancies found.

12.3.1.3 All deficiencies shall be corrected immediately.

12.3.1.4* Vents shall be inspected and maintained in an operating condition in accordance with Chapter 12.

12.3.2 Mechanically Opened Vents.

12.3.2.1 An acceptance performance test and inspection of all mechanically opened vents shall be conducted immediately following installation to establish that all operating mechanisms function properly and that installation is in accordance with this standard and the manufacturer's specifications.

12.3.2.2* Mechanically opened vents shall be inspected and subjected to an operational test annually, following the manufacturer's recommendations.

12.3.2.3* All pertinent characteristics of performance shall be recorded.

12.3.2.4 Special mechanisms, such as gas cylinders, thermal sensors, or detectors, shall be checked annually or as specified by the manufacturer.

12.3.3 Thermoplastic Drop-Out Vents.

12.3.3.1* An acceptance inspection of all thermoplastic drop-out vents shall be conducted immediately after installation and shall include verification of compliance with the manufacturer's drawings and recommendations by visual examination.

12.3.3.2* Thermoplastic drop-out vents shall be inspected annually in accordance with 12.4.2 and the manufacturer's recommendations.

12.3.3.3 Changes in appearance, damage to any components, fastening security, weather tightness, and the adjacent roof and flashing condition shall be noted at the time of inspection, and any deficiency shall be corrected.

12.3.3.4 Any soiling, debris, or encumbrances that could impair the operation of the vent shall be promptly removed without causing damage to the vent.

12.3.4 Inlet Air Sources. Where required for the operation of vent systems, intake air sources shall be inspected at the same frequency as vents.

12.4 Conduct and Observation of Operational Tests.

12.4.1 Mechanically Opened Vents and Air Inlets.

12.4.1.1 Mechanically opened vents and air inlets shall be operated during tests by simulating actual fire conditions.

12.4.1.2 The restraining cable at the heat-responsive device (or other releasing device) shall be disconnected, releasing the restraint and allowing the trigger or latching mechanism to operate.

12.4.1.3* When the heat-responsive device restraining cable for mechanically opened vents or air inlets is under tension, observation shall be made of its whip and travel path to determine any possibility that the vent, building construction feature, or service piping could obstruct complete release. Any interference shall be corrected by removal of the obstruction, enclosure of cable in a suitable conduit, or other appropriate arrangement.

12.4.1.4 Following any modification, the unit shall be retested for evaluation of adequacy of corrective measures.

12.4.1.5 Latches shall release smoothly and the vent or air inlet shall open immediately and move through its design travel to the fully opened position without any assistance and without any problems such as undue delay indicative of a sticking weather seal, corroded or unaligned bearings, or distortion binding.

12.4.1.6 Manual releases shall be tested to verify that the vents and air inlets operate as designed.

12.4.1.7 All operating levers, latches, hinges, and weather-sealed surfaces shall be examined to determine conditions, such as deterioration and accumulation of foreign material. An operational test shall be conducted after corrections are completed, when conditions are found to warrant corrective action.

12.4.1.8 Following painting of the interior or exterior of vents and air inlets or the addition of sealants or caulking, the units shall be opened and inspected to check for paint, sealants, or caulking that causes the parting surfaces to adhere to each other.

12.4.1.9 Heat-responsive devices coated with paint or other substances that could affect their response shall be replaced with devices having an equivalent temperature and load rating.

12.4.2 Thermoplastic Drop-Out Vents.

12.4.2.1 All weather-sealed surfaces on thermoplastic drop-out vents shall be examined to determine any adverse conditions, such as any indication of deterioration and accumulation of foreign material. Any adverse condition that interferes with normal vent operation, such as caulking or sealant bonding the drop-out vent to the frame, shall be corrected.

12.4.2.2 Following painting of the interior or exterior of the frame or flashing of the vents, the units shall be inspected for paint adhering surfaces together; any paint that interferes with normal operation shall be removed or the vent shall be replaced with a new, listed and labeled unit having comparable operating characteristics.

12.4.2.3 Manual releases shall be tested annually.

12.4.3 Inspection, Maintenance, and Testing of Mechanical Smoke-Exhaust Systems.

12.4.3.1 Component Testing.

12.4.3.1.1 The operational testing of each individual system component of the mechanical smoke-exhaust system shall be performed as each component is completed during construction.

12.4.3.1.2 It shall be documented in writing that each individual system component's installation is complete and that the component has been tested and found to be functional.

12.4.3.2 Acceptance Testing.

12.4.3.2.1 Acceptance tests shall be conducted to demonstrate that the mechanical smoke-exhaust system installation complies with and meets the design objectives and is functioning as designed.

12.4.3.2.2 Documentation from component system testing shall be available for review during final acceptance testing.

12.4.3.2.3 If standby power has been provided for the operation of the mechanical smoke-exhaust system, the acceptance testing shall be conducted while on both normal and standby power.

12.4.3.2.4 Acceptance testing shall be performed on the mechanical smoke-exhaust system by completing the following steps:

(1) Activate the mechanical smoke-exhaust system.
(2) Verify and record the operation of all fans, dampers, doors, and related equipment.

(3) Measure fan exhaust capacities, air velocities through inlet doors and grilles, or at supply grilles if there is a mechanical makeup air system.

12.4.3.2.5 Operational tests shall be performed on the applicable part of the smoke-exhaust system wherever there are system changes and modifications.

12.4.3.2.6 Upon completion of acceptance testing, a copy of all operational testing documentation shall be provided to the owner and shall be maintained and made available for review by the AHJ.

12.4.3.3 Periodic Testing.

12.4.3.3.1 Mechanical smoke-exhaust systems shall be tested semiannually by persons who are knowledgeable in the operation, testing, and maintenance of the systems.

12.4.3.3.2 The results of the tests shall be documented and made available for inspection.

12.4.3.3.3 Tests shall be conducted under standby power where applicable.

12.4.3.4 Exhaust System Maintenance.

12.4.3.4.1 During the life of the building, maintenance shall be performed to ensure that mechanical smoke-exhaust systems will perform their intended function under fire conditions.

12.4.3.4.2 Maintenance of the systems shall include the testing of all equipment, including initiating devices, fans, dampers, and controls.

12.4.3.4.3 Equipment shall be maintained in accordance with the manufacturer's recommendations.

12.4.3.5 Inspection Schedule.

12.4.3.5.1 A written inspection schedule and procedures for inspection and maintenance for mechanical smoke-exhaust systems shall be developed.

12.4.3.5.2 Inspection programs shall provide written notations of date and time of inspections and for discrepancies found.

12.4.3.5.3 All system components shall be inspected semiannually in conjunction with operational tests.

12.4.3.5.4 Any deficiencies noted in the system components or smoke-exhaust system performance shall be corrected immediately.

12.5 Air Inlets.

12.5.1 Air inlets necessary for operation of smoke and heat vents or mechanical smoke-exhaust systems shall be maintained clear and free of obstructions.

12.5.2 Operating air inlet louvers, doors, dampers, and shutters shall be examined and operated to assure movement to fully open positions.

12.5.3 Operating equipment shall be maintained and lubricated as necessary.

12.6 Ice and Snow Removal. Ice and snow shall be removed from vents promptly, following any accumulation.

Chapter 13 Design Documentation

13.1* Documentation Required. All of the following documents shall be generated by the designer during the design process:

(1) Design brief
(2) Conceptual design report
(3) Detailed design report
(4) Operations and maintenance manual

13.1.1 Design Brief. The design brief shall contain a statement of the goals and objectives of the vent system and shall provide the design assumptions to be used in the conceptual design.

13.1.1.1 The design brief shall include, as a minimum, all of the following:

(1) System performance goals and design objectives *(see Section 4.1 and 4.4.1)*
(2) Performance criteria (including design tenability criteria, where applicable)
(3) Building characteristics (height, area, layout, use, ambient conditions, other fire protection systems)
(4) Design basis fire(s) *(see 4.5.2 and Chapter 8)*
(5) Design fire location(s)
(6) Identified design constraints
(7) Proposed design approach

13.1.1.2 The design brief shall be developed in the first stage of the design process to assure that all stakeholders understand and agree to the goals, objectives, design fire, and design approach, so that the conceptual design can be developed on an agreed-upon basis. Stakeholders shall include, as a minimum, the building owner and the AHJ.

13.1.2 Conceptual Design Report. The conceptual design report shall provide the details of the conceptual design, based upon the design brief, and shall document the design calculations.

13.1.2.1 The conceptual design shall include, as a minimum, all of the following design elements and the technical basis for the design elements:

(1) Areas of curtained spaces
(2) Design depth of the smoke layer and draft curtain depth
(3) Detection method, detector characteristics, and spacing
(4) Design interval time (if applicable)
(5) Vent size and number per curtained area, method of vent operation, and vent spacing
(6) Inlet vent area(s), location(s), and operation method

13.1.2.2 The conceptual design report shall include all design calculations performed to establish the design elements, all design assumptions, and all building use limitations that arise out of the system design.

13.1.3 Detailed Design Report.

13.1.3.1 The detailed design report shall provide documentation of the vent system as it is to be installed.

13.1.3.2 The detailed design report shall include, as a minimum, all of the following:

(1) Vent and draft curtain specifications
(2) Inlet and vent operation system specifications

(3) Detection system specifications
(4) Detailed inlet, vent, and draft curtain siting information
(5) Detection and vent operation logic
(6) Systems commissioning procedures

13.1.4 Operations and Maintenance Manual. The operations and maintenance manual shall provide to the building owner the requirements to ensure the intended operation of the vent system over the life of the building.

13.1.4.1 The procedures used in the initial commissioning of the vent system shall be described in the manual, as well as the measured performance of the system at the time of commissioning.

13.1.4.2 The manual shall describe the testing and inspection requirements for the system and system components and the required frequency of testing. *(See Chapter 12 for testing frequency.)*

13.1.4.3 The manual shall describe the critical design assumptions used in the design and shall provide limitations on the building and its use that arise out of the design assumptions and limitations.

13.1.4.4 Copies of the operations and maintenance manual shall be provided to the owner and to the AHJ.

13.1.4.5 The building owner shall be responsible for all system testing and shall maintain records of all periodic testing and maintenance using the operations and maintenance manual.

13.1.4.6 The building owner shall be responsible for providing a copy of the operations and maintenance manual, including testing results, to all tenants of the space protected by the vent system.

13.1.4.7 The building owner and tenants shall be responsible for limiting the use of the space in a manner consistent with the limitations provided in the operations and maintenance manual.

Annex A Explanatory Material

Annex A is not a part of the requirements of this NFPA document but is included for informational purposes only. This annex contains explanatory material, numbered to correspond with the applicable text paragraphs.

A.1.1.1 This standard incorporates engineering equations (hand calculations) and references models to provide a designer with the tools to develop vent system designs. The designs are based on selected design objectives, stated in 4.4.1, related to specific building and occupancy conditions. Engineering equations are included for calculating vent flows, smoke layer depths, and smoke layer temperatures, based on a prescribed burning rate. Examples using the hand calculations and the LAVENT (Link-Actuated VENTs) computer model are presented in Annex D.

Previous editions of this document have included tables listing vent areas based on preselected design objectives. These tables were based on the hot upper layer at 20 percent of the ceiling height. Different layer depths were accommodated by using a multiplication factor. Draft curtain and vent spacing rules were set. Minimum clear visibility times were related to fire growth rate, ceiling height, compartment size, curtain depth, and detector activation times, using engineering equations.

The following list provides a general description of the significant phenomena that occur during a fire when a fire-venting strategy is implemented:

(1) Due to buoyancy, hot gases rise vertically from the combustion zone and flow horizontally below the roof until blocked by a vertical barrier (a wall or draft curtain), thus forming a layer of hot gases below the roof.
(2) The volume and temperature of gases to be vented are a function of the fire's rate of heat release and the amount of air entrained into the buoyant plume produced.
(3) As the depth of the layer of hot gases increases, the layer temperature continues to rise and the vents open.
(4) The operation of vents within a curtained area enables some of the upper layer of hot gases to escape and thus slows the thickening rate of the layer of hot gases. With sufficient venting area, the thickening rate of the layer can be arrested and even reversed. The rate of discharge through a vent of a given area is primarily determined by the depth of the layer of hot gases and the layer temperature. Adequate quantities of replacement inlet air from air inlets located below the hot upper layer are needed if the products of combustion-laden upper gases are to be exhausted according to design. See Figure A.1.1.1(a) for an illustration of the behavior of fire under a vented and curtained roof, and Figure A.1.1.1(b) for an example of a roof with vents.

The majority of the information provided in this standard applies to nonsprinklered buildings. A limited amount of guidance is provided in Chapter 11 for sprinklered buildings.

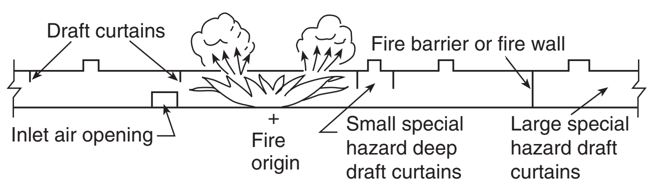

FIGURE A.1.1.1(a) Behavior of Combustion Products Under Vented and Curtained Roof.

FIGURE A.1.1.1(b) View of Roof Vents on Building.

The provisions of this standard can be applied to the top story of multiple-story buildings. Many features of these provisions would be difficult or impracticable to incorporate into the lower stories of such buildings.

A.1.1.2 The decision whether to provide venting in a building depends on design objectives set by a building owner or occupant or on local building code and fire code requirements.

A.1.3.1 See NFPA 90A for ventilation to regulate environmental air for personnel comfort. See NFPA 96 for regulation of commercial cooking operations. See NFPA 68 for venting for explosion pressure relief.

A.1.3.4 The distance from the fire base to the smoke layer boundary, z_s, is a dominant variable and should be considered carefully. Additionally, some design situations can result in smoke layer temperatures, as expressed in Equation 9.2.4.3, that exceed 600°C (1112°F). In such cases, the radiation from the smoke layer can be sufficient to ignite all of the combustibles under the curtained area at this temperature, and perhaps in the adjacent area, which is unacceptable.

A.1.3.5 The feasibility of roof venting should be questioned when the heat release rate approaches values associated with ventilation control of the burning process (i.e., where the fire becomes controlled by the inlet air replacing the vented hot gas and smoke). Ventilation-controlled fires might be unable to support a clear layer.

To maintain a clear layer, venting at heat release rates greater than $Q_{feasible}$ necessitates vent areas larger than those indicated by the calculation scheme provided in this standard.

A.1.3.6 Large, undivided floor areas present extremely difficult fire-fighting problems because the fire department might need to enter these areas in order to combat fires in central portions of the building. If the fire department is unable to enter because of the accumulation of heat and smoke, fire-fighting efforts might be reduced to an application of hose streams to perimeter areas while fire continues in the interior. Windowless buildings also present similar fire-fighting problems. One fire protection tool that can be a valuable asset for fire-fighting operations in such buildings is smoke and heat venting.

An appropriate design time facilitates such activities as locating the fire, appraising the fire severity and its extent, evacuating the building, and making an informed decision on the deployment of personnel and equipment to be used for fire fighting.

A.2.1 Some of these documents might also be referenced in this standard for specific informational purposes and are therefore also listed in Annex G.

A.3.2.1 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

A.3.2.2 Authority Having Jurisdiction (AHJ). The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A.3.2.4 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A.3.3.3 Clear Layer Interface. See Figure A.3.3.3 for a description of the smoke layer interface, smoke layer, and first indication of smoke.

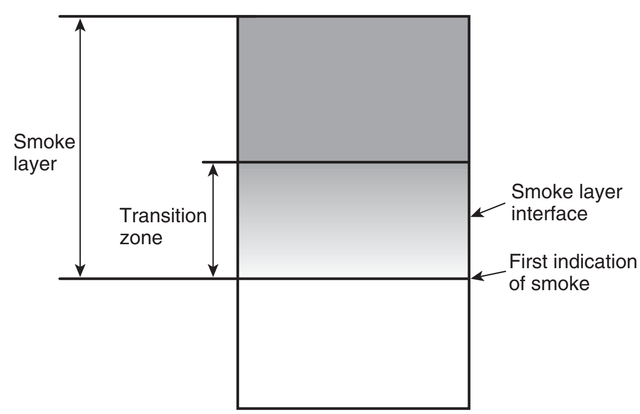

FIGURE A.3.3.3 First Indication of Smoke.

A.3.3.9 Draft Curtain. A draft curtain can be a solid fixed obstruction such as a beam, girder, soffit, or similar material. Alternately, a deployable barrier can be used that descends to a fixed depth during its operation.

A.3.3.10 Effective Ignition. See Figure 8.3.1 for a conceptual illustration of continuous fire growth and effective ignition time.

A.3.3.18 Smoke Layer. See Figure A.3.3.3 for a description of the clear layer interface, smoke layer, and smoke layer boundary.

A.3.3.19 Smoke Layer Boundary. See Figure A.3.3.3 for a description of the clear layer interface, smoke layer, and smoke layer boundary.

A.4.1 Design objectives for a vent system can include one or more of the following goals:

(1) To provide occupants with a safe path of travel to a safe area
(2) To facilitate manual fire fighting
(3) To reduce the damage to buildings and contents due to smoke and hot gases

A.4.2 Tests and studies provide a basis for the division of occupancies into classes, depending on the fuel available for contribution to fire. Wide variation is found in the quantities of combustible materials in the many kinds of buildings and areas of buildings.

A.4.4.2 The heat release rate of a fire, the fire diameter, and the height of the clear layer above the base of the fire are major factors affecting the production of smoke.

A.4.4.3 Mass flow through a vent is governed mainly by the vent area and the depth of the smoke layer and its temperature. Venting becomes more effective with smoke temperature differentials between ambient temperature and an upper layer of approximately 110°C (230°F) or higher. Where temperature differences of less than 110°C (230°F)are expected, vent flows might be reduced significantly; therefore, consideration should be given to using powered exhaust. NFPA 92 should be consulted for guidance for power venting at these lower temperatures.

The vent designs in this standard allow the fire to reach a size such that the flame plume enters the smoke layer. Flame height may be estimated using Equation 9.2.3.1.

A.4.5.1 The rate of smoke production depends on the rate of air entrainment into a column of hot gases produced by and located above a fire. Entrainment is affected by the fire diameter and rate of heat release, and it is strongly affected by the distance between the base of the fire and the point at which the smoke plume enters the smoke layer.

A.4.5.2 Because smoke production is related to the size of a fire, it follows that, all factors being equal, larger fires produce more smoke. Entrainment, however, is strongly affected by the distance between the base of a fire and the bottom of the hot layer. The base of the fire (where combustion and entrainment begin) should be selected on the basis of the worst case. It is possible for a smaller fire having a base near the floor to produce more smoke than a larger fire with a base at a higher elevation. Air entrainment is assumed to be limited to the clear height between the base of the fire and the bottom of the hot layer. The buoyant plume associated with a fire produces a flow into the hot upper layer. As the plume impinges on the ceiling, the plume turns and forms a ceiling jet. The ceiling jet flows radially outward along the ceiling.

A.4.5.3 Where the possibility of multiple fires and, therefore, multiple plumes exists, smoke production rates increase beyond the rate predicted for a single plume for a fire of equivalent output. Multiple fires are beyond the scope of this standard.

A.4.5.3.2 Plume mass flow above the flame level is based on the concept that, except for absolute scales, the shapes of velocity and temperature profiles at the mean flame height are invariable. This concept leads to an expression for mass flow above the flames that involves the so-called *virtual origin*, a point source from which the plume above the flames appears to originate. The virtual origin might be above or below the base of the fire.

A.4.6.1 It is assumed that openings exist to the outside and therefore no pressure results from the expansion of gases. Also, wind effects are not taken into account because wind might assist or interfere with vent flows, depending on specific circumstances. It is also assumed that the fire environment in a building space is divided into two zones — a hot upper layer and a relatively cool, clear (comparatively free of smoke) lower region. When a fire grows to a size approaching ventilation-limited burning, the building might no longer maintain a clear lower region, and this standard would no longer be applicable. Finally, caution must be exercised when using this standard for conditions under which the upper-gas-layer temperature approaches 600°C (1112°F), because flashover might occur within the area. When a fire develops to flashover or ventilation-limited burning, the relationships provided in this standard are not applicable.

Buoyancy pressure is related to the depth of the hot layer, the absolute temperature of the hot layer, the temperature rise above ambient of the hot layer, and the density of the ambient air. The mass rate of flow of hot gases through a vent is a function of vent area, layer depth, and hot layer temperature. The temperature of the hot layer above ambient affects mass flow through a vent. Maximum flow occurs at temperature differences of approximately 300°C (572°F)above ambient. Flows at other temperature differentials are diminished, as shown in Figure A.4.6.1.

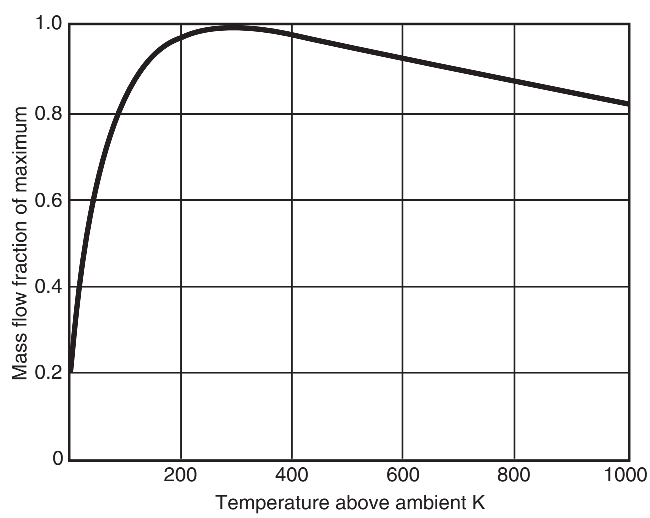

FIGURE A.4.6.1 Effect of Temperature on Mass Flow Through a Vent.

A.4.6.1.2 In order to provide a design that is not dependent on beneficial wind effects, design calculations are carried out that ignore wind effects and that are based only on buoyancy effects (and fan assistance for mechanical systems).

Nevertheless, it is important to consider wind effects since adverse wind effects can reduce or even reverse vent flow. Exhaust vents and air inlets should be located so that under any wind conditions there is an overall wind suction effect from inlet to exhaust.

This is normally achieved when the roof slope is 30 degrees or less and vents have a horizontal clear space at least three times the height difference from any taller structures such as parapets, roof lights, or taller roofs.

Otherwise, if the designer cannot show by calculation or by data that there will be no adverse wind effects, a mechanical smoke extract system should be used.

A.4.6.2 To function as intended, a building venting system needs sufficiently large fresh air inlet openings at low levels. It is essential that a dependable means for admitting or supplying inlet air be provided promptly after the first vent opens.

A.5.1 There is an ISO standard for vents (ISO DIS 21927-2, *Specification for natural smoke and heat exhaust ventilators*). The ISO standard is technically equivalent to European (EN) standards for these products. Products that carry the CE mark, which is mandatory for sale of these products within the European Union, are subject to independent testing and ongoing factory production control by Notified Bodies appointed by national governments. The standard is EN 12101-2, *Specification for natural smoke and heat exhaust ventilators.*

A.5.2.1 Compatibility between the vent-mounting elements (e.g., holding power, electrochemical interaction, wind lift, building movement) and the building structure to which they are attached needs to be ensured.

A.5.2.2 To avoid inadvertent operation, it is important that the actuating means be selected with regard to the full range of expected ambient conditions.

A.5.2.3 Dip tanks or discrete solvent storage areas are examples of localized hazards where the vents are to be located directly above such hazard.

A.5.3.1 An automatic mechanism for opening the roof vents is stipulated for effective release of heat, smoke, and gaseous by-products. The means of automatic vent actuation must take the anticipated fire into consideration, and an appropriate means of opening vents should be used. If design objectives cannot be met using heat-actuated devices, smoke detectors with appropriate linkages to open vents or other devices that respond more quickly should be considered for use.

A.5.3.2 Latching mechanisms should be jam-proof, corrosion-resistant, dust-resistant, and resistant to pressure differences arising from applicable positive or negative loading resulting from environmental conditions, process operations, overhead doors, or traffic vibrations.

A.5.3.5 The location of the manual device must be coordinated with tactics of the reporting fire department.

If not actually mounted on the vent, the manual device can be connected to the vent by mechanical, electrical, or any other suitable means, protected as necessary to remain operable for the design period.

A.5.4.1.2 See Figure 5.4.2(b) for the measurement of ceiling height and curtain board depth.

A.5.4.2 The spacing of vents is limited to 4*H* to assure that ceiling jet temperatures at the vent are sufficiently high to operate the thermal actuating mechanism at the vent. The spacing limit specified is designed to achieve ceiling jet temperature above ambient at the nearest vent, not less than half the plume temperature above ambient at the point of plume impact on the ceiling. (See Figure A.5.4.2, which reflects the maximum allowable spacing of 4*H*.)

A.5.4.3 The limitation on horizontal distance from a potential fire axis adjacent to a draft curtain or wall is intended to assure ceiling jet temperatures at the vent are sufficiently high to activate the thermal actuating mechanism. The spacing limit specified is designed to achieve ceiling jet temperature above ambient at the nearest vent, not less than half the plume temperature above ambient at the point of plume impact on the ceiling. *(See Figure A.5.4.3.)* This requirement does not reflect the potential for reduced entrainment for a fire adjacent to a wall. This conservatism was knowingly accepted.

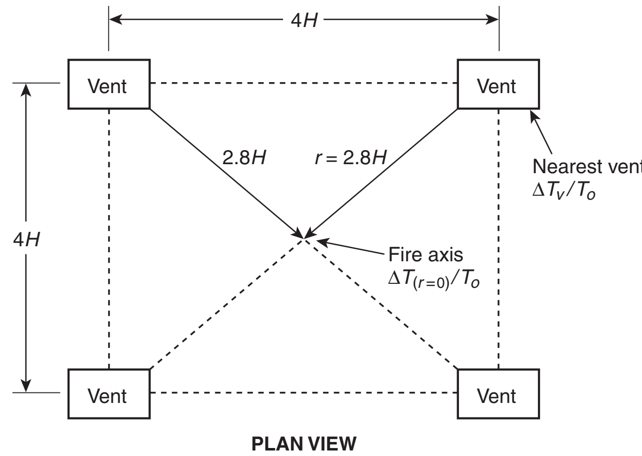

FIGURE A.5.4.2 Vent Spacing in Rectangular Matrix, When $r = 2.8H$, $(\Delta T_v/T_o) = 0.5\ (\Delta T(r = 0)/T_o)$ (plan view).

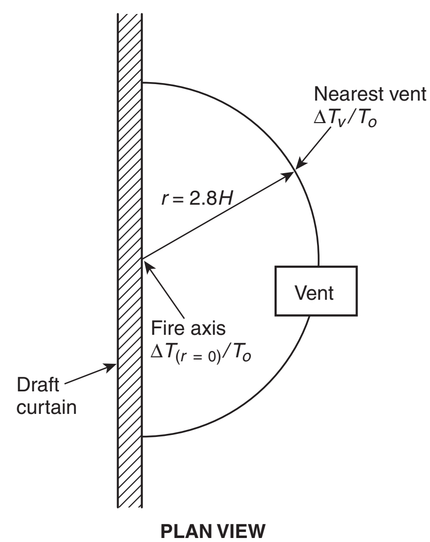

FIGURE A.5.4.3 Vent Spacing near a Draft Curtain, When $r = 2.8H$, $(\Delta T_v/T_o) = 0.5\ (\Delta T(r = 0/T_o)$ (plan view).

A.6.1 The simplest method of introducing makeup air into the space is through direct openings to the outside, such as doors and louvers, which can be opened upon system activation. Such openings can be coordinated with the architectural design and can be located as required below the design smoke layer. For locations having mechanical smoke exhaust systems where such openings are impractical, a powered supply system could be considered. This could possibly be an adaptation of the building's HVAC system if capacities, outlet grille locations, and velocities are suitable. For such systems, means should be provided to prevent supply systems from operating until exhaust flow has been established, to avoid pressurization of the fire area. For those locations where climates are such that the damage to the space or contents could be extensive during testing or frequent inadvertent operation of the system, consideration should be given to heating the makeup air. See NFPA 92 for additional information on mechanical systems.

A.6.3 Normal practice has been to provide air inlet from low-level air inlets as recommended in previous editions of this standard. In some buildings this may be difficult to achieve, due either to lack of suitable clear wall area or to concerns about loss of security when the air inlets open. In buildings containing more than one curtained area, it can be possible to open vents in curtained areas not affected by smoke to provide inlet air instead. If this is done, then the vents must meet all the requirements of Chapter 6.

A.6.6.3 The inlet air velocity should be limited for three reasons: (1) to avoid disturbing the fire plume and causing excess air entrainment, (2) to limit the degree of depressurization of the space and consequent effects on door opening and closing, and (3) to avoid incoming air hampering escape of occupants.

NFPA 92 sets a limit of 1.02 m/s (200 ft/min) to minimize disturbance of the plume, which will create more entrainment than anticipated.

Excess depressurization of the space will increase door opening forces for outward-opening doors and risk slamming closed for inward-opening doors. Neither situation is acceptable.

Research indicates that people can move reasonably freely against an airflow of up to 10 m/s (32.8 ft/s).

A.7.1 Draft curtains are provided for prompt activation of vents and to increase vent effectiveness by containing the smoke in the curtained area and increasing the depth of the smoke layer. A draft curtain is intended to be relatively smoke-tight. The function of a draft curtain is to intercept the ceiling jet and the entrained smoke produced by a fire in the building. The curtain should prevent the smoke from spreading along the underside of the roof deck to areas of the building located beyond the draft curtain and should create a hot smoke layer that develops buoyancy forces sufficient to exhaust the smoke through the vent openings in the roof. A full-height partition or wall, including an exterior wall, can serve as a draft curtain.

A.7.2 Materials suitable for use as draft curtains can include steel sheeting, cementitious panels, and gypsum board or any materials that meet the performance criteria in Section 7.2. There is an ISO standard for draft curtains (ISO DIS 21927-1, *Specification for smoke barriers*). The ISO standard is technically equivalent to the European (EN) standard for these products. Products that carry the CE mark, which is mandatory for sale of these products within the European Union, are subject to independent testing and ongoing factory production control by Notified Bodies appointed by national governments. The standard is EN 12101-1, *Specification for smoke barriers*.

A.7.3.1 If d_c exceeds 20 percent of H, $H–d_c$ should be not less than 3 m (9.8 ft). For Figure 5.4.2(b), parts (a) through (d), this concept is valid where $\Delta d/d_c$ is much less than 1.

Consideration should be given to minimizing of the expected smoke layer depth with respect to the occupancy. Such arrangement can allow the smoke layer to be maintained above the top of equipment or storage, thus maximizing visibility and reducing nonthermal damage to contents. For buildings of limited height, it can also allow the designer to utilize the primary structural frame to act as a draft curtain (if solid-webbed) or support one (if open-webbed), thus reducing costs.

Also, in a transient situation, prior to achieving equilibrium mass flow, if the smoke layer extends below the top of equipment or storage, that volume displaced by equipment or storage should be subtracted from available space for the smoke layer to accumulate, or the smoke layer depth will extend below that estimated.

A.7.4.1 To ensure that vents remote from the fire within the curtained compartment are effective, the distance between draft curtains or between walls must be limited.

A.7.4.2 From reanalysis of this issue based on Delichatsios [1981], Heskestad and Delichatsios [1978], and Koslowski and Motevalli [1994].

A.8.1 Chapter 8 presents techniques for predicting the heat release rate of various fuel arrays likely to be present in buildings where smoke and heat venting is a potential fire safety provision. It primarily addresses the estimation of fuel concentrations found in storage and manufacturing locations. NFPA 92 addresses the types of fuel arrays more common to the types of building situations covered by that document. The methods provided in Chapter 8 for predicting the rate of heat release are based on "free burning" conditions, in which no ceiling or smoke layer effects are involved.

A.8.2.2 The minimum aisle width to prevent lateral spread by radiation, W_{min} in Equation 8.2.3, is based on Alpert and Ward [1984]. The values produced by Equation 8.2.3 can be produced from the following equation if χ_r is assumed to be 0.5:

$$\dot{q}''_i = \frac{\chi_r}{4\pi r^2} \quad \textbf{[A.8.2.2]}$$

A.8.2.6 The heat release rate is taken as the heat release rate per unit area times the floor area of the fuel concentration. The maximum foreseeable storage height (above the fire base) and associated heat release rate should be considered.

The heat release rate per unit area might be available from listings for a given storage height, such as Table A.8.2.6. To establish estimates for other than specified heights, it can be assumed that the heat release rate per unit area is proportional to the storage height, based on tests (Yu and Stavrianidis, 1991) and the data in Table A.8.2.6 for wood pallets. For fuel configurations that have not been tested, other procedures should be used. See Annex E for estimating heat release rates of other fuel arrays.

There is a distinct possibility that a combustible storage array could collapse before the end of the design interval of the venting system. The design interval might end, for example, when manual fire fighting is expected to begin. The fire diameter increases, contributing to increased smoke production (via a lower flame height and virtual origin). However, the heat release rate and fire growth rate after collapse are likely to be smaller than with no collapse. Consequently, it is reasonable to assume that the net effect of collapse is not significant for the calculation procedure.

Table A.8.2.6 Unit Heat Release Rates for Commodities

Commodity	Heat Release Rate (kW per m² of floor area)*
Wood pallets, stacked 0.46 m high (6%–12% moisture)	1,420
Wood pallets, stacked 1.52 m high (6%–12% moisture)	4,000
Wood pallets, stacked 3.05 m high (6%–12% moisture)	6,800
Wood pallets, stacked 4.88 m high (6%–12% moisture)	10,200
Mail bags, filled, stored 1.52 m high	400
Cartons, compartmented, stacked 4.5 m high	1,700
PE letter trays, filled, stacked 1.5 m high on cart	8,500
PE trash barrels in cartons, stacked 4.5 m high	2,000
FRP shower stalls in cartons, stacked 4.6 m high	1,400
PE bottles packed in compartmented cartons, stacked 4.5 m high	6,200
PE bottles in cartons, stacked 4.5 m high	2,000
PU insulation board, rigid foam, stacked 4.6 m high	1,900
PS jars packed in compartmented cartons, stacked 4.5 m high	14,200
PS tubs nested in cartons, stacked 4.2 m high	5,400
PS toy parts in cartons, stacked 4.5 m high	2,000
PS insulation board, rigid foam, stacked 4.2 m high	3,300
PVC bottles packed in compartmented cartons, stacked 4.5 m high	3,400
PP tubs packed in compartmented cartons, stacked 4.5 m high	4,400
PP and PE film in rolls, stacked 4.1 m high	6,200
Methyl alcohol	740
Gasoline	2,500
Kerosene	1,700
Fuel oil, no. 2	1,700

PE: polyethylene. PP: polypropylene. PS: polystyrene. PU: polyurethane. PVC: polyvinyl chloride. FRP: fiberglass-reinforced polyester.

*Heat release rate per unit floor area of fully involved combustibles, based on negligible radiative feedback from the surroundings and 100 percent combustion efficiency.

A.8.3.1 The growth time, t_g, is a measure of the fire growth rate — the smaller the growth time, the faster the fire grows.

A.8.3.2 By comparing Equations 8.3.1 and 8.3.2, the following relation exists:

$$\alpha_g = \frac{1000}{t_g^2} \quad \textbf{[A.8.3.2]}$$

A.8.3.4 Design objectives and the design interval time, t_r, should take into consideration all of the following critical events:

(1) Arrival and deployment of the emergency response team
(2) Arrival and deployment of fire fighters from the public fire department
(3) Completion of evacuation
(4) Other critical events

A.9.1 The procedures in Chapter 9 are based on the automatic activation of vents by a heat-responsive device with an established response time index (RTI) and known activation temperature. These assumptions do not preclude other means of vent activation, as long as the activation time of the alternative means is known or can be calculated using the procedures contained herein or can be established as acceptable by a specific listing, specific test data, or engineering analysis. Activation by heat detectors, smoke detectors, thermoplastic drop-out vent panels, or other approved means is acceptable as long as the design objectives are met.

The equations and procedures for hand calculations in Section 9.2 and the models in Section 9.3 address the venting of limited-growth fires and continuously growing fires.

A.9.1.1 The vent area in a curtained area should not be required to exceed the vent area calculated for the largest limited-growth fire predicted for the combustibles beneath any curtained area. Using sufficiently small concentrations of combustibles and aisles of sufficient width to prevent spread according to Equation 8.2.3, it might be possible to satisfy venting requirements by using vent areas smaller than those required for a vent design and a continuous-growth fire.

A.9.1.4 Many large facilities have buildings or areas subject to differing fire hazards.

A.9.2.2.1 In Figure 9.2.2.1, z_s is the height of the smoke layer boundary above the base of the fire; H is the distance between the base of the fire and the ceiling; d_c is the depth of the draft curtains; d is the depth of the smoke layer; $\dot{m}_p$ is the mass flow rate of hot gas from the fire plume into the smoke layer; $\dot{m}_v$ is the mass flow rate of hot gas out of the vent (or vents) in the curtained area; and A_v is the vent area in the curtained area (total vent area in the curtained area if more than one vent is provided).

The vent area calculated for equilibrium conditions corresponds to the area needed for a long-term steady fire or to the area needed at the end of a design interval for a slow-growing fire. For shorter-term steady fires and for faster-growing fires, the calculated equilibrium vent area will prevent the smoke layer boundary from descending completely to the bottom of the draft curtains. Therefore, equilibrium calculations represent a safety factor in the design.

A.9.2.3.1 The mass flow rate in the plume depends on whether locations above or below the mean flame height are considered (i.e., whether the flames are below the smoke layer boundary or reach into the smoke layer).

A.9.2.4 The calculations in this section assume that the vent is exhausting only smoke from the smoke layer. When the smoke layer is at its design depth, the provisions for avoidance of plugholing in Section 5.4 will ensure that this is so.

However, during part of the time period when the smoke layer is descending to its design height, the vents will extract a mixture of smoke from the smoke layer and the ambient air from below the smoke layer. They will therefore extract less smoke than the calculations indicate, causing the smoke layer to descend at a faster rate.

Existing research has provided formulae to assess at what point a vent starts plugholing, but not to assess the smoke extract rate while a vent is plugholing.

There is therefore no experimentally validated method of assessing the effect of plugholing on the rate of descent of a smoke layer. A method has been published in BS 7346-5, *Functional recommendations and calculation methods for smoke and heat exhaust ventilation systems employing time-dependent design fires.*

A.9.2.4.1 The mass flow rate through the vent is the product of gas density, velocity, and cross-sectional area of the flow in the vent. The velocity follows from equating the buoyancy head across the vent to the dynamic head in the vent, with consideration of the pressure drop across the air inlets. The factor $[(T_o\Delta T)/T^2]^{1/2}$ is quite insensitive to temperature as long as the smoke layer temperature rise, ΔT, is not small. For example, assuming T_o = 294 K, the factor varies through 0.47, 0.50, and 0.47 as the smoke layer temperature rise varies through 150 K, 320 K, and 570 K. At a temperature rise of 60 K, the factor is 0.38, and at a temperature rise of 20 K, it is 0.24, or about one-half its maximum value. Consequently, roof venting by natural ventilation becomes increasingly less effective as the smoke layer temperature decreases. For low smoke layer temperatures, powered ventilation as covered in NFPA 92 should be considered.

Where high upper-layer temperatures of 400 K above ambient are anticipated, 80 percent of the predicted vent flow is expected to be achieved with an inlet area/vent area ratio of 1, whereas it is expected that 90 percent of the vent flow will result from a ratio of 2. Where relatively low upper-layer temperatures, such as 200 K above ambient, are expected, a ratio of inlet air/vent area of 1 would result in about 70 percent of the predicted vent flow, whereas a ratio of 2 would be expected to produce about 90 percent of the predicted vent flow.

A.9.2.4.2 The aerodynamic vent area is always smaller than the geometric vent area, A_v. A discharge coefficient of 0.6 should be reasonable for most vents and for doors and windows that open at least 45 degrees. However, the discharge coefficient can be different for other types of openings. For example, an opening with a louver can have a coefficient ranging between 0.1 and 0.4.

A.9.2.5.4.1 For continuous-growth fires, the earlier the fire is detected and vents actuated, the smaller the fire size at the end of the design interval and the smaller the required vent area. In the case of limited-growth fires, the earlier the fire is detected and the vents actuated, the less likely to occur are an initial underspill of smoke at the draft curtains and smoke layer descent to low heights.

If a design objective is to confine smoke to the curtained area of origin, the time the last required vent opens, t_{vo}, should not exceed the time the smoke layer boundary drops below draft curtains, which can be determined in accordance with Equation A.9.2.5.4.1a for steady fires and Equation A.9.2.5.4.1b for unsteady fires.

$$\frac{z_{si}}{H} = 0.67 - 0.28 \ln\left[\frac{\left(tQ^{1/3}/H^{4/3}\right)}{\left(A_c/H^2\right)}\right] \quad \textbf{[A.9.2.5.4.1a]}$$

$$\frac{z_{si}}{H} = 0.23\left[\frac{t}{t_g^{\,2/5}\left(H^{4/5}\right)\left(A_c/H^2\right)^{3/5}}\right]^{-1.45} \quad \textbf{[A.9.2.5.4.1b]}$$

where:

z_{si} = height of smoke layer interface above the base of the fire
t = time (s)
Q = total heat release rate
H = ceiling height above base of fire
A_c = curtained area being filled with smoke (m^2)

A.9.2.5.4.2.1 The response data in *NFPA 72* assume extensive, flat, horizontal ceilings.

This assumption might appear optimistic for installations involving beamed ceilings. However, any delay in operation due to beams is at least partially offset by the opposite effects of the following:

(1) Heat banking up under the ceiling because of draft curtains or walls
(2) The nearest vent or detector usually being closer to the fire than the assumed, greatest possible distance

Fusible links are commonly used as actuators for mechanically opened heat and smoke vents. Where the response time index (RTI) and fusing temperature of a fusible link are known, and assuming that the link is submerged in the ceiling jet, the relationships described in *NFPA 72* for heat-actuated alarm devices can be used to estimate the opening of a mechanical vent.

A.9.2.5.4.3.1 This requirement does not have a parallel in *NFPA 72*. Temperature rise for activation of smoke detectors depends on the specific detector as well as the material undergoing combustion. Limited data on temperature rise at detection have previously been recorded in the range of 2°C to 42°C, depending on the detector/material combination [Heskestad and Delichatsios, 1977].

A.9.2.5.4.4.1 A computer program known as DETACT-T2 (Detector Actuation — time squared) [Evans and Stroup, 1985] is available for calculating the detection times of heat detectors or fusible links in continuous-growth, *t*-squared fires. DETACT-T2 assumes the detector is located in a large compartment with an unconfined ceiling, where there is no accumulation of hot gases at the ceiling. Thus, heating of the detector is only from the flow of hot gases along the ceiling. Input data consist of ceiling height, time constant or RTI of the detector, operating temperature, distance of the detector from plume centerline, and fire growth rate. The model calculates detection times for smoke detectors *(see 9.2.5.4.3)* based on the predecessor equations. The predecessor equations assume complete combustion of the test fuel used in the experiments used to develop the equations based on the actual heat of combustion:

$$\frac{u}{\left(\Delta T_g/T_o\right)gH^{1/2}} = 0.59\left(\frac{r}{H}\right)^{-0.63} \quad \textbf{[A.9.2.5.4.4.1]}$$

where:

u = gas velocity at detector site
r = radius from fire axis
ΔT_g = gas temperature rise from ambient at detector/sprinkler site
T_o = ambient air temperature
g = acceleration of gravity
H = ceiling height (above combustibles)

However, DETACT-T2 can still be used, provided that the projected fire growth coefficient, α_g, is multiplied by the factor 1.67. In addition, when DETACT-T2 is used, the outputs of heat release rate at detector response from the program calculations must be divided by 1.67 in order to establish heat release rates at detector response.

A.9.2.5.4.4.2 Another program, DETACT-QS (Detector Actuation — quasi-steady) [Evans and Stroup, 1985], is available for calculating detection times of heat detectors, fusible links, and smoke detectors in fires of arbitrary fire growth. DETACT-QS assumes that the detector is located in a large compartment with an unconfined ceiling, where there is no accumulation of hot gases at the ceiling. Thus, heating of the detector is only from the flow of hot gases along the ceiling. Input data consist of ceiling height, time constant or RTI of the detector, operating temperature, distance of the detector from the plume centerline, and fire growth rate. The model calculates detection times for smoke detectors *(see 9.2.5.4.3)* based on the predecessor equations. Quasi-steady temperatures and velocities are assumed (i.e., instantaneously, gas temperatures and velocities under the ceiling are assumed to be related to the heat release rate as in a steady fire). Compared to DETACT-T2, DETACT-QS provides a means of addressing fires that cannot be approximated as *t*-squared fires. However, for *t*-squared fires, DETACT-QS is less accurate than DETACT-T2 (if the projected fire growth coefficient is increased as described in 9.2.5.4.4.1 and A.9.2.5.4.4.1), especially for fast-growing fires.

A.10.1 There is an ISO standard for mechanical smoke extract (ISO DIS 21927-3, *Specification for powered smoke and heat exhaust ventilators*). The ISO standard is technically equivalent to the European (EN) standard for these products. Products that carry the CE mark, which is mandatory for sale of these products within the European Union, are subject to independent testing and ongoing factory production control by Notified Bodies appointed by national governments. The standard is EN 12101-3, *Specification for powered smoke and heat exhaust ventilators.*

A.10.1.1 Where temperature differences of less than 110°C (230°F) are expected, vent flows might be reduced significantly; therefore, consideration should be given to using powered exhaust. NFPA 92 should be consulted for guidance for power venting at these lower temperatures.

A.10.4 The sizing and spacing of exhaust fan intakes should balance the following concerns:

(1) The exhaust intakes need to be sufficiently close to one another to prevent the smoke from cooling to the point that it loses buoyancy as it travels along the underside of the ceiling to an intake and descends from the ceiling. This is particularly important for spaces where the length is greater than the height, such as shopping malls.
(2) The exhaust intakes need to be sized and distributed in the space to minimize the likelihood of air beneath the smoke layer from being drawn through the layer. This phenomenon is called plugholing.

The objective of distributing fan inlets is therefore to establish a gentle and generally uniform rate over the entire smoke layer. To accomplish this, the velocity of the exhaust inlet should not exceed the value determined from Equation A.10.4.

For plugholing calculations, the smoke temperature should be calculated as follows:

$$T = T_o + \frac{KQ_c}{mC_p} \qquad \textbf{[A.10.4]}$$

where:

T = smoke layer temperature (°F)
T_o = ambient temperature (°F)
K = fraction of convective energy contained in the smoke layer gases
Q_c = convective portion of heat release (Btu/sec)
m = mass flow rate of the plume (lb/sec)
C_p = specific heat of plume gases (0.24 Btu/lb-°F)

A value of $K = 0.5$ is suggested unless more detailed information is available.

A.10.4.3 The plugholing equation of this paragraph is consistent with and derived from the scale model studies of Spratt and Heselden [1974]. The equation is also consistent with the recent study of Nii, Nitta, Harada, and Yamaguchi [2003].

A.10.4.4 The γ factor of 1.0 applies to ceiling vents remote from a wall. *Remote* is regarded as a separation greater than two times the depth of the smoke layer below the lower point of the exhaust opening.

A.10.4.5 The γ factor of 0.5 is based upon potential flow considerations for a ceiling vent adjacent to a wall. While γ should vary smoothly from 0.5 for a vent directly adjacent to a wall to 1.0 for a ceiling vent remote from a wall, the available data do not support this level of detail in the requirements of the standard.

A.10.4.6 The γ factor of 0.5 is used for all wall vents. Because no data exist for wall exhausts, a value of γ greater than 0.5 could not be justified.

A.10.4.7 Noise due to exhaust fan operation or due to velocity at the exhaust inlet should be limited to allow the fire alarm signal to be heard.

A.11.1 Chapters 4 through 10 represent the state of technology of vent and draft curtain board design in the absence of sprinklers. A broadly accepted equivalent design basis for using sprinklers, vents, and curtain boards together for hazard control (e.g., life safety, property protection, water usage, obscuration) is currently not available. Designers are cautioned that the use of venting with automatic sprinklers is an area of ongoing research to determine its benefit and effect in conjunction with automatic suppression. See Section F.3 for more information.

A.11.2 Smoke and heat vents should be designed not to adversely impact the performance of the automatic sprinkler system. See 12.1.1 of NFPA 13. Testing and computer model studies conducted to date that have addressed the interaction of smoke and heat vents have been limited to control mode sprinklers. Because ESFR sprinklers have not been considered in any such studies, use of the guidance in this document is not applicable to ESFR sprinklers. The RTI is considerably lower than, and the required water discharge per sprinkler is considerably higher than, those of control mode sprinklers. There is concern that early operation of a smoke and heat venting system could adversely affect the performance of the fire suppression provided by ESFR sprinklers.

A.11.3 Figure A.11.3 shows the recommended spacing of sprinklers with respect to the draft curtain locations.

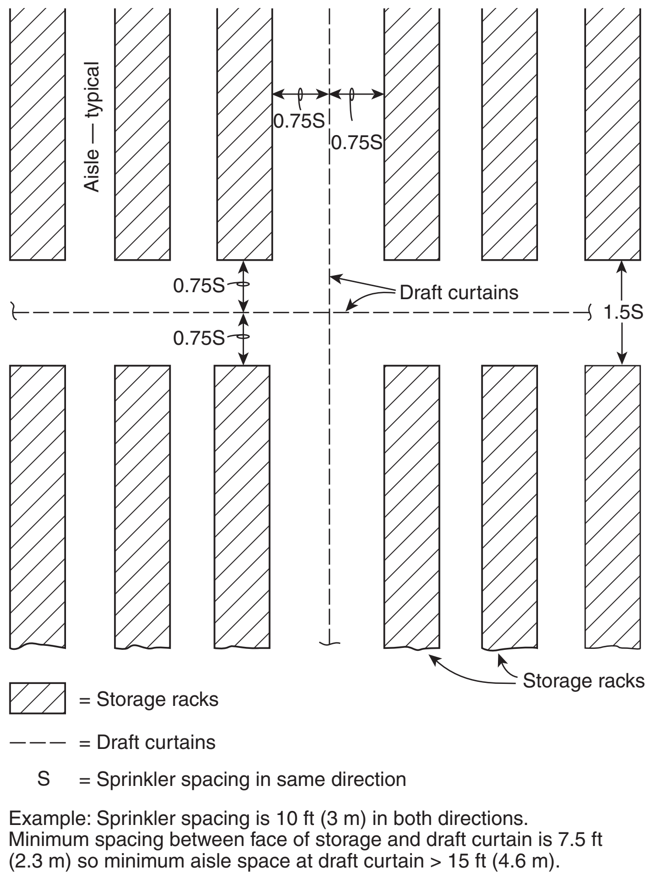

FIGURE A.11.3 Recommended Sprinkler Spacing with Respect to Draft Curtain Locations.

A.12.1 Regular inspection and maintenance is essential for emergency equipment and systems that are not subjected to their intended use for many years.

A.12.2 Various types of approved automatic thermal smoke and heat vents are available commercially. These vents fall into the following two general categories:

(1) Mechanically opened vents, which include spring-lift, pneumatic-lift, or electric motor-driven vents
(2) Thermoplastic drop-out vents, which include polyvinyl chloride (PVC) or acrylic drop-out panels

Thermoplastic drop-out vents do not allow nondestructive operation.

A.12.3.1.4 Vents designed for multiple functions (e.g., the entrance of daylight, roof access, comfort ventilation) need maintenance of the fire protection function that might be impaired by the other uses. These impairments can include loss of spring tension; racking or wear of moving parts; adverse exterior cooling effects on the fire protection release mechanism; adverse changes in performance sequence, such as premature heat actuation leading to opening of the vent; or reduced sensitivity to heat.

A.12.3.2.2 Inspection schedules should include provisions for testing all units at 12-month intervals or on a schedule based on a percentage of the total units to be tested every month or every two months. Such procedures improve reliability. A change in occupancy, or in neighboring occupancies, and in materials being used could introduce a significant change in the nature or severity of corrosive atmosphere exposure, debris accumulation, or physical encumbrance and could necessitate a change in the inspection schedule.

A.12.3.2.3 Recording and logging of all pertinent characteristics of performance allows results to be compared with those of previous inspections or acceptance tests and thus provides a basis for determining the need for maintenance or for modifying the frequency of the inspection schedule to fit the experience.

A.12.3.3.1 The same general considerations for inspection that apply to mechanically opened vents also pertain to thermoplastic drop-out vents. The thermoplastic panels of these vents are designed to soften and drop out from the vent opening in response to the heat of a fire. This makes an operational test after installation impracticable. Recognized fire protection testing laboratories have developed standards and procedures for evaluating thermoplastic drop-out vents, including factory and field inspection schedules. It is suggested that laboratory recommendations be followed for the field inspection of such units.

A.12.3.3.2 Thermoplastic drop-out vents utilize various types of plastics such as PVC and acrylic. Without the presence of ultraviolet (UV) stabilizers, exposure to UV rays can cause degradation and failure of the thermoplastic component (dome). Indication of UV degradation includes yellowing, browning, or blackening of the dome, as well as cracking or a brittle texture of the dome. (This condition can prevent proper operation of the thermoplastic material; i.e., it will not operate at its design activation temperature.) Corrective action requires replacing the thermoplastic dome with a dome having an equivalent thermal response.

A.12.4.1.3 The whipping action of the cable on release presents a possibility of injury to anyone in the area. For this reason, the person conducting the test should ensure that all personnel are well clear of the area where whipping of the cable might occur.

A.13.1 Design documentation is critical to the proper installation, operation, and maintenance of the smoke and heat vent systems. It forms the basis for evaluating the system's adequacy to perform as intended if the building or its use is modified.

Annex B The Theoretical Basis of LAVENT

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

B.1 Overview. This annex develops the physical basis and an associated mathematical model for estimating the fire-generated environment and the response of sprinkler links in well-ventilated compartment fires with curtain boards and ceiling vents actuated by heat-responsive elements such as fusible links or thermoplastic drop-out panels. Complete equations and assumptions are presented. Phenomena taken into account include the following:

(1) Flow dynamics of the upward-driven, buoyant fire plume
(2) Growth of the elevated-temperature smoke layer in the curtained compartment
(3) Flow of smoke from the layer to the outside through open ceiling vents
(4) Flow of smoke below curtain partitions to building spaces adjacent to the curtained space of fire origin
(5) Continuation of the fire plume in the upper layer
(6) Heat transfer to the ceiling surface and the thermal response of the ceiling as a function of radial distance from the point of plume–ceiling impingement
(7) Velocity and temperature distribution of plume-driven near-ceiling flows and the response of near-ceiling–deployed fusible links as functions of distance below the ceiling
(8) Distance from plume–ceiling impingement

The theory presented here is the basis of the LAVENT computer program that is supported by a user guide, which is presented in Annex C, and that can be used to study parametrically a wide range of relevant fire scenarios [1–3].

B.2 Introduction. The space under consideration is a space of a plan area, A, defined by ceiling-mounted curtain boards with a fire of time-dependent energy release rate, $\dot{Q}(t)$, and with open ceiling vents of total time-dependent area, $A_V(t)$. The curtained area can be considered as one of several such spaces in a large building compartment. Also, by specifying that the curtains be deep enough, they can be thought of as simulating the walls of a single, uncurtained compartment. This annex presents the physical basis and associated mathematical model for estimating the fire-generated environment and the response of sprinkler links in curtained compartment fires with ceiling vents actuated by heat-responsive elements such as fusible links or thermoplastic drop-out panels.

The overall building compartment is assumed to have near-floor wall vents that are large enough to maintain the inside environment, below any near-ceiling smoke layers that could form, at assumed initial outside-ambient conditions. Figure F.2(a) depicts the generic fire scenario for the space under consideration. The assumption of large near-floor wall vents necessitates that the modeling be restricted to conditions where y, the elevation of the smoke layer interface, is above the floor elevation (i.e., $y > 0$). The assumption also has important implications with regard to the cross-ceiling vent pressure differential. This is the pressure differential that drives elevated-temperature upper-layer smoke through the ceiling vents to the outside. Therefore, below the smoke layer (i.e., from the floor of the facility to the elevation of the smoke layer interface), the inside-to-outside hydrostatic pressure differential exists at all elevations in the reduced-density smoke layer itself (higher pressure inside the curtained area, lower pressure in the outside environment), the maximum differential occurring at the ceiling and across the open ceiling vents.

B.3 The Basic Equations. A two-layer, zone-type compartment fire model is used to describe the phenomena under investigation. As is typical in such models, the upper smoke layer of total mass, m_U, is assumed to be uniform in density, ρ_U, and absolute temperature, T_U.

The following time-dependent equations describe conservation of energy, mass, and the perfect gas law in the upper smoke layer.

Conservation of energy,

$$\frac{d\left[\left(y_{ceil}-y\right)\rho_U T_U A C_V\right]}{dt} = \dot{q}_U + \left(\rho A \frac{dy}{dt}\right) \quad \textbf{[B.3a]}$$

Conservation of mass,

$$\frac{dm_U}{dt} = \dot{m}_U \quad \textbf{[B.3b]}$$

$$m_U = \left(y_{ceil}-y\right)\rho_U A \quad \textbf{[B.3c]}$$

Perfect gas law,

$$\frac{\rho_U}{R} \propto \frac{\rho}{R} = constant = \rho_U T_U = \rho_{amb} T_{amb} \quad \textbf{[B.3d]}$$

That is,

$$T_U = \frac{T_{amb}\rho_{amb}}{\rho_U} \quad \textbf{[B.3e]}$$

In the preceding equations, y_{ceil} is the elevation of the ceiling above the floor, $R = C_p\text{-}C_V$ is the gas constant, C_p and C_V are the specific heats at a constant pressure and volume, respectively, and p is a constant characteristic pressure (e.g., p_{atm}) at the floor elevation. In Equation B.3a, $\dot{q}_U$ is the net rate of enthalpy flow plus heat transfer to the upper layer and is made up of flow components as follows: $\dot{q}_{curt}$, from below the curtain; $\dot{q}_{plume}$, from the plume; $\dot{q}_{vent}$, from the ceiling vent; and the component $\dot{q}_{HT}$, the total heat transfer rate.

$$\dot{q}_U = \dot{q}_{curt} + \dot{q}_{plume} + \dot{q}_{vent} + \dot{q}_{HT} \quad \textbf{[B.3f]}$$

In Equation B.3b, $\dot{m}_U$ is the net rate of mass flow to the upper layer with flow components; $\dot{m}_{curt}$, from below the curtain; $\dot{m}_{plume}$, from the plume; and $\dot{m}_{vent}$, from the ceiling vent.

$$\dot{m}_U = \dot{m}_{curt} + \dot{m}_{plume} + \dot{m}_{vent} \quad \textbf{[B.3g]}$$

Using Equation B.3c in Equation B.3a leads to

$$\frac{dy}{dt} = \frac{\dot{q}_U}{AC_\rho p_{amb} T_{amb}} \quad \textbf{[B.3h]}$$

if

$$y = y_{ceil} \text{ and } \dot{q}_U \geq 0$$

or

$$0 < y > y_{ceil} \text{ and } \dot{q}_U \text{ is arbitrary}$$

Because both of these conditions are satisfied, Equation B.3h is always applicable.

The basic problem of mathematically simulating the growth and properties of the upper layer for the generic Figure F.2(a) scenario necessitates the solution of the system of Equation B.3b and Equation B.3h for m_U and y. When $m_U > 0$,

ρ_U can be computed from Equation B.3c according to the following:

$$\rho_U = \frac{(y_{ceil} - y)A}{m_U};\ \text{if } m_U > 0 \qquad \textbf{[B.3i]}$$

and T_U can be determined from Equation B.3e.

B.4 Mass Flow and Enthalpy Flow Plus Heat Transfer.

B.4.1 Flow to the Upper Layer from the Vents. Conservation of momentum across all open ceiling vents as expressed by Bernoulli's equation leads to the following:

$$V = C\left(\frac{2\Delta\rho_{ceil}}{\rho_U}\right)^{1/2} \qquad \textbf{[B.4.1a]}$$

$$\dot{m}_{vent} = -\rho_U A_V V = -A_V C\left(2\rho_U \Delta\rho_{ceil}\right)^{1/2} \qquad \textbf{[B.4.1b]}$$

where:
V = the average velocity through all open vents
C = the vent flow coefficient (0.68) [4]
$\Delta\rho_{ceil}$ = the cross-vent pressure difference

From hydrostatics,

$$\begin{aligned}\Delta\rho_{ceil} &= \rho_U(y = y_{ceil}) - \rho_{amb}(y = y_{ceil}) \\ &= (\rho_{amb} - \rho_U)g(y_{ceil} - y)\end{aligned} \qquad \textbf{[B.4.1c]}$$

where:
g = the acceleration of gravity

Substituting Equation B.4.1c into Equation B.4.1b leads to the desired $\dot{m}_{vent}$ result, as follows:

$$\dot{m}_{vent} = -A_V C\left[2\rho_U(\rho_{amb} - \rho_U)g(y_{ceil} - y)\right]^{1/2} \qquad \textbf{[B.4.1d]}$$

which is equivalent to the equations used to estimate ceiling vent flow rates *(see Equation 9.2.4.1 and references [5] and [6])*. Using Equation B.4.1d, the desired $\dot{q}_{vent}$ result is as follows:

$$\dot{q}_{vent} = \dot{m}_{vent} C_P T_U \qquad \textbf{[B.4.1e]}$$

B.4.2 Flow to the Layer from the Plume and Radiation from the Fire. It is assumed that the mass generation rate of the fire is small compared to $\dot{m}_{ent}$, the rate of mass of air entrained into the plume between the fire elevation, y_{fire}, and the layer interface, or compared to other mass flow rate components of $\dot{m}_U$. It is also assumed that all of the $\dot{m}_{ent}$ penetrates the layer interface and enters the upper layer. Therefore,

$$\dot{m}_{plume} = \dot{m}_{ent} \qquad \textbf{[B.4.2a]}$$

$$\dot{q}_{plume} = \dot{m}_{ent} C_P T_{amb} + (1 - \lambda_r)\dot{Q} \qquad \textbf{[B.4.2b]}$$

The first term on the right side of Equation B.4.2b is the enthalpy associated with $\dot{m}_{ent}$, and λ_r, in the second term in Equation B.4.2b, is the effective fraction of $\dot{Q}$ assumed to be radiated isotropically from the fire's combustion zone.

It is assumed that the smoke layer is relatively transparent and that it does not participate in any significant radiation heat transfer exchanges. In particular, all of the $\lambda_r Q$ radiation is assumed to be incident on the bounding surfaces of the compartment. Therefore, the last term of Equation B.4.2b is the net amount of enthalpy added to the upper layer from the combustion zone and its buoyancy-driven plume. Flaming fires exhibit values for λ_r of $0 < \lambda_r < 0.6$ (e.g., smallest values for small methane fires and highest values for large polystyrene fires). However, for a hazardous fire involving a wide range of common groupings of combustibles, it is reasonable to approximate flame radiation by choosing $\lambda \propto 0.35$ [7].

A specific plume entrainment model is necessary to complete Equations B.4.1e and B.4.2a for $\dot{m}_{plume}$ and $\dot{q}_{plume}$. The following estimate for $\dot{m}_{ent}$ [8, 9] is adopted as follows:

$$\dot{m}_{ent} = \left|\begin{array}{l} 0;\ \text{if } y - y_{fire} \le 0; \\ 0.0054\left[(1-\lambda_r)\dot{Q}\right]\dfrac{y - y_{fire}}{L_{flame}};\ \text{if } 0 < \dfrac{y - y_{fire}}{L_{flame}} < 1 \\ 0.071\left[(1-\lambda_r)\dot{Q}\right]^{1/3} \\ \times\left\{(y - y_{fire} - L_{flame}) + 0.166\left[(1-\lambda_r)\dot{Q}\right]^{2/5}\right\}^{5/3} \\ \times\left[\begin{array}{l} 1 + \in\left[(1-\lambda_r)\dot{Q}\right]^{2/3} \\ \times\left\{(y - y_{fire} - L_{flame}) + 0.166\left[(1-\lambda_r)\dot{Q}\right]^{2/5}\right\}^{-5/3} \end{array}\right]; \\ \quad \text{if } \dfrac{y - y_{fire}}{L_{flame}} \ge 1 \end{array}\right. \qquad \textbf{[B.4.2c]}$$

where $\dot{m}_{ent}$ is in kg/s, $\dot{Q}$ is in kW, and y, y_{fire}, L_{flame} are in m and where

$$\frac{L_{flame}}{D_{fire}} = \left|\begin{array}{l} 0;\quad \text{if } \dfrac{0.249\left[(1-\lambda_r)\dot{Q}\right]^{2/5}}{D_{fire}} - 1.02 < 0 \\ \dfrac{0.249\left[(1-\lambda_r)\dot{Q}\right]^{2/5}}{D_{fire}} - 1.02; \\ \quad \text{if } \dfrac{0.249\left[(1-\lambda_r)\dot{Q}\right]^{2/5}}{D_{fire}} - 1.02 \ge 0 \end{array}\right. \qquad \textbf{[B.4.2d]}$$

where $\dot{Q}$ is in kW, D_{fire} is in m, and

$$\in = \left(\frac{0.0054}{0.071}\right) - (0.166)^{5/3} = 0.02591682\ldots \approx 0.026 \qquad \textbf{[B.4.2e]}$$

In Equations B.4.2c through B.4.2e,
L_{flame} is the fire's flame length.
D_{fire} is the effective diameter of the fire source ($\pi D^2_{fire}/4$ = area of the fire source).
$\in$ is chosen so that, analytically, the value of $\dot{m}_{ent}$ is exactly continuous at the elevation $y = y_{fire} + L_{flame}$.

B.4.3 Flow to the Layer from Below the Curtains. If the upper layer interface, y, drops below the elevation of the bottom of the curtains, y_{curt}, mass and enthalpy flows occur from the upper layer of the curtained area where the fire is located to adjacent curtained areas of the overall building compartment. The mass flow rate is the result of hydrostatic cross-curtain pressure differentials. Provided adjacent curtained areas are not yet filled with smoke, this pressure difference increases linearly from zero at the layer interface to Δp_{curt} at $y = y_{curt}$.

From hydrostatics,

$$\begin{aligned}\Delta\rho_{curt} &= \rho_U(y = y_{curt}) - \rho_{amb}(y = y_{curt}) \\ &= (\rho_{amb} - \rho_U)g(y_{curt} - y)\end{aligned} \qquad \textbf{[B.4.3a]}$$

Using Equation B.4.3a together with well-known vent flow relations (e.g., Equation 32 of reference [4]), $\dot{m}_{curt}$ and $\dot{q}_{curt}$ can be estimated from the following:

$$\dot{m}_{curt} = \begin{cases} 0; & \text{if } y \geq y_{curt} \\ -\dfrac{L_{curt}}{3}\left[8\left(y_{curt}-y\right)^3 \rho_U \left(\rho_{amb}-\rho_U\right) g\right]^{1/2}; & \text{if } y \leq y_{curt} \end{cases} \quad \textbf{[B.4.3b]}$$

$$\dot{q}_{curt} = \dot{m}_{curt} C_P T_U \quad \textbf{[B.4.3c]}$$

where L_{curt} is that length of the perimeter of the curtained areas of the fire origin that is connected to other curtained areas of the overall building compartment. For example, if the curtained area is in one corner of the building compartment, then the length of its two sides coincident with the walls of the compartment are not included in L_{curt}. Because the generic vent flow configuration under consideration in this case is long and deep, a flow coefficient for the vent flow incorporated into Equation B.4.3b is taken to be 1.

B.4.4 Heat Transfer to the Upper Layer. As discussed in B.4.3, where the fire is below the layer interface, the buoyant fire plume rises toward the ceiling, and all of its mass and enthalpy flow, $\dot{m}_{plume}$ and $\dot{q}_{plume}$, are assumed to be deposited into the upper layer. Having penetrated the interface, the plume continues to rise toward the ceiling of the curtained compartment. As it impinges on the ceiling surface, the plume flow turns and forms a relatively high-temperature, high-velocity, turbulent ceiling jet that flows radially outward along the ceiling and transfers heat to the relatively cool ceiling surface. The ceiling jet is cooled by convection, and the ceiling material is heated by conduction. The convective heat transfer rate is a strong function of the radial distance from the point of plume–ceiling impingement and reduces rapidly with increasing radius. It is dependent also on the characteristics of the plume immediately upstream of ceiling impingement.

The ceiling jet is blocked eventually by the curtains, wall surfaces, or both. It then turns downward and forms vertical surface flows. In the case of wall surfaces and very deep curtains, the descent of these flows is stopped eventually by upward buoyant forces, and they finally mix with the upper layer. In this case, it is assumed that the plume–ceiling impingement point is relatively far from the closest curtain or wall surface (e.g., greater than a few fire-to-ceiling lengths). Under such circumstances, the ceiling jet–wall flow interactions are relatively weak, and compared to the net rate of heat transfer from the ceiling and near the plume–ceiling impingement point, the heat transfer to the upper layer from all vertical surfaces is relatively small.

Define λ_{conv} as the fraction of $\dot{Q}$ that is transferred by convection from the upper-layer gas ceiling jet to the ceiling and to the vertical wall and curtain surfaces as follows:

$$\dot{q}_{HT} = -\lambda_{conv}\dot{Q} \quad \textbf{[B.4.4]}$$

Once the values of $\lambda_{conv}\dot{Q}$ and $\dot{q}_{HT}$ are determined from a time-dependent solution to the coupled, ceiling jet–ceiling material, convection-conduction problem, the task of determining an estimate for each component of $\dot{q}_U$ and $\dot{m}_U$ in Equations B.3f and B.3g, respectively, is complete.

B.4.4.1 Properties of the Plume in the Upper Layer When y_{fire} < y. Those instances of the fire elevation being below the interface (i.e., when $y_{fire} < y$) are considered here.

As the plume flow moves to the center of the upper layer, the forces of buoyancy that act to drive the plume toward the ceiling (i.e., as a result of relatively high-temperature, low-density plume gases being submerged in a relatively cool, high-density ambient environment) are reduced immediately because of the temperature increase of the upper-layer environment over that of the lower ambient. As a result, the continued ascent of the plume gases is less vigorous (i.e., ascent is at reduced velocity) and of higher temperature than it would be in the absence of the layer. Indeed, some of the penetrating plume flow will be at a lower temperature than T_U. The upper-layer buoyant forces on this latter portion of the flow actually retard and can possibly stop its subsequent rise to the ceiling.

A simple point-source plume model [10] is used to simulate the plume flow, first immediately below or upstream of the interface and then throughout the depth of the upper layer itself.

A plume above a point source of buoyancy [10], where the source is below the interface, will be considered to be equivalent to the plume of a fire (in the sense of having identical mass and enthalpy flow rates at the interface) if the point-source strength is $(1 - \lambda_r)\dot{Q}$ and the elevation of the equivalent source, y_{eq}, satisfies the following:

$$\dot{m}_{plume} = 0.21\rho_{amb} g^{1/2} \left(y - y_{eq}\right)^{5/2} \dot{Q}_{eq}^{*1/3} \quad \textbf{[B.4.4.1a]}$$

In Equation B.4.4.1a, $\dot{Q}_{eq}^*$, a dimensionless measure of the strength of the fire plume at the interface, is defined as follows:

$$\dot{Q}_{eq}^* = \frac{\left(1-\lambda_r\right)\dot{Q}}{\rho_{amb} C_P T_{amb} g^{1/2} \left(y - y_{eq}\right)^{5/2}} \quad \textbf{[B.4.4.1b]}$$

It should be noted that at an arbitrary moment of time on the simulation of a fire scenario, $\dot{m}_{plume}$ in Equation B.4.4.1a, is a known value that is determined previously from Equations B.4.2a and B.4.2c.

Using Equations B.4.4.1a and B.4.4.1b to solve for y_{eq} and $\dot{Q}_{eq}^*$,

$$y_{eq} = y - \left[\frac{\left(1-\lambda_r\right)\dot{Q}}{\dot{Q}_{eq}^* \rho_{amb} C_P T_{amb} g^{1/2}}\right]^{2/5} \quad \textbf{[B.4.4.1c]}$$

$$\dot{Q}_{eq}^* = \left[\frac{0.21\left(1-\lambda_r\right)\dot{Q}}{C_P T_{amb} \dot{m}_{plume}}\right]^{3/2} \quad \textbf{[B.4.4.1d]}$$

As the plume crosses the interface, the fraction, $\dot{m}^*$, of $\dot{m}_{plume}$, that is still buoyant relative to the upper-layer environment and presumably continues to rise to the ceiling, entraining upper-layer gases along the way, is predicted [11] to be as follows:

$$\dot{m}^* = \begin{cases} 0; & \text{if } -1 < \sigma \leq 0 \\ \dfrac{1.04599\sigma + 0.360391\sigma^2}{1.0 + 1.37748\sigma + 0.360391\sigma^2}; & \text{if } \sigma > 0 \end{cases} \quad \textbf{[B.4.4.1e]}$$

where the dimensionless parameter, σ, is defined as follows:

$$\sigma = \frac{1 - \alpha + C_T \dot{Q}_{eq}^{*2/3}}{\alpha - 1} \quad \textbf{[B.4.4.1f]}$$

$$\alpha = \frac{T_U}{T_{amb}} \quad \textbf{[B.4.4.1g]}$$

where C_T = 9.115 and where $\dot{Q}_{eq}^*$ is the value computed in Equation B.4.4.1d.

The parameters necessary to describe plume flow continuation in the upper layer (i.e., between y and y_{ceil}) are further identified [11] according to a point-source plume [10]. It has been determined that this plume can be modeled as being driven by a nonradiating buoyant source of strength, $\dot{Q}'$, located a distance

$$H = y_{ceil} - y'_{source} > y_{ceil} - y_{fire} \qquad \textbf{[B.4.4.1h]}$$

below the ceiling in a downward-extended upper-layer environment of temperature, T_U, and density, ρ_U. The relevant parameters predicted [11] are as follows:

$$\dot{Q}' = \frac{(1-\lambda_r)\dot{Q}\sigma\dot{m}^*}{1+\sigma} \qquad \textbf{[B.4.4.1i]}$$

$$y'_{source} = y - (y - y_{eq})\alpha^{3/5}\dot{m}^{*2/5}\left(\frac{1+\sigma}{\sigma}\right)^{1/5} \qquad \textbf{[B.4.4.1j]}$$

The fire and the equivalent source in the lower layer and the continuation source in the upper layer are depicted in Figure B.4.4.1, parts (a) through (c). Those times during a fire simulation when Equation B.4.4. 1f predicts $\sigma > 1$ are related to states of the fire environment in which the temperature distribution above T_{amb} of the plume flow, at the elevation of interface penetration, is predicted to be mostly much larger than $T_U - T_{amb}$. Under such circumstances, the penetrating plume flow is still very strongly buoyant as it enters the upper layer. The plume continues to rise to the ceiling and to drive ceiling jet convective heat transfer at rates that differ only slightly (due to the elevated temperature upper-layer environment) from the heat transfer rates that could occur in the absence of an upper layer.

Conditions where Equation B.4.4.1f predicts $\sigma < 0$ are related to times during a fire scenario when the temperature of the plume at the elevation of interface penetration is predicted to be uniformly less than T_U. Under such circumstances, the penetration plume flow is not positively (i.e., upward) buoyant at any point as it enters the upper layer. Therefore, while all of this flow is assumed to enter and mix with the upper layer, it is predicted that none of it rises to the ceiling in a coherent plume (i.e., $\dot{Q}' = 0$). For this reason, where $\sigma < 0$, the existence of any significant ceiling jet flow is precluded, along with significant convective heat transfer to the ceiling surface or to near-ceiling–deployed fusible links.

The preceding analysis assumes that $y_{fire} < y$. However, at the onset of the fire scenario, $y_{fire} < y = y_{ceil}$ and α, σ, and $\dot{m}^*$ of Equation B.4.4.1e through Equation B.4.4.1h, which depend on the indeterminate initial value of T_U, are themselves undefined. The situation at $t = 0$ is properly taken into account if $Q = (1\text{-}\lambda_r)\dot{Q}$ and

$$y'_{source} = y_{eq} \quad \text{at } t = 0 \qquad \textbf{[B.4.4.1j]}$$

B.4.4.2 General Properties of the Plume in the Upper Layer. When the fire is below the interface, the results of Equations B.4.4.1i and B.4.4.1j allow the fire-driven plume dynamics in the upper layer to be described according to the point-source plume model [10]. If the fire is at or above the interface (i.e., $y_{fire} \geq y$), then $\dot{m}_{plume} = 0$, $\dot{q}_{plume} = (1 - \lambda_r)\dot{Q}$, and the point-source model is used once again to simulate the upper-layer plume flow. All cases can be treated using the following modified versions of original Equations B.4.4.1i and B.4.4.1j:

$$\dot{Q}' = \left|\begin{array}{ll} \dfrac{(1-\lambda_r)Q\sigma\dot{m}^*}{(1+\sigma)}; & \text{if } y_{fire} < y < y_{ceil} \\ (1-\lambda_r)\dot{Q}; & \text{if } y_{fire} \geq y \quad \text{or} \quad \text{if } y = y_{ceil} \end{array}\right. \qquad \textbf{[B.4.4.2a]}$$

[B.4.4.2b]

$$y'_{source} = \left|\begin{array}{ll} y_{fire;} \quad \text{if } y \leq y_{fire} < y_{ceil} & \\ y - (y - y_{eq})\alpha^{3/5}\dot{m}^{*2/5}\left(\dfrac{1+\sigma}{\sigma}\right)^{1/5}; & \text{if } y_{fire} < y < y_{ceil} \\ y_{eq}; \quad \text{if } y = y_{ceil} & \end{array}\right.$$

where y_{eq}, $\dot{m}^*$, σ, and α are calculated from Equations B.4.4.1c through B.4.4.1g.

B.4.5 Computing $\dot{q}HT$ and the Thermal Response of the Ceiling. Where the fire is below the interface and the interface is below the ceiling, the method used for calculating the heat transfer from the plume-driven ceiling jet to the ceiling and the thermal response of the ceiling is from reference [12]. This method was developed to treat generic, confined-ceiling, room fire scenarios. As outlined in this method [12], the confined ceiling problem is solved by applying the unconfined ceiling heat transfer solution [13–15] to the problem of an upper-layer source in an extended upper-layer environment equivalent to Equations B.4.4.2a and B.4.4.2b. When the fire is about the interface, the unconfined ceiling methodology applies directly.

To use the methods in references [12–15], an arbitrary moment of time during the course of the fire development is considered. It is assumed that the temperature distribution of

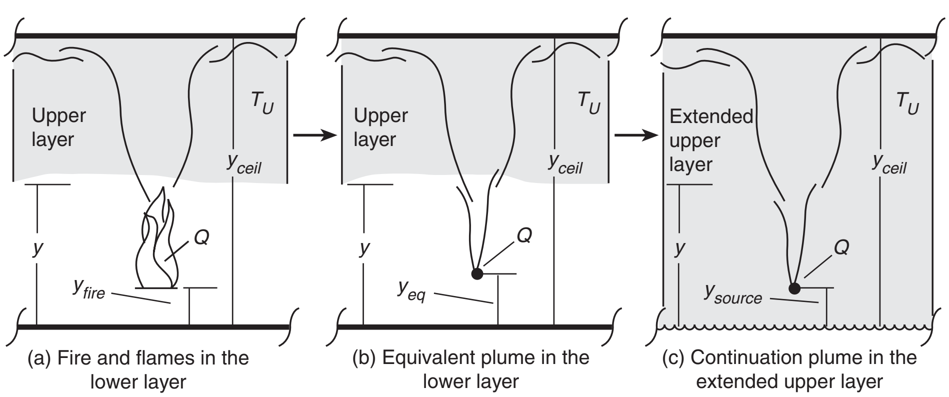

FIGURE B.4.4.1 Fire and Equivalent Source.

the ceiling material, T, has been computed up to this moment and is known as a function of distance, Z, measured upward from the bottom surface of the ceiling, and radial distance, r, measured from the constant point of plume–ceiling impingement. The equivalent, extended upper-layer, unconfined ceiling flow and heat transfer problem is depicted in Figure B.4.4.1. It involves the equivalent $\dot{Q}'$ heat source from Equation B.4.4.2a located a distance, H, below the ceiling surface in an extended ambient environment of density, ρ_U, and absolute temperature, T_U, where H is determined from Equations B.4.4.1h and B.4.4.1j.

The objective is to estimate the instantaneous convective heat transfer flux from the upper-layer gas to the lower-ceiling surface, $\dot{q}''_{conv,L}(r,t)$, and the net heat transfer fluxes to the upper and lower ceiling surface of the ceiling, $\dot{q}''_u(r,t)$ and $\dot{q}''_L(r,t)$, respectively. With this information, the time-dependent solution for the in-depth thermal response of the ceiling material can be advanced to subsequent times. Also, $\dot{q}''_{conv,L}$ can be integrated over the lower-ceiling surface to obtain the desired instantaneous value for $\dot{q}_{HT}$.

In view of the assumptions of the relatively large distance of the fire from walls or curtains and on the relatively small contribution of heat transfer to these vertical surfaces, it is reasonable to carry out a somewhat simplified calculation for $\dot{q}_{HT}$. Therefore, $\dot{q}_{HT}$ is approximated by the integral of $\dot{q}''_{conv,L}$ over an effective circular ceiling area, A_{eff}, with a diameter, D_{eff}, centered at the point of impingement as follows:

$$\begin{aligned}\dot{q}_{HT} &= \lambda_{conv}\dot{Q}(t)\\ &= -\int_A \dot{q}''_{conv,L}(r,t)\,dA\\ &\approx -2\pi\int_0^{D_{eff}/2} \dot{q}''_{conv,L}(r,t)\,r\,dr\end{aligned} \quad \textbf{[B.4.5a]}$$

The value $A_{eff} = \pi D^2_{eff}/4$ is taken to be the actual area of the curtained space, A, plus the portion of the vertical curtain and wall surfaces estimated to be covered by ceiling jet–driven wall flows. An estimate for this extended, effective ceiling surface area is obtained [16], where it is concluded with some generality that ceiling jet–driven wall flows penetrate for a distance of approximately $0.8H$ from the ceiling in a downward direction. Therefore,

$$\begin{aligned}A_{eff} &= \frac{\pi D^2_{eff}}{4}\\ &= A + 0.8H\left(P - L_{curt}\right) + L_{curt}\min\left[0.8H,\left(y_{ceil} - y_{curt}\right)\right]\end{aligned} \quad \textbf{[B.4.5b]}$$

where P = the total length of the perimeter of the curtained area.

B.4.5.1 Net Heat Transfer Flux to the Ceiling's Lower Surface. The net heat transfer flux to the ceiling's lower surface, $\dot{q}''_L$, is made by means of up to three components — incident radiation, $\dot{q}''_{rad-fire}$; convection, $\dot{q}''_{conv,L}$; and reradiation, $\dot{q}''_{rerad,L}$ — as follows:

$$\dot{q}''_L = \dot{q}''_{rad-fire} + \dot{q}''_{conv,L} + \dot{q}''_{rerad,L} \quad \textbf{[B.4.5.1a]}$$

As discussed in B.4.4, the radiant energy from the fire, $\lambda_r\dot{Q}$, is assumed to be radiated isotropically from the fire with negligible radiation absorption and emission from the compartment gases.

$$\dot{q}''_{rad-fire} = \left[\frac{\lambda_r\dot{Q}}{4\pi\left(y_{ceil} - y_{fire}\right)^2}\right]\left[1 + \left(\frac{r}{y_{ceil} - y_{fire}}\right)^2\right]^{-3/2} \quad \textbf{[B.4.5.1b]}$$

The convective heat transfer flux from the upper-layer gas to the ceiling's lower surface can be calculated [13, 14] as follows:

$$\dot{q}''_{conv,L} = h_L\left(T_{AD} - T_{S,L}\right) \quad \textbf{[B.4.5.1c]}$$

where:

$\dot{q}''_{conv,L}$ = convective heat transfer flux from the upper-layer gas to the ceiling's lower surface

h_L = a heat transfer coefficient

T_{AD} = the temperature that is measured adjacent to an adiabatic lower-ceiling surface

$T_{S,L}$ = the absolute temperature of the ceiling's lower surface

Equations B.4.5.1d and B.4.5.1e determine h_L and T_{AD} as follows:

$$\frac{h_L}{\tilde{h}} = \begin{cases} 8.82Re_H^{-1/2}Pr^{-2/3}\left[1 - \left(5.0 - 0.284Re_H^{0.2}\right)\left(\dfrac{r}{H}\right)\right]; & \text{if } 0 \le \dfrac{r}{H} < 0.2 \\ 0.283Re_H^{-0.3}Pr^{-2/3}\left(\dfrac{r}{H}\right)^{-1/2}\left(\dfrac{\dfrac{r}{H} - 0.0771}{\dfrac{r}{H} + 0.279}\right); & \text{if } 0.2 \le \dfrac{r}{H} \end{cases} \quad \textbf{[B.4.5.1d]}$$

$$\frac{T_{AD} - T_U}{T_U\dot{Q}_H^{*2/3}} = \begin{cases} 10.22 - \dfrac{14.9r}{H}; & \text{if } 0 \le \dfrac{r}{H} < 0.2 \\ 8.39f\left(\dfrac{r}{H}\right); & \text{if } 0.2 \le \dfrac{r}{H} \end{cases} \quad \textbf{[B.4.5.1e]}$$

where:

[B.4.5.1f]

$$f\left(\frac{r}{H}\right) = \frac{1 - 1.10\left(\dfrac{r}{H}\right)^{0.8} + 0.808\left(\dfrac{r}{H}\right)^{1.6}}{1 - 1.10\left(\dfrac{r}{H}\right)^{0.8} + 2.20\left(\dfrac{r}{H}\right)^{1.6} + 0.690\left(\dfrac{r}{H}\right)^{2.4}}$$

$$\tilde{h} = \rho_U C_p g^{1/2} H^{1/2} \dot{Q}_H^{*1/3}$$

$$Re_H = \frac{g^{1/2}H^{3/2}\dot{Q}_H^{*1/3}}{\nu_U} \quad \textbf{[B.4.5.1g]}$$

$$\dot{Q}_H^* = \frac{\dot{Q}'}{\rho_U C_p T_U (gH)^{1/2} H^2}$$

In Equation B.4.5.1d, Pr is the Prandtl number (taken to be 0.7), and in Equation B.4.5.1g, ν_U is the kinematic viscosity of the upper-layer gas, which is assumed to have the properties of air. Also, $\dot{Q}_H^*$, a dimensionless number, is a measure of the strength of the plume, and Re_H is a characteristic Reynolds number of the plume at the elevation of the ceiling.

The following estimate for ν_U [17] is used when computing Re_H from Equation B.4.5.1g:

$$\nu_U = \frac{0.04128\left(10^{-7}\right)T_U^{5/2}}{T_U + 110.4} \quad \textbf{[B.4.5.1h]}$$

where ν_U is in m^2/s and T_U is in K.

Equations B.4.5.1c through B.4.5.1h use a value for T_U. At $t = 0$, where it is undefined, T_U should be set equal to T_{amb}. This yields the correct limiting result for the convective heat transfer to the ceiling, specifically, convective heat transfer to the initially ambient temperature ceiling from an unconfined ceiling jet in an ambient environment.

As the fire simulation proceeds, the ceiling's lower surface temperature, $T_{S,L}$, initially at T_{amb}, begins to increase. At all times, the lower-ceiling surface is assumed to radiate diffusely to the initially ambient temperature floor surface and to exposed surfaces of the building contents. In response to this radiation and to the direct radiation from the fire's combustion zone, the temperatures of these surfaces also increase with time. However, for times of interest here, it is assumed that their effective temperature increases are relatively small compared to the characteristic increases of $T_{S,L}$. Accordingly, at a given radial position of the ceiling's lower surface, the net radiation exchange between the ceiling and floor-contents surfaces can be approximated by the following:

$$\dot{q}''_{rerad,L} = \frac{\sigma\left(T_{amb}^4 - T_{S,L}^4\right)}{\dfrac{1}{\epsilon_L} + \dfrac{1}{\epsilon_{floor}} - 1} \quad \textbf{[B.4.5.1i]}$$

where σ is the Stefan–Boltzmann constant and ϵ_L and ϵ_{floor} are the effective emittance-absorptance of the ceiling's lower surface and the floor and contents surfaces (assumed to be gray), respectively, both of which are taken to be 1.

B.4.5.2 Net Heat Transfer Flux to Ceiling's Upper Surface. It is assumed that the ceiling's upper surface is exposed to a relatively constant-temperature far-field environment at T_{amb}. Therefore, the net heat transfer flux to this surface, $\dot{q}_U$, is made up of two components, convection, $\dot{q}''_{conv,U}$, and reradiation, $\dot{q}''_{rerad,U}$, as follows:

$$q''_U = \dot{q}''_{conv,U} + \dot{q}''_{rerad,U} \quad \textbf{[B.4.5.2a]}$$

These can be estimated from the following:

$$\dot{q}''_{conv,U} = h_U\left(T_{amb} - T_{S,U}\right) \quad \textbf{[B.4.5.2b]}$$

$$\dot{q}''_{rerad,U} = \frac{\sigma\left(T_{amb}^4 - T_{S,U}^4\right)}{\dfrac{1}{\epsilon_U} + \dfrac{1}{\epsilon_{far}} - 1} \quad \textbf{[B.4.5.2c]}$$

where $T_{S,U}$ is the absolute temperature of the upper surface of the ceiling, h_U is a heat transfer coefficient, and ϵ_{far} and ϵ_U are the effective emittance-absorptance of the far-field and ceiling's upper surface (assumed to be gray), respectively, both of which are taken to be 1.

The value for h_U to be used [18] is as follows:

$$h_U = 1.65\left(T_{amb} - T_{S,U}\right)^{1/3} \quad \textbf{[B.4.5.2d]}$$

where h_U is in W/m^2, and T_{amb} and $T_{S,U}$ are in K.

B.4.5.3 Solving for the Thermal Response of the Ceiling for $\dot{q}_{HT}$. The temperature of the ceiling material is assumed to be governed by the Fourier heat conduction equation. By way of the lower-ceiling-surface boundary condition, the boundary value problem is coupled to, and is to be solved together with, the system of Equations B.3b and B.3h.

Initially, the ceiling is taken to be of uniform temperature, T_{amb}. The upper- and lower-ceiling surfaces are then exposed to the radial- and time-dependent rates of heat transfer, $\dot{q}''_U$ and $\dot{q}''_L$, determined from Equations B.4.5.2a and B.4.5.1a, respectively. For times of interest here, radial gradients of $\dot{q}''_U$ and $\dot{q}''_L$ are assumed to be small enough so that conduction in the ceiling is quasi-one-dimensional in space [i.e., $T = T(Z, t; r)$]. Therefore, the two-dimensional thermal response for the ceiling can be obtained from the solution to a set of one-dimensional conduction problems for the following:

$$T_n(Z,t) = T(Z,t; r = r_n); \quad n = 1 \text{ to } N_{rad} \quad \textbf{[B.4.5.3a]}$$

where N_{rad} is the number of discrete radial positions necessary to obtain a sufficiently smooth representation of the overall ceiling temperature distribution. The r_n radial positions are depicted in Figure B.4.5.3.

Characteristic changes in ceiling temperature will occur over changes in r/H of the order of 1 [15]. Therefore, it is reasonable to expect accurate results for the Equation B.4.5a integral $\dot{q}''_{conv,L}$ by interpolating between values of $\dot{q}''_{conv,L}$ calculated at radial positions separated by r/H intervals of 0.1 to 0.2.

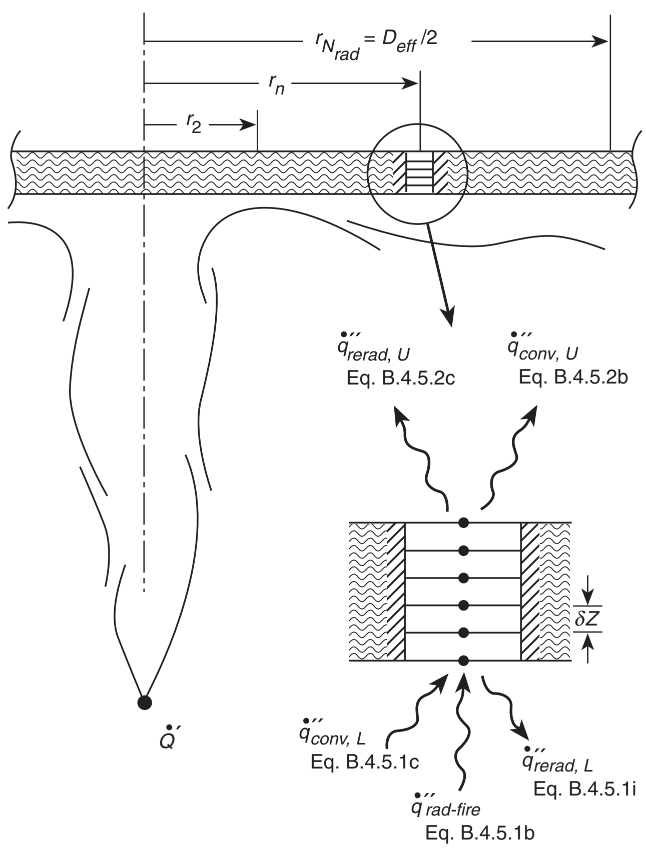

FIGURE B.4.5.3 Illustration of the Geometry for the Boundary Value Problems of the Temperature Distributions, T_n, Through the Ceiling at Radial Positions r_n.

Using the preceding ideas, the following procedure for finding the thermal response of the ceiling and solving for $\dot{q}''_{HT}$ is implemented:

(1) Because $y_{ceil} - y_{fire}$ is a measure of H in the current problem and $D_{eff}/2$ is a measure of the maximum value of r, N_{rad} is chosen as several multiples of the following:

$$\frac{D_{eff}/2}{y_{ceil} - y_{fire}} \qquad \textbf{[B.4.5.3(b)]}$$

In this case, N_{rad} is chosen as the first integer equal to or greater than the following:

$$\frac{5\left(D_{eff}/2\right)}{y_{ceil} - y_{fire}} + 2 \qquad \textbf{[B.4.5.3(c)]}$$

(2) One temperature calculation point is placed at $r = 0$ and the remaining N_{rad} calculation points are distributed with uniform separation at and between $r = 0.2(y_{ceil} - y_{fire})$ and $r = D_{eff}/2$, the latter value being the upper limit of the integral of Equation B.4.5a; that is,

$$\begin{aligned} r_1 &= 0 \\ r_2 &= 0.2\left(y_{ceil} - y_{fire}\right) \\ r_{N_{rad}} &= \frac{D_{eff}}{2} \\ r_n &= r_{n-1} + \Delta r \quad \text{if } 2 < n < N_{rad} \end{aligned} \qquad \textbf{[B.4.5.3(d)]}$$

where

$$\Delta r = \left(r_{N_{rad}} - r_2\right) \big/ \left(N_{rad} - 3\right) \qquad \textbf{[B.4.5.3(e)]}$$

(3) The boundary value problems are solved for the N_{rad} temperature distributions, T_n. At arbitrary radius, r_n, these are indicated in the inset portion of Figure B.4.5.3.

(4) For any moment of time during the calculation, the lower surface values of the T_n are used to compute the corresponding discrete values of

$$\dot{q}''_{conv,L,n}(t) = \dot{q}''_{conv,L}(r = r_n, t) \qquad \textbf{[B.4.5.3(f)]}$$

from Equation B.4.5.1c.

(5) The $\dot{q}''_{conv,L}$ distribution in r is approximated by interpolating linearly between the $\dot{q}''_{conv,L,n}$. The integration indicated in Equation B.4.5a is carried out.

The procedure for solving for the T_n is the same as that used in reference [15]. It requires the thickness, thermal conductivity, and thermal diffusivity of the ceiling material. The solution to the one-dimensional heat conduction equation involves an explicit finite difference scheme that uses an algorithm taken from references [19, 20]. For a given set of calculations, $N \leq 20$ equal-spaced nodes are positioned at the surfaces and through the thickness of the ceiling at every radius position, r_n. The spacing, δZ *(see Figure B.4.5.3)*, of these is selected to be large enough (based on a maximum time step) to ensure stability of the calculation.

B.5 Actuation of Vents and Sprinklers. It is an objective of this standard to simulate conditions in building spaces where ceiling vents and sprinkler links can be actuated by the responses of near-ceiling–deployed fusible links. The concept is that, during the course of a compartment fire, a deployed link is engulfed by the near-ceiling convective flow of the elevated-temperature products of combustion and entrained air of the fire-generated plume. As the fire continues, convective heating of the link leads to an increase in its temperature. If and when its fuse temperature is reached, any devices being operated by the link are actuated.

The near-ceiling flow engulfing the link is the plume-driven ceiling jet referred to previously, which transfers heat to the lower-ceiling surface and is cooled as it traverses under the ceiling from the point of plume–ceiling impingement. In the case of relatively smooth ceiling configurations, assumed to be representative of the facilities studied in this standard, the ceiling jet flows outward radially from the point of impingement, and its gas velocity and temperature distributions, V_{CJ} and T_{CJ}, respectively, are a function of radius from the impingement point, r, distance below the ceiling, z, and time, t.

Vents actuated by alternate means, such as thermoplastic drop-out panels with equivalent performance characteristics, can also be modeled using LAVENT. Refer to A.9.1.

B.5.1 Predicting the Thermal Response of the Fusible Links. The thermal response of deployed fusible links is calculated up to their fuse temperature, T_F, by the convective heating flow model of reference [21]. It is assumed that the specific link is positioned at a specified radius from the impingement point, $r = r_L$, and distance below the lower-ceiling surface, $z = z_L$. T_L is defined as the link's assumed, nearly uniform temperature. Instantaneous changes in T_L are determined by the following:

$$\frac{dT_L}{dt} = \frac{\left(T_{CJ,L} - T_L\right)V_{CJ,L}^{1/2}}{RTI} \qquad \textbf{[B.5.1]}$$

where $T_{CJ,L}$ and $V_{CJ,L}$ are the values of V_{CJ} and T_{CJ}, respectively, evaluated near the link position, and where *RTI* (response time index), a property of the link and relative flow orientation, can be measured in the "plunge test" [21, 22]. The *RTI* for ordinary sprinkler links ranges from low values of 22 $(\text{m}\cdot\text{s})^{1/2}$ for quick-operating residential sprinklers, to 375 $(\text{m}\cdot\text{s})^{1/2}$ for slower standard sprinklers [23]. The utility of Equation B.5.1, which has been shown in reference [24] to be valid typically through the link-fusing processes, is discussed further in reference [23], where it was used to predict link response in a parametric study involving two-layer compartment fire scenarios. Also, in the latter work, the link response prediction methodology was shown to demonstrate favorable comparisons between predicted and measured link responses in a full-scale, one-room, open-doorway compartment fire experiment.

Computing T_L from Equation B.5.1 for a different link location necessitates estimates of $V_{CJ,L}$ and $T_{CJ,L}$ for arbitrary link positions, r_L and z_L.

B.5.2 The Velocity Distributions of the Ceiling Jet. Outside of the plume–ceiling impingement stagnation zone, defined approximately by $r/H \leq 0.2$, and at a given r, V_{CJ} rises rapidly from zero at the ceiling's lower surface, $z = 0$, to a maximum, V_{max}, at a distance $z = 0.23\delta$, $\delta(r)$ being the distance below the ceiling where $V/V_{max} = 1/2$ [16]. In this region outside the stagnation zone, V_{CJ} can be estimated [16] as follows:

$$\text{if } \frac{r}{H} \geq 0.2; \qquad \textbf{[B.5.2a]}$$

$$\frac{V_{CJ}}{V_{max}} = \begin{cases} \left(\dfrac{8}{7}\right)\left(\dfrac{z}{0.23\delta}\right)^{1/7}\left[1 - \dfrac{z/(0.23\delta)}{8}\right]; & \text{if } 0 \leq \dfrac{z}{0.23\delta} \leq 1 \\ \cosh^{-2}\left\{\left(\dfrac{0.23}{0.77}\right)\operatorname{arccosh}\left(2^{1/2}\right) \times \left[\dfrac{z}{0.23\delta} - 1\right]\right\}; & \text{if } 1 \leq \dfrac{z}{0.23\delta} \end{cases}$$

$$\frac{V_{max}}{V} = 0.85\left(\frac{r}{H}\right)^{-1.1}$$
$$\frac{\delta}{H} = 0.10\left(\frac{r}{H}\right)^{0.9} \quad \textbf{[B.5.2b]}$$
$$V = g^{1/2}H^{1/2}\dot{Q}_H^{*1/3}$$

where $\dot{Q}_H^*$ is defined in Equation B.4.5.1g. V_{CJ}/V_{max} per Equation B.5.2a is plotted in Figure B.5.2.

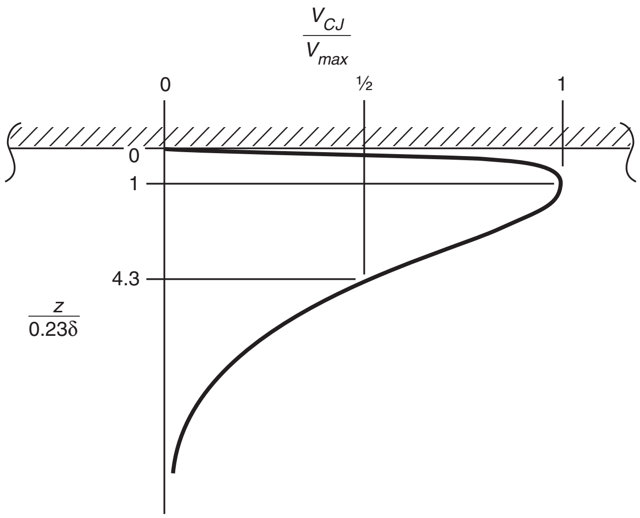

FIGURE B.5.2 A Plot of Dimensionless Ceiling Jet Velocity Distribution, V_{CJ}/V_{max}, as a Function of $z/0.23\delta$ per Equation B.5.2a.

In the vicinity of near-ceiling–deployed links located inside the stagnation zone, the fire-driven flow is changing directions from an upward-directed plume flow to an outward-directed ceiling jet–type flow. There the flow velocity local to the link, the velocity that drives the link's connective heat transfer, involves generally a significant vertical as well as radial component of velocity. Nevertheless, at such link locations, it is reasonable to continue to approximate the link response using Equation B.5.1 with V_{CJ} estimated using Equations B.5.2a and B.5.2b and with r/H set equal to 0.2; that is,

$$V_{CJ} = V_{CJ}\left(\frac{r}{H} = 0.2\right); \quad \text{if } 0 \le \frac{r}{H} < 0.2 \qquad \textbf{[B.5.2c]}$$

B.5.3 The Temperature Distribution of the Ceiling Jet. Outside of the plume–ceiling impingement stagnation zone (i.e., where $r/H \ge 0.2$) and at a given value of r, T_{CJ} rises very rapidly from the temperature of the ceiling's lower surface, $T_{S,L}$, at $z = 0$, to a maximum, T_{max}, somewhat below the ceiling surface. It is assumed that this maximum value of T_{CJ} occurs at the identical distance below the ceiling as does the maximum of V_{CJ} (i.e., at $z = 0.23\delta$). Below this elevation, T_{CJ} drops with increasing distance from the ceiling until it reaches the upper-layer temperature, T_U. In this latter, outer region of the ceiling jet, the shape of the normalized T_{CJ} distribution, $(T_{CJ} - T_U)/(T_{max} - T_U)$, has the same characteristics as that of V_{CJ}/V_{max}. Also, because the boundary flow is turbulent, it is reasonable to estimate the characteristic thicknesses of the outer region of both the velocity and temperature distributions as being identical, both dictated by the distribution of the turbulent eddies there.

For these reasons, the dimensionless velocity and temperature distribution are approximated as being identical in the outer region of the ceiling jet flow, $0.23\delta \le z$. In the inner region of the flow, between $z = 0$ and 0.23δ, the normalized temperature distribution is approximated by a quadratic function of $z/(0.23\delta)$, with $T_{CJ} = T_{S,L}$ at $z = 0$ and $T_{CJ} = T_{max}$, $dT_{CJ}/dz = 0$ at $z = 0.23\delta$. Therefore, where $r/H \ge 0.2$,

[B.5.3a]

$$\Theta \equiv \frac{T_{CJ} - T_U}{T_{max} - T_U} = \begin{cases} \Theta_S + 2\left[(1-\Theta_S)\left(\dfrac{z}{0.23\delta}\right)\right] - \left[(1-\Theta_S)\left(\dfrac{z}{0.23\delta}\right)^2\right]; \\ \quad \text{if } 0 \le \dfrac{z}{0.23\delta} \le 1 \\ \dfrac{V_{CJ}}{V_{max}}; \ \text{if } 1 \le \dfrac{z}{0.23\delta} \end{cases}$$

$$\Theta_S \equiv \Theta\left(T_{CJ} = T_{S,L}\right) = \frac{T_{S,L} - T_U}{T_{max} - T_U} \qquad \textbf{[B.5.3b]}$$

It should be noted that Θ_S is negative when the ceiling surface temperature is less than the upper-layer temperature (e.g., relatively early in a fire, when the original ambient-temperature ceiling surface has not yet reached the average temperature of the growing upper layer). Also, Θ_S is greater than 1 when the ceiling surface temperature is greater than T_{max}. This is possible, for example, during times of reduced fire size when the fire's near-ceiling plume temperature is reduced significantly, perhaps temporarily, from previous values, but the ceiling surface, heated previously to relatively high temperatures, has not cooled substantially. Plots of Θ per Equation B.5.3a are shown in Figure B.5.3 for cases where Θ is < 0, between 0 and 1, and > 0.

In a manner similar to the treatment of V_{CJ}/V_{max}, for the purpose of calculating T_L, from Equation B.5.1, Θ_S is approximated

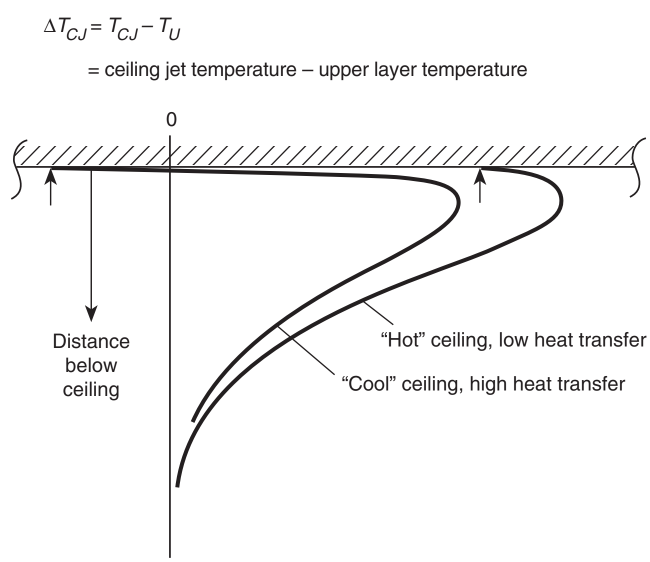

FIGURE B.5.3 Plots of Dimensionless Ceiling Jet Temperature Distribution, Θ, as a Function of $z/0.23\delta$ per Equation B.5.3a for Cases Where Θ_S is <0, Between 0 and 1, and >0.

inside the stagnation zone by the description of Equations B.5.3a and B.5.3b, with r/H set equal to 0.2 as follows:

$$\Theta_S = \Theta_S\left(\frac{r}{H} = 0.2\right); \quad \text{if } 0 \le \frac{r}{H} \le 0.2 \qquad \textbf{[B.5.3c]}$$

With the radial distribution for $T_{S,L}$ and T_U already calculated up to a specific time, only T_{max} is needed to complete the derived estimate from Equations B.5.3a through B.5.3c for the ceiling jet temperature distribution. This estimate is obtained by invoking conservation of energy. Therefore, at an arbitrary r outside the stagnation zone, the total rate of radial outflow of enthalpy (relative to the upper-layer temperature) of the ceiling jet is equal to the uniform rate of enthalpy flow in the upper-layer portion of the plume, $\dot{Q}'$, less the integral (from the plume–ceiling impingement prior to r) of the flux of convective heat transfer from the ceiling jet to the ceiling surface as follows:

$$2\pi\int_0^\infty \rho_U C_P \left(T_{CJ} - T_U\right) V_{CJ} r \, dz = \dot{Q}' - 2\pi\int_0^r \dot{q}''_{conv,L}(r,t)\, r\, dr \qquad \textbf{[B.5.3d]}$$
$$\equiv \left(1 - \lambda'_{conv}\right) \dot{Q}'; \quad \text{if } 0.2 \le \frac{r}{H}$$

λ'_{conv} is the fraction of $\dot{Q}'$ transferred by convection to the ceiling from the point of ceiling impingement to r as follows:

$$\lambda'_{conv}(r) = \frac{2\pi\int_0^r \dot{q}''_{conv,L}(r,t)\, r\, dr}{\dot{Q}'} \qquad \textbf{[B.5.3e]}$$

In Equations B.5.3d and B.5.3e, $\dot{Q}'$ has been calculated previously in Equation B.4.4.2a. Also, the integral on the right-hand sides of Equations B.5.3d and B.5.3e can be calculated by approximating $\dot{q}''_{conv,L}(r,t)$, as shown in Equation B.5.3e, as a linear function of r between previously calculated values of $\dot{q}_{conv,L}\left(r = r_n, t\right)$.

The integral on the left-hand side of Equation B.5.3d is calculated using V_{CJ} of Equations B.5.2a and B.5.3b and T_{CJ} of Equations B.5.3a and B.5.3b. From this, the desired distribution for T_{max} is determined as follows:

[B.5.3f]

$$\left(T_{max} - T_U\right) = 2.6\left(1 - \lambda'_{conv}\right)\left(\frac{r}{H}\right)^{-0.8} \dot{Q}_H^{*2/3} T_U - 0.090\left(T_{S,L} - T_U\right);$$
$$\text{if } 0.2 \le \frac{r}{H}$$

The result of Equation B.5.3f, together with Equations B.5.3a and B.5.3b, represents the desired estimate for T_{CJ}. This and the estimate derived from Equations B.5.2a through B.5.2c for T_{CJ} are used to calculate T_L from Equation B.5.1.

B.5.4 Dependence of Open Vent Area on Fusible-Link–Actuated Vents. As discussed, the influence of ceiling vent action on the fire-generated equipment is dependent on the active area of the open ceiling vents, A_V. A variety of basic vent opening design strategies is possible, and a major application of the current model equations is to evaluate these strategies within the context of the developing fire environment. For example, one of the simplest strategies [9] assumes that all vents deployed in the specified curtained area are opened by whatever means at the onset of the fire. In general, A_V will be time-dependent. To the extent that a strategy of vent opening is dependent directly on the fusing of any one or several deployed fusible links, the location of these links and their characteristics (i.e., likely spacings from plume–ceiling impingement, distance below the ceiling, and the RTI) and the functional relationship between link fusing and A_V need to be specified. These matters can be examined in the context of different solutions to the overall problem by exercising parametrically the LAVENT computer program [2], which implements all the model equations provided in this annex.

B.5.5 Concluding Remarks — A Summary of Guidelines, Assumptions, and Limitations. The theory presented here is the basis of LAVENT, a user-friendly computer program [2] that is supported by a user guide [3] and that can be used to study parametrically a wide range of relevant fire scenarios.

The assumptions made in the development of the set of model equations limit fire scenarios or aspects of fire scenarios that can be simulated and studied with confidence. A summary of guidelines and assumptions that characterize what are perhaps the most critical of these limitations follows. These are the result of explicit or implicit assumptions necessary for valid application of the variety of submodels introduced throughout this work.

L and W are the length and width, respectively, of the plan area of the curtained space. Simulated configurations should be limited to those with aspect ratios, L/W, that are not much different from 1 (e.g., $0.5 \le L/W < 2$). Also, in such configurations, the fire should not be too close to or too far from the walls [e.g., the fire should be no closer to a wall than $(y_{ceil} - y_{fire})/2$ and no farther than $3(y_{ceil} - y_{fire})$].

The curtain boards should be deep enough to satisfy $(y_{ceil} - y_{curt}) \le 0.2\ (y_{ceil} - y_{fire})$, unless the equations and the standard are used to simulate an unconfined ceiling scenario where $(y_{ceil} - y_{curt}) = 0$.

The ceiling of the curtained space should be relatively smooth, with protuberances having depths significantly less than $0.1(y_{ceil} - y_{fire})$. Except at the locations of the curtain boards, below-ceiling–mounted barriers to flow, such as solid beams, should be avoided. Ceiling surface protuberances near to and upstream of fusible links (i.e., between the links and the fire) should be significantly smaller than link-to-ceiling distances.

W_V is the width, that is, the smaller dimension of a single ceiling vent (or vent cluster). If vents are open, the prediction of smoke layer thickness, $y_{ceil} - y$, is reliable only after the time that $(y_{ceil} - y)/W_V$ is greater than 1. (For smaller layer depths, "plugholing" flow through the vents could occur, leading to possible significant inaccuracies in vent flow estimates.) Note that this places an additional limitation on the minimum depth of the curtain boards [i.e., $(y_{ceil} - y_{curt})/W_V$ should exceed 1].

At all times during a simulated fire scenario, the overall building space should be vented to the outside (e.g., through open doorways).

In this regard, compared to the open ceiling vents in the curtained compartment, the area of the outside vents must be large enough such that the pressure drop across the outside vents is small compared to the pressure drop across ceiling vents. For example, under near-steady-state conditions, when the rate of mass flow into the outside vents is approximately equal to the rate of mass outflow from the ceiling vents, the outside vent area must satisfy $(A_{Vout}/A_V)^2(T_U/T_{amb})^2 >> 1$, or, more conservatively and independent of T_U, $(A_{Vout}/A_V)^2 >> 1$. The latter criterion will always be reasonably satisfied if $A_{Vout}/A_V > 2$. Under flashover-level conditions — say, when $T_U / T_{amb} = 3$ — the former criterion will be satisfied if $(3A_{Vout}/A_V)^2 >> 1$ — say, if $A_{Vout} = A_V$, or even if A_{Vout} is somewhat smaller than A_V.

The simulation assumes a relatively quiescent outside environment (i.e., without any wind) and a relatively quiescent inside environment (i.e., remote from vent flows, undercurtain flows, ceiling jets, and the fire plume). In real fire scenarios, such an assumption should be valid where the characteristic velocities of actual flows in these quiescent environments are much less than the velocity of the fire plume near its ceiling impingement point (i.e., where the characteristic velocities are much less than V_{max} of Equation B.5.2b). It should be noted that, for a given fire strength, Q, this latter assumption places a restriction on the maximum size of $(y_{ceil} - y_{fire})$, which is a measure of H, since V_{max} is approximately proportional to $(y_{ceil} - y_{fire})^{-1/3}$.

In configurations where smoke flows below curtain partitions to adjacent curtained spaces, the simulation is valid only up to the time that it takes for any one of the adjacent spaces to fill with smoke to the level of the bottom of the curtain. While it is beyond the scope of this standard to provide any general guidelines for this limiting time, the following rule can be useful where all curtained spaces of a building are similar and where the fire is not growing too rapidly: The time to fill an adjacent space is of the order of the time to fill the original space.

The reliability of the simulation begins to degrade subsequent to the time that the top of the flame penetrates the layer elevation, and especially if Equation B.4.3a predicts a flame height that reaches the ceiling.

It is assumed that the smoke is relatively transparent and that the rate of radiation absorbed by or emitted from the smoke layer is small compared to the rate of radiation transfer from the fire's combustion zone. The assumption is typically true, and a simulation is valid at least up to those times that the physical features of the ceiling can be discerned visually from the floor elevation.

It should be emphasized that the preceding limitations are intended only as guidelines. Therefore, even when the characteristics of a particular fire scenario satisfy these limitations, the results should be regarded with caution until solutions to the overall model equations have been validated by a substantial body of experimental data. Also, where a fire scenario does not satisfy the preceding limitations but is close to doing so, it is possible that the model equations can still provide useful quantitative descriptions of the simulated phenomena.

B.7 Nomenclature for Annex B.

A = plan area of single curtain space

A_{eff} = effective area for heat transfer to the extended lower-ceiling surface, $\pi D_{eff}^2 / 4$

A_V = total area of open ceiling vents in curtained space

A_{Vout} = total area of open vents to outside exclusive of A_V

C = vent flow coefficient (0.68)

C_P = specific heat at constant pressure

C_T = 9.115, dimensionless constant in plume model

C_V = specific heat at constant volume

D_{eff} = effective diameter of A_{eff}

D_{fire} = effective diameter of fire source ($\pi D_{fire}^2/4$ = area of fire source)

g = acceleration of gravity

H = distance below ceiling of equivalent source

$\tilde{h}$ = characteristic heat transfer coefficient

h_L, h_U = lower-, upper-ceiling surface heat transfer coefficient

L = characteristic length of the plan area of curtained space

L_{curt} = length of the perimeter of A connected to other curtained areas of the building

L_{flame} = flame length

$\dot{m}_{curt}$ = mass flow rate from below curtain to upper layer

$\dot{m}_{ent}$ = rate of plume mass entrainment between the fire and the layer interface

$\dot{m}_{plume}$ = mass flow rate of plume at interface

m_U = total mass of the upper layer

$\dot{m}_U$ = net mass flow rate to upper layer

$\dot{m}_{vent}$ = mass flow rate through ceiling vents to upper layer

N = number of equal-spaced nodes through the ceiling

N_{rad} = number of values of r_n

P = length of perimeter of single curtained area

Pr = Prandtl number, taken to be 0.7

p = pressure

p_U, p_{amb} = pressure in upper-layer, outside ambient

$\dot{Q}$ = energy release rate of fire

$\dot{Q}'$ = strength of continuation source in extended upper layer

$\dot{Q}_H^*$ = dimensionless strength of plume at ceiling

$\dot{Q}_{eq}^*$ = dimensionless strength of plume at interface

$\dot{q}''_{conv,L}, \dot{q}''_{conv,U}$ = convective heat transfer flux to lower-, upper-ceiling surface

$$\dot{q}''_{conv,L,_N} = \dot{q}''_{conv,L}(r = r_n, t)$$

$\dot{q}_{curt}$ = enthalpy flow rate from below curtain to upper layer

$\dot{q}_{HT}$ = heat transfer rate to upper layer

$\dot{q}_{plume}$ = enthalpy flow rate of plume at interface

$\dot{q}_{rad\text{-}fire}$ = radiation flux incident on lower surface of ceiling

$\dot{q}''_{rerad,L}, \dot{q}''_{rerad,U}$ = reradiation flux to lower, upper surface of ceiling

$\dot{q}_U$ = net enthalpy flow rate plus heat transfer rate to upper layer

$\dot{q}'_L, \dot{q}''_U$ = net heat transfer fluxes to upper-, lower-ceiling surface

$\dot{q}_{vent}$ = enthalpy flow rate through ceiling vent to upper layer

R = gas constant, $C_P - C_V$

Re_H = Reynolds number of plume at ceiling elevation

RTI = response time index

r = radial distance from plume–ceiling impingement

r_L = r at link

r_n = discrete values of r

T = absolute temperature of ceiling material

T_{AD} = adiabatic lower-ceiling surface temperature

T_{CJ} = temperature distribution of ceiling jet gas

$T_{CJ,L}$ = T_{CJ} at link

$T_{max}(t) = T_{S,L}(r = 0, t) = T(Z = 0, t, r = 0)$

$T_{S,L}$, $T_{S,U}$ = absolute temperature of lower-, upper-ceiling surface

$T_{S,L,n}(t) = T_{S,L}(r = r_n, t) = T_n(Z = 0, t, r = r_n)$

T_U, T_{amb} = absolute temperature of upper-layer, outside ambient

$T_n = T(Z, t\ r = r_n)$

t = time

V = average flow velocity through all open vents

V = characteristic value of V_{CJ}

V_{CJ} = velocity distribution of ceiling jet gas

$V_{CJ,L}$ = V_{CJ} at link

V_{max} = maximum value of V_{CJ} at a given r

W = characteristic width of plan area of curtained space

W_V = width of a single ceiling vent (or vent cluster)

y, y_{ceil}, y_{curt}, y_{eq}, y_{fire} = elevation of smoke layer interface, ceiling, bottom of curtain, equivalent source fire above floor

y'_{source} = elevation of plume continuation point source in extended upper layer above floor

Z = distance into the ceiling, measured from bottom surface

z, z_L = distance below lower-ceiling surface, z, at link

$\alpha = T_U/T_{amb}$

τ = ratio of specific heat, C_P/C_V

Δp_{ceil} = cross-vent pressure difference

Δp_{curt} = cross-curtain pressure difference

δ = value of z where $V_{CJ} = V_{max}/2$

δZ = distance between nodes through the ceiling thickness

$\in$ = constant, Equations B.4.2c and B.4.2e

$\in_L$, $\in_U$, $\in_{floor}$, $\in_{far}$ = emittance-absorptance of lower, upper, floor, and far-field gray surfaces, all taken to be 1

Θ = normalized, dimensionless ceiling jet temperature distribution, $(T_{CJ} - T_U)/(T_{max} - T_U)$

Θ_S = Θ at lower-ceiling surface, $(T_{S,L} - T_U)/(T_{max} - T_U)$

λ_r = fraction of $\dot{Q}$ radiated from combustion zone

λ_{conv} = fraction of $\dot{Q}$ transferred by convection from upper layer

λ'_{conv} = fraction of $\dot{Q}'$ transferred to the ceiling in a circle of radius, r, and centered at $r = 0$, Equation B.5.3e

ν_U = kinematic viscosity of upper-layer gas

ρ_U, ρ_{amb} = density of upper-layer, outside ambient

σ = dimensionless variable, Equation B.4.4.1e

Annex C User Guide for the LAVENT Computer Code

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

C.1 Overview. This annex is a user guide for the LAVENT computer code (Link-Actuated VENTs), Version 1.1, and an associated graphics code called GRAPH. As discussed in Section 9.3 and in Annex B, LAVENT has been developed to simulate the environment and the response of sprinkler links in compartment fires with curtain boards and fusible-link–actuated ceiling vents. Vents actuated by alternative means such as thermoplastic drop-out panels with equivalent performance characteristics can also be modeled using LAVENT. Refer to A.1.1.1.

A fire scenario simulated by LAVENT is defined by the following input parameters:

(1) Area and height of the curtained space
(2) Separation distance from the floor to the bottom of the curtain
(3) Length of the curtain (A portion of the perimeter of the curtained space can include floor-to-ceiling walls.)
(4) Thickness and properties of the ceiling material (density, thermal conductivity, and heat capacity)
(5) Constants that define a specified time-dependent energy release rate of the fire
(6) Fire elevation
(7) Area or characteristic energy release rate per unit area of the fire
(8) Total area of ceiling vents whose openings are actuated by a single fusible link (Multiple vent area/link system combinations may be permitted in any particular simulation.)
(9) Identifying numbers of fusible links used to actuate single sprinkler heads or groups of sprinkler heads (Multiple sprinkler links are permitted in any particular simulation.)

The characteristics of the simulated fusible links are defined by the following input parameters:

(1) Radial distance of the link from the fire–ceiling impingement point
(2) Ceiling–link separation distance
(3) Link fuse temperature
(4) The response time index (RTI) of the link

For any particular run of LAVENT, the code outputs a summary of the input information and simulation results of the calculation, in tabular form, at uniform simulation time intervals requested by the user. The output results include the following:

(1) Temperature of the upper smoke layer
(2) Height of the smoke layer interface
(3) Total mass in the layer
(4) Fire energy release rate
(5) Radial distributions of the lower-ceiling surface temperature
(6) Radial distribution of heat transfer rates to the lower- and upper-ceiling surfaces
(7) The temperature for each link and the local velocity and temperature of the ceiling jet

This annex explains LAVENT using a series of exercises in which the reader reviews and modifies a default input data file that describes vent and sprinkler actuation during fire growth in an array of wood pallets located in a warehouse-type occupancy. Results of the default simulation are discussed.

LAVENT is written in Fortran 77. The executable code operates on IBM PC-compatible computers and needs a minimum of 300 kilobytes of memory.

C.2 Introduction — The Phenomena Simulated by LAVENT. Figure C.2 depicts the generic fire scenario simulated by LAVENT. This scenario involves a fire in a building space with ceiling-mounted curtain boards and near-ceiling, fusible-link–actuated ceiling vents and sprinklers. The curtained area can be considered as one of several such spaces in a single large building compartment. By specifying that the curtains be deep enough, they can be thought of as simulating the walls of a single uncurtained compartment that is well-ventilated near the floor.

The fire generates a mixture of gaseous and solid-soot combustion products. Because of high temperature, buoyancy forces drive the products upward toward the ceiling, forming a plume of upward-moving hot gases and particulates. Cool gases are laterally entrained and mixed with the plume flow, reducing its temperature as it continues its ascent to the ceiling.

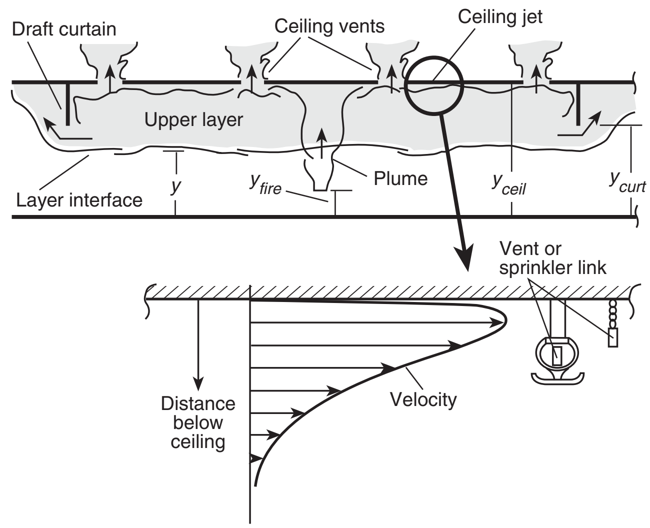

FIGURE C.2 Fire in a Building Space with Curtain Boards, Ceiling Vents, and Fusible Links.

When the hot plume flow impinges on the ceiling, it spreads under it, forming a relatively thin, high-temperature ceiling jet. Near-ceiling–deployed fusible links engulfed by the ceiling jet are depicted in Figure C.2. There is reciprocal convective cooling and heating of the ceiling jet and of the cooler lower-ceiling surface, respectively. The lower-ceiling surface is also heated due to radiative transfer from the combustion zone and cooled due to reradiation to the floor of the compartment. The compartment floor is assumed to be at ambient temperature. The upper-ceiling surface is cooled as a result of convection and radiation to a far-field, ambient temperature environment.

When the ceiling jet reaches a bounding vertical curtain board or wall surface, its flow is redistributed across the entire curtained area and begins to form a relatively quiescent smoke layer (now somewhat reduced in temperature) that submerges the continuing ceiling jet flow activity. The upper smoke layer grows in thickness. Away from bounding surfaces, the time-dependent layer temperature is assumed to be relatively uniform throughout its thickness. It should be noted that the thickness and temperature of the smoke layer affect the upper-plume characteristics, the ceiling jet characteristics, and the heat-transfer exchanges to the ceiling.

If the height of the bottom of the smoke layer drops to the bottom of the curtain board and continues downward, the smoke begins to flow below the curtain into the adjacent curtained spaces. The growth of the upper layer is retarded.

Fusible links that are designed to actuate the opening of ceiling vents and the onset of waterflow through sprinklers are deployed at specified distances below the ceiling and at specified radial distances from the plume–ceiling impingement point. These links are submerged within the relatively high-temperature, high-velocity ceiling jet flow. Because the velocity and temperature of the ceiling jet vary with location and time, the heat transfer to, and time of fusing of, any particular link design also vary.

The fusing of a ceiling vent link leads to the opening of all vents “ganged” to that link. Once a ceiling vent is open, smoke flows out of the curtained space. Again, as when smoke flows below the curtains, growth of the upper-layer thickness is retarded.

The fusing of a sprinkler link initiates the flow of water through the sprinkler. All of the described phenomena, up to the time that waterflow through a sprinkler is initiated, are simulated by LAVENT. Results cannot be used after water begins to flow through a sprinkler.

C.3 The Default Simulation. The use of LAVENT is discussed and is illustrated in the following paragraphs where exercises in reviewing and modifying the LAVENT default-simulation input file are provided. To appreciate the process more fully, a brief description of the default simulation is presented at the outset.

Note that, as explained in Section C.4, Getting Started, the user can choose to run LAVENT using either English or metric units. The default simulation uses U.S. customary units. The example in Annex D uses metric units.

The default scenario involves an 84 ft × 84 ft (25.6 m × 25.6 m) curtained compartment [7056 ft^2 (655 m^2) in area] with the ceiling located 30 ft (9.1 m) above the floor. A curtain board 15 ft (4.6 m) in depth completely surrounds and defines the compartment, which is one of several such compartments in a larger building space. The ceiling is constructed of a relatively thin sheet-steel lower surface that is well insulated from above. *[See Figure C.3(a).]*

The curtained compartment has four uniformly spaced 48 ft^2 (4.5 m^2) ceiling vents with a total area of 192 ft^2 (18 m^2), or 2.7 percent of the compartment area. Opening of the ceiling vents is actuated by quick-response fusible links with RTIs of 50 (ft·sec)$^{1/2}$ and fuse temperatures of 165°F (74°C). The links are located at the centers of the vents and 0.3 ft (0.09 m) below the ceiling surface.

Fusible-link–actuated sprinklers are deployed on a square grid with 12 ft (3.7 m) spacing between sprinklers. The links have RTIs of 400 (ft·s)$^{1/2}$ and fuse temperatures of 165°F (74°C). The sprinklers and links are mounted 1 ft (30.1 cm) below the ceiling surface.

The simulation fire involves four abutting 5 ft (1.5 m) high stacks of 5 ft × 5 ft (1.5 m × 1.5 m) wood pallets. The combined grouping of pallets makes up a combustible array 10 ft × 10 ft (3.1 m × 3.1 m) [100 ft^2 (9.3 m^2) in area] on the floor and 5 ft (1.5 m) in height. It is assumed that other combustibles in the curtained compartment are far enough away from this array that they cannot be ignited in the time interval to be simulated.

The total energy release rate of the simulation fire, $\dot{Q}$, assumed to grow from ignition, at time $t = 0$, in proportion to t^2. According to the guidance in Table F.1(a), in the growth phase of the fire, $\dot{Q}$ is taken specifically as follows:

$$\dot{Q} = 1000\left(\frac{t}{130\text{ sec}}\right)^2 \text{Btu/sec} \qquad \textbf{[C.3]}$$

The fire grows according to the preceding estimate until the combustibles are fully involved. It is then assumed that $\dot{Q}$ levels off to a relatively constant value. Following the guidance of Table 4.1 of reference [1] and Table A.8.2.6, it is estimated that, at the fully developed stage of the fire, the total energy release rate for the 5 ft (1.5 m) high stack of wood pallets will be 330 Btu/s · ft^2, or 33,000 Btu/sec for the entire 100 ft^2 array. The preceding equation leads to the result that the fully developed stage of the fire will be initiated at t_{fd} = 747 seconds.

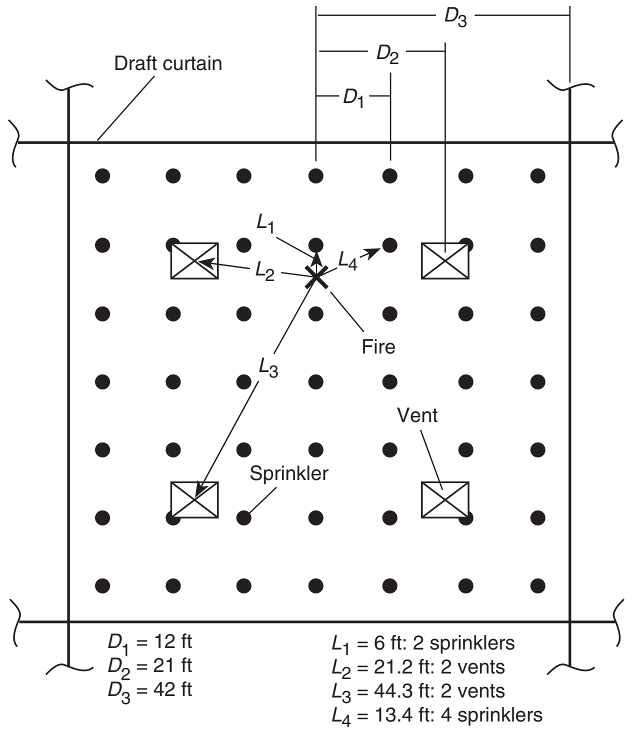

FIGURE C.3(a) Vent and Sprinkler Spacing and Fire Location for the Default Simulation.

A plot of the fire growth according to the preceding description is shown in Figure C.3(b). In the actual calculation, the fire's instantaneous energy release rate is estimated by interpolating linearly between a series of N input data points at times t_n, $n = 1$ to N, on the fire-growth curve. These points are defined by user-specified values of $\left[t_n, \dot{Q}(t_n)\right]$. For times larger than t_N, the fire's energy release rate is assumed to stay constant at $\dot{Q}(t_N)$. The calculation fire-growth curve involves six input data points (i.e., $N = 6$). These points are plotted in Figure C.3(b).

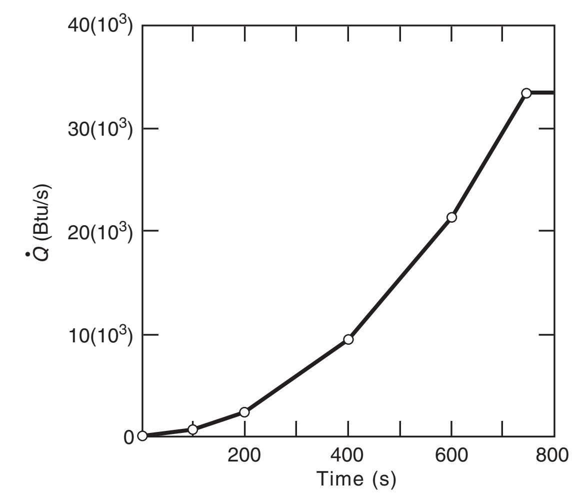

FIGURE C.3(b) Energy Release Rate vs. Time for the Fire of the Default Simulation.

The position of the fire's center is identified in Figure C.3(a). In terms of this plan view, the fire is assumed to be located at the midpoint of a 12 ft (3.7 m) line between two sprinkler links, at a distance of 21.2 ft (6.5 m) from each of the two closest equidistant vents [a total area of 96 ft^2 (8.9 m^2)] and at a distance of 44.3 ft (13.5 m) from the remaining two equidistant vents [a total area of 96 ft^2) (8.9 m^2)]. Of the sprinklers and associated links, two are closest and equidistant to the fire–plume axis at radial distances of 6 ft (1.8 m). Figure C.3(a) shows that the second and third closest groups of sprinklers and links are at radial distances of 13.4 ft (4.1 m) (four sprinklers and links) and 18 ft (5.5 m) (two sprinklers and links). In the default calculation, the opening of each of the four vents occurs, and the flow out of the vents is initiated at the simulated time of fusing of their associated links. Also simulated in the default calculation is the thermal response, including time of fusing, of the pair of sprinkler links closest to the fire.

As a final specification of the fire, it is assumed that the characteristic elevation of the fire remains at a fixed value, 2.5 ft (0.8 m) above the floor, at the initial mid-elevation of the array of combustibles. For the purpose of the default calculation, the simulation is carried out to $t = 400$ seconds, with data output every 30 seconds.

Having described the default simulation, the procedure for getting started and using LAVENT follows.

C.4 Getting Started. The executable code, LAVENT.EXE, is found on the floppy disk. Before using it, backup copies should be made. If the user has a hard drive, a separate directory should be created and the executable code should be copied into that directory. The code operates on an IBM PC or compatible computer containing a math coprocessor. It is written in Fortran 77 and needs a minimum of 300 kilobytes of memory.

To execute LAVENT, change to the proper directory or insert a floppy disk containing a copy of the executable code and enter LAVENT <ret>. In this case, <ret> refers to the ENTER or RETURN key. The first prompt provides an option for English or metric units:

1 FOR ENGLISH UNITS
2 FOR METRIC UNITS

The program has a unit conversion function and transforms files that are in one set of units to another set. The code executes in SI units; therefore, conversion is done only on input and output in order to avoid rounding errors.

For the purposes of getting started, choose Option 1, ENGLISH UNITS. Enter 1 <ret>. The following menu will be displayed on the screen:

1 READ AND RUN A DATA FILE
2 READ AND MODIFY A DATA FILE
3 MODIFY THE DEFAULT CASE TO CREATE A NEW FILE
4 RUN THE DEFAULT CASE

If Option 1 or 2 is chosen, the program will ask for the name of the data file to be used. If the chosen file resides on the hard disk, this question should be answered by typing the path of the file name, for example, C:\subdirectory\filename. If the file is on a floppy disk, type A:filename or B:filename, depending on whether the A or B drive is being used. It is recommended that all data files use a common extender such as ".dat" to facilitate identification of these files.

A first-time user should select Option 4, RUN THE DEFAULT CASE, by entering 4 <ret>. This selection will ensure that the code has been transferred intact. The default-case output is provided in Figure C.4 and is discussed in Section C.8. As a point of information, the times needed to carry out the default simulation on IBM PC-compatible 486/33 MHZ and Pentium/90 MHZ computers were 40 seconds and 8 seconds, respectively.

Now restart the code and, at this point, choose Option 3, MODIFY THE DEFAULT CASE, to review and modify the default input data. Enter 3 <ret>.

C.5 The Base Menu.

C.5.1 Modifying the Default Case — General. When Option 3, MODIFY THE DEFAULT CASE, is chosen, the following menu is displayed:

1 ROOM PROPERTIES
2 PHYSICAL PROPERTIES
3 OUTPUT PARAMETERS
4 FUSIBLE LINK PROPERTIES
5 FIRE PROPERTIES
6 SOLVER PARAMETERS
0 NO CHANGES

This menu will be referred to as the *base menu*.

Entering the appropriate option number of the base menu and then <ret> will always transfer the user to the indicated item on the menu. Entering a zero will transfer the user to the file status portion of the input section discussed in Section C.6.

The next subsections discuss data entry under Options 1 through 6 of the base menu.

Now choose Option 1, ROOM PROPERTIES, of the base menu to review and modify the default room-property input data. Enter 1 <ret>.

C.5.2 Room Properties. When Option 1, ROOM PROPERTIES, of the base menu is chosen, the following room properties menu is displayed:

1	30.00000	CEILING HEIGHT (FT)
2	84.00000	ROOM LENGTH (FT)
3	84.00000	ROOM WIDTH (FT)
4	2	NUMBER OF VENTS, ETC.
5	336.00000	CURTAIN LENGTH (FT)
6	15.00000	HEIGHT TO BOTTOM OF CURTAIN (FT)
0		TO CHANGE NOTHING

All input values are expressed in either S.I. or U.S. customary units, and the units are prompted on the input menus.

Note that the default number of vents is 2, not 4, because the symmetry of the default scenario, as indicated in Figure C.3(a), leads to "ganged" operation of each of two pairs of the four vents involved.

To change an input value in the preceding room properties menu — for example, to change the ceiling height from 30 ft to 20 ft — the user would enter 1 <ret> and 20. <ret>. The screen would show revisions using the new value of 20 ft for the ceiling height. This value or other values on this screen can be changed by repeating the process.

WARNING: *The user is warned that it is critical to end each entry number with a decimal point when a noninteger number is indicated (i.e., when the screen display shows a decimal point for that entry). The user is warned further that the code will attempt to run with any specified input file and that it will not distinguish between realistic and unrealistic input values.*

```
CEILING HEIGHT =           30.0 FT

FIGURE C.4 ***Continued***

Option 6, HEIGHT TO BOTTOM OF CURTAIN, of the room properties menu is used to define the height above the floor of the bottom of the curtain. As can be seen, in the default data, this is 15 ft. Where this height is chosen to be identical to the ceiling height, the user should always define the very special idealized simulation associated with an extensive, unconfined ceiling fire scenario (i.e., by whatever means, it is assumed that the flow of the ceiling jet is extracted from the compartment at the extremities of the ceiling). Under such a simulation, an upper layer never develops in the compartment. The lower-ceiling surface and fusible links are submerged in and respond to an unconfined ceiling jet environment, which is unaffected by layer growth. This idealized fire scenario, involving the unconfined ceiling, is used, for example, in reference [1] to simulate ceiling response and in references [2] and [3] to simulate sprinkler response.

The choice of some options on a menu, such as Option 4, NUMBER OF VENTS, ETC., of the room properties menu, leads to a subsequent display/requirement of additional associated input data. Menu options that necessitate multiple entries are indicated by the use of "ETC." In the case of Option 4, NUMBER OF VENTS, ETC., three values are involved for each vent or group of vents actuated by a fusible link. As indicated under Option 4, NUMBER OF VENTS, ETC., the default data describe a scenario with two vents or groups of vents.

Now choose Option 4, NUMBER OF VENTS, ETC., to review and modify the default input data associated with these two vents or groups of vents. Enter 4 <ret>. The following is displayed on the screen:

VENT NO. = 1 FUSIBLE LINK = 2 VENT AREA = 96.00000 FT2

VENT NO. = 2 FUSIBLE LINK = 3 VENT AREA = 96.00000 FT2

ENTER 6 TO REMOVE A VENT

ENTER VENT NO., LINK NO., AND VENT AREA (FT2) TO ADD OR MODIFY A VENT

MAXIMUM NO. OF VENTS IS 5

ENTER 0 TO RETURN TO THE MENU

This display indicates that the two simulated vents or groups of vents are numbered 1 (VENT NO. = 1) and 2 (VENT NO. = 2), that they are actuated by fusible links numbered 2 (FUSIBLE LINK = 2) and 3 (FUSIBLE LINK = 3), respectively, and that each of the two vents or groups of vents has a total area of 96 ft^2 (VENT AREA = 96.00000 FT2).

In the default fire scenario, it would be of interest to study the effect of "ganging" the operation of all four vents (total area of 192 ft^2) to fusing of the closest vent link. To do so, it would be necessary to first remove vent number 2, as identified in the preceding menu, and then to modify the area of vent number 1.

To remove vent number 2, enter 6 <ret>. The following is now displayed on the screen:

ENTER NUMBER OF VENT TO BE ELIMINATED
ENTER 0 TO RETURN TO MENU

Now enter 2 <ret>. This completes removal of vent 2, with the following revision displayed on the screen:

VENT NO. = 1 FUSIBLE LINK = 2 VENT AREA = 96.00000 FT2
ENTER 6 TO REMOVE A VENT
ENTER VENT NO., LINK NO., AND VENT AREA (FT2) TO ADD OR MODIFY A VENT
MAXIMUM NO. OF VENTS IS 5
ENTER 0 TO RETURN TO THE MENU

Now modify the characteristics of vent number 1. To do so, enter 1 <ret>, 2 <ret>, 192. <ret>. The screen will now display the following:

VENT NO. = 1 FUSIBLE LINK = 2 VENT AREA = 192.00000 FT2
ENTER 6 TO REMOVE A VENT
ENTER VENT NO., LINK NO., AND VENT AREA (FT2) TO ADD OR MODIFY A VENT
MAXIMUM NO. OF VENTS IS 5
ENTER 0 TO RETURN TO THE MENU

To add or reimplement vent number 2, actuated by link number 3 and of area 96 ft^2, enter 2 <ret>, 3 <ret>, 96. <ret>. Now return to the original default scenario by bringing the area of vent number 1 back to its original 96 ft^2 value; enter 1<ret>, 2 <ret>, and 96. <ret>.

The user can now continue to modify or add additional ceiling vents or return to the room properties menu by entering 0 <ret>. If the user tries to associate a vent with a link not yet entered in the program, the code will warn the user, give the maximum number of links available in the present data set, and request a new link value. If the user deletes a link that is assigned to a vent, the code will assign the link with the next smallest number to that vent. The best method for assigning vents to links is to first use Option 4, FUSIBLE LINK PROPERTIES, of the base menu (to be discussed in C.5.5) to assign the link parameters and then to use Option 1, ROOM PROPERTIES, followed by the option NUMBER OF VENTS, ETC. to assign vent properties.

Now return to the room properties menu by entering 0 <ret>, then to the base menu by entering 0 <ret> again.

With the base menu back on the screen, choose Option 2, PHYSICAL PROPERTIES, to review and/or modify the default room property input data. Enter 2 <ret>.

C.5.3 Physical Properties. When Option 2, PHYSICAL PROPERTIES, of the base menu is chosen, the following physical properties menu is displayed:

MATERIAL = INSULATED DECK (SOLID POLYSTYRENE)
HEAT CONDUCTIVITY = 2.400E-05 (BTU/S LB F)
HEAT CAPACITY = 2.770E-01 (BTU/LB F)
DENSITY = 6.550E+01 (LB/FT3)

1	80.00000	AMBIENT TEMPERATURE (F)
2	0.50000	MATERIAL THICKNESS (FT)
3	MATERIAL =	INSULATED DECK (SOLID POLYSTYRENE)
0		CHANGE NOTHING

The values in Options 1 and 2 are modified by entering the option number and then the new value.

Now choose Option 3 by coding 3 <ret>. The following menu is displayed:

1 CONCRETE
2 BARE METAL DECK
3 INSULATED DECK (SOLID POLYSTYRENE)
4 WOOD
5 OTHER

By choosing one of Options 1 through 4 of this menu, the user specifies the material properties of the ceiling according to the table of standard material properties in reference [4]. When the option number of one of these materials is chosen, the material name, thermal conductivity, heat capacity, and density are displayed on the screen as part of an updated physical properties menu.

Now choose Option 5, OTHER, by entering 5 <ret>. The following screen is displayed:

ENTER MATERIAL NAME
THERMAL CONDUCTIVITY (BTU/S FT F)
HEAT CAPACITY (BTU/LB F)
DENSITY (LB/FT3)

The four indicated inputs are required. After they are entered, the screen returns to an updated physical properties menu.

Now return to the default material, INSULATED DECK (SOLID POLYSTYRENE). To do so, enter any arbitrary material name with any three property values (enter MATERIAL<ret>, 1. <ret>, 1. <ret>, 1. <ret>); then choose Option 3, MATERIAL, from the menu displayed (enter 3 <ret>); and, from the final menu displayed, choose Option 3, INSULATED DECK (SOLID POLYSTYRENE) by entering 3 <ret>.

Now return to the base menu. Enter 0 <ret>. Choose Option 3, OUTPUT PARAMETERS, of the base menu to review or modify the default output-parameter data. Enter 3 <ret>.

C.5.4 Output Parameters. When Option 3, OUTPUT PARAMETERS, of the base menu is chosen, the following output-parameters menu is displayed:

1	400.000000	FINAL TIME (S)
2	30.000000	OUTPUT INTERVAL (S)
0		CHANGE NOTHING

FINAL TIME represents the ending time of the calculation. OUTPUT INTERVAL controls the time interval between successive outputs of the calculation results. All times are in seconds. For example, assume that it is desired to run a fire scenario for 500 seconds with an output of results every 10 seconds. First choose Option 1 with a value of 500 (enter 1 <ret>, 500. <ret>), then Option 2 with a value of 10 (enter 2 <ret>, 10. <ret>). The following revised output-parameters menu is displayed:

1	500.000000	FINAL TIME (S)
2	10.000000	OUTPUT INTERVAL (S)
0		CHANGE NOTHING

Return to the original default output parameters menu by entering 1 <ret>, 400. <ret>, followed by 2 <ret>, 30. <ret>.

Now return to the base menu from the output parameters menu by entering 0 <ret>.

With the base menu back on the screen, choose Option 4, FUSIBLE LINK PROPERTIES, to review or modify the default fusible link properties data. Enter 4 <ret>.

C.5.5 Fusible Link Properties. When Option 4, FUSIBLE LINK PROPERTIES, of the base menu is chosen, the following fusible link properties menu is displayed:

TO ADD OR CHANGE A LINK, ENTER LINK NO., RADIUS (FT), DISTANCE BELOW CEILING (FT), RTI (SQRT[FT S]), AND FUSE TEMPERATURE (F).
MAXIMUM NUMBER OF LINKS EQUALS 10.
ENTER 11 TO REMOVE A LINK.
ENTER 0 TO RETURN TO THE MENU.

LINK #	RADIUS (FT)	DISTANCE (FT) BELOW CEILING	RTI SQRT (FT S)	FUSE TEMP (F)
1	6.000	1.000	400.000	165.000
2	21.200	0.300	50.000	165.000
3	44.300	0.300	50.000	165.000

Each fusible link must be assigned a link number (e.g., LINK # = 1), radial position from the plume–ceiling impingement point (e.g., RADIUS = 6.00 FT), ceiling-to-link separation distance (e.g., DISTANCE BELOW CEILING = 1.00 FT), response time index (e.g., RTI = 400.00 SQRT[FT S]), and fuse temperature (e.g., FUSE TEMPERATURE = 165.00 F).

Suppose that in the default fire scenario it was desired to simulate the thermal response of the group of (four) sprinkler links second closest to the fire. According to the description in Section C.3 and in Figure C.3(a), this would be done by adding a fourth link, link number 4, at a radial distance of 13.4 ft, 1 ft below the ceiling, with an RTI of 400 $(ft/sec)^{1/2}$ and a fusion temperature of 165°F. To do this, enter 4 <ret>, 13.4 <ret>, 1. <ret>, 400. <ret>, 165.<ret>. Then the following screen is displayed:

TO ADD OR CHANGE A LINK, ENTER LINK NO., RADIUS (FT), DISTANCE BELOW CEILING (FT), RTI (SQRT[FT S]), AND FUSE TEMPERATURE (F).
MAXIMUM NUMBER OF LINKS EQUALS 10.
ENTER 11 TO REMOVE A LINK.
ENTER 0 TO RETURN TO THE MENU.

LINK #	RADIUS (FT)	DISTANCE (FT) BELOW CEILING	RTI SQRT (FT S)	FUSE TEMP (F)
1	6.000	1.000	400.000	165.000
2	13.400	1.000	400.000	165.000
3	21.200	0.300	50.000	165.000
4	44.300	0.300	50.000	165.000

Note that the new link, which was entered as link number 4, was sorted automatically into the list of the original three links and that all four links were renumbered according to radial distance from the fire. The original link-vent assignments are preserved in this operation. Hence, the user need not return to Option 4, NUMBER OF VENTS, ETC., unless it is desired to reassign link-vent combinations.

A maximum of 10 link responses can be simulated in any one simulation.

Now remove link number 2 to return to the original default array of links. To do so, enter 11 <ret>. The following screen is displayed:

ENTER THE NUMBER OF THE LINK TO BE REMOVED

Enter 2 <ret> to remove link 2.

Now return to the base menu from the fusible link properties menu by entering 0 <ret>.

With the base menu back on the screen, choose Option 5, FIRE PROPERTIES, to review or modify the default fire properties data. Enter 5 <ret>.

C.5.6 Fire Properties. When Option 5, FIRE PROPERTIES, from the base menu is chosen, the following fire properties menu is displayed:

1	2.5	FIRE HEIGHT (FT)
2	330.0	FIRE POWER/AREA (BTU/S FT2), ETC.
3		FIRE OUTPUT AS A FUNCTION OF TIME
0		CHANGE NOTHING

The value associated with Option 1 is the height of the base of the fire above the floor. Change this to 3 ft, for example, by entering 1 <ret> and 3. <ret>. Then return to the default data by entering 1 <ret> and 2.5 <ret>.

The value associated with Option 2 is the fire energy release rate per fire area. It is also possible to consider simulations where the fire area is fixed by specifying a fixed fire diameter. The fire energy release rate per fire area can be changed, or the fixed fire area type of specification can be made by choosing Option 2 by entering 2 <ret>. This leads to a display of the following menu:

1	WOOD PALLETS, STACK, 5 FT HIGH	330 (BTU/S FT2)
2	CARTONS, COMPARTMENTED, STACKED 15 FT HIGH	200 (BTU/S FT2)
3	PE BOTTLES IN COMPARTMENTED CARTONS 15 FT HIGH	540 (BTU/S FT2)
4	PS JARS IN COMPARTMENTED CARTONS 15 FT HIGH	1300 (BTU/S FT2)
5	GASOLINE	200 (BTU/S FT2)
6	INPUT YOUR OWN VALUE IN (BTU/S FT2)	
7	SPECIFY A CONSTANT DIAMETER FIRE IN FT	
0	CHANGE NOTHING	

Options 1 through 5 of the preceding menu are for variable area fires. The Option 1 to 5 constants displayed on the right are the fire energy release rate per unit fire area. They are taken from Table 4.1 of reference [1]. If one of these options is chosen, an appropriately updated fire properties menu is then displayed on the screen. Option 0 would lead to the return of the original fire properties menu.

Option 6 allows any other fire energy release rate per unit fire area of the user's choice. Option 7 allows the user to specify the diameter of a constant area fire instead of an energy release rate per unit area fire. Choice of Option 6 or 7 must be followed by entry of the appropriate value. Then an appropriately updated fire properties menu appears on the screen.

To try Option 7, SPECIFY A CONSTANT DIAMETER FIRE IN FEET, enter 7 <ret>. The following screen is displayed:

ENTER YOUR VALUE FOR FIRE DIAMETER IN FT

Assume the fire diameter is fixed at 5 ft. Enter 5. <ret>. Then the following screen is displayed:

1	2.50000	FIRE HEIGHT (FT)
2	5.00000	FIRE DIAMETER (FT), ETC.
3		FIRE OUTPUT AS A FUNCTION OF TIME
0		CHANGE NOTHING

Now return to the original default fire properties menu by entering 2 <ret>. The previous menu will be displayed. In this, choose Option 1, WOOD PALLETS, STACK, 5 ft high, by entering 1 <ret>.

Option 3, FIRE OUTPUT AS A FUNCTION OF TIME, of the fire properties menu allows the user to prescribe the fire as a function of time. The prescription involves: (1) linear interpolation between adjacent pairs of user-specified points with coordinates (time in seconds, fire energy release rate in BTU/sec); and (2) continuation of the fire to an arbitrarily large time at the fire energy release rate of the last data point.

Now choose Option 3 by entering 3 <ret>. The following screen associated with the default fire output data is displayed:

1	TIME(s) = 0.00000	POWER(BTU/S) = 0.00000E+0
2	TIME(s) = 100.0000	POWER(BTU/S) = 0.59200E+03
3	TIME(s) = 200.0000	POWER(BTU/S) = 0.23670E+04
4	TIME(s) = 400.0000	POWER(BTU/S) = 0.94680E+04
5	TIME(s) = 600.0000	POWER(BTU/S) = 0.21302E+05
6	TIME(s) = 747.0000	POWER(BTU/S) = 0.33000E+05

ENTER DATA POINT NO., TIME (S), AND POWER (BTU/S)

ENTER 11 TO REMOVE A POINT

ENTER 0 TO RETURN TO MENU

As discussed in Section C.3, with use of the six preceding data points, the default simulation will estimate the fire's energy release rate according to the plot of Figure C.3(b).

Additional data points can be added to the fire growth simulation by entering the new data point number, <ret>, the time in seconds, <ret>, the energy release rate in BTU/sec, and <ret>.

The maximum number of data points permitted is 10. The points can be entered in any order. A sorting routine will order the points by time. One point must correspond to zero time.

As an example of adding an additional data point to the preceding six, assume that a closer match to the "*t*-squared" default fire growth curve was desired between 200 seconds and 400 seconds. From Section C.3 it can be verified that the fire energy release rate will be 5325 BTU/sec at $t = 300$. To add this point to the data, thereby forcing the fire growth curve to pass exactly through the "*t*-squared" curve at 300 seconds, enter 7 <ret>, 300. <ret>, and 5325. <ret>. The following revised screen will be displayed:

1	TIME(s) = 0.0000	POWER(BTU/S) = 0.00000E+00
2	TIME(s) = 100.0000	POWER(BTU/S) =0.59200E+03
3	TIME(s) = 200.0000	POWER(BTU/S) = 0.23670E+04
4	TIME(s) = 300.0000	POWER(BTU/S) = 0.53250E+04
5	TIME(s) = 400.0000	POWER(BTU/S) =0.94680E+04
6	TIME(s) = 600.0000	POWER(BTU/S) = 0.21302E+05
7	TIME(s) = 747.0000	POWER(BTU/S) = 0.33000E+05

ENTER DATA PT. NO., TIME (S), AND POWER (BTU/S)

ENTER 11 TO REMOVE A POINT

ENTER 0 TO RETURN TO MENU

Note that the revised point, which was entered as point number 7, has been resorted into the original array of data points and that all points have been renumbered appropriately.

Now remove the point just added (which is now point number 4). First enter 11 <ret>. Then the following screen is displayed:

ENTER THE NUMBER OF THE DATA POINT TO BE REMOVED

Now enter 4 <ret>. This brings the fire growth simulation data back to the original default set of values.

Now return to the fire properties menu. Enter 0 <ret>. Then return to the base menu by entering again 0 <ret>.

With the base menu back on the screen, it is assumed that the inputing of all data required to define the desired fire simulation is complete. Now choose Option 0, NO CHANGES, to proceed to the file status menu. Enter 0 <ret>.

C.5.7 Solver Parameters. Users of the code will generally have no need to refer to this section (i.e., especially when learning to use the LAVENT code, a user should now skip to Section C.6), since they are rarely, if ever, expected to run into a situation where the code is not able to obtain a solution for a particular application or is taking an inordinate amount of time to produce the solution. However, if this does happen, there are a number of variations of the default solver parameter inputs that can resolve the problem.

Start the input part of the program to get to the base menu. Then choose Option 6, SOLVER PARAMETERS, by entering 6 <ret>. The following input options menu will be displayed:

1	0.6500E+00	GAUSS-SEIDEL RELAXATION
2	0.1000E-04	DIFF EQ SOLVER TOLERANCE
3	0.1000E-04	GAUSS-SEIDEL TOLERANCE
4	2.000000	FLUX UPDATE INTERVAL (S)
5	6	NUMBER OF CEILING GRID POINTS, MIN=2, MAX=50
6	0.1000E-07	SMALLEST MEANINGFUL VALUE
7		CHANGE NOTHING

The solvers used in this code consist of a differential equation solver DDRIVE2, used to solve the set of differential equations associated with the layer and the fusible links, and a Gauss–Seidel/tridiagonal solver using the Crank–Nicolson formalism to solve the set of partial differential equations associated with the heat conduction calculation for the ceiling. Because two different solvers are being used in the code, there is potential for the solvers to become incompatible with each other, particularly if the upper layer has nearly reached a steady-state temperature but the ceiling is still increasing its temperature. When this occurs, the differential equation solver will try to take time steps that are too large for the Gauss–Seidel solver to handle, and a growing oscillation in the ceiling temperature variable might occur. By reducing the FLUX UPDATE INTERVAL, the growing oscillation can be suppressed. The smaller the FLUX UPDATE INTERVAL, the slower the code will run.

The GAUSS–SEIDEL RELAXATION coefficient can be changed to produce a faster running code or to handle a case that will not run with a different coefficient. Typical values of this coefficient should range between 0.2 and 1.0.

The DIFF EQ SOLVER TOLERANCE and the GAUSS–SEIDEL TOLERANCE can also be changed. Decreasing or increasing these values can provide a faster running code for a given case, and by decreasing the value of the tolerances, the accuracy of the calculations can be increased. If the tolerance values are made too small, the code will either run very slowly or not run at all. Suggested tolerances would be in the range of 0.00001 to 0.000001.

Consistent with the model assumptions, accuracy in the radial ceiling temperature distribution around the plume–ceiling impingement point is dependent on the NUMBER OF CEILING GRID POINTS. Relatively greater or lesser accuracy is achieved by using relatively more or fewer grid points. This leads, in turn, to a relatively slower or faster computer run.

C.6 File Status — Running the Code. When Option 0, NO CHANGES, of the base menu is chosen, the following file status menu is displayed:

1 SAVE THE FILE AND RUN THE CODE
2 SAVE THE FILE BUT DON'T RUN THE CODE
3 DON'T SAVE THE FILE BUT RUN THE CODE
4 ABORT THE CALCULATION

If one of the save options is selected, the user will be asked to supply a file name to designate the file where the newly generated input data are to be saved. The program will automatically create the new file. File names may be as long as eight characters and should have a common extender such as .DAT (for example MYFILE.DAT). The maximum length that can be used for the total length of input or output files is 25 characters. For example, C:\SUBDIRECT\FILENAME.DAT would allow a file named FILENAME.DAT to be read from the subdirectory SUBDIRECT on the C drive. To read a file from a floppy disk in the A drive, use A:FILENAME.DAT. If Option 4 is chosen, the program will end without any file being saved.

A request for an output file name can appear on the screen. File names can be as long as eight characters and should have an extender such as ".OUT" so that the output files can easily be recognized. To output a file to a floppy disk in the A drive, name the file A:FILENAME.OUT. To output a file to a subdirectory other than the one that is resident to the program, use C:\SUBDIRECT\FILENAME.OUT for the subdirectory SUBDIRECT.

Once the output file has been designated, the program will begin to execute. The statement PROGRAM RUNNING will appear on the screen. Each time the program writes to the output file, a statement such as T = 3.0000E01 S will appear on the screen to provide the user with the present output time.

C.7 The Output Variables and the Output Options. The program generates two separate output files. An example of the first output file is appended at the end of this document. This file is named by the user and consists of a listing of the input data plus all the relevant output variables in a format where the output units are specified and the meanings of all but three of the output variables are clearly specified. These latter variables are *TSL, QB,* and *QT*, the temperature of the ceiling inside the enclosure, the net heat transfer flux to the bottom surface of the ceiling, and the net heat transfer flux to the top surface of the ceiling, respectively. The variables are output as a function of radius, with $R = 0$ being the center of the fire plume projected on the ceiling. Other abbreviations include LYR TEMP, LYR HT, LYR MASS, JET VELOCITY, and JET TEMP — the upper-layer (layer adjacent to the ceiling) temperature, height of the upper-layer interface above the floor, mass of gas in the layer, ceiling jet velocity, and ceiling jet temperature at the position of each fusible link, respectively. The VENT AREA is the total area of roof vents open at the time of output.

The second output file, GRAPH.OUT, is used by the graphics program GRAPH. GRAPH is a Fortran program that makes use of a graphics software package to produce graphical output of selected output variables [5, 6]. To use the graphics program, the file GRAPH.OUT must be in the same directory as the program GRAPH. GRAPH is a menu-driven program that provides the user with the ability to plot two sets of variables on the PC screen. An option exists that permits the user to print the plots from the screen to a printer. If using an attached EPSON-compatible printer, enter <ret> to produce a plot using the printer. To generate a PostScript file for use on a laser printer, enter <ret> and provide a file name when the file name prompt appears in the upper left hand corner of the graph. To exit to screen mode from the graphics mode, enter <ret>. The file GRAPH.OUT will be destroyed each time the code LAVENT is run. If the user wishes to save the graphics file, it must be copied using the DOS copy command into another file with a different file name.

To demonstrate the use of GRAPH, start the program by entering graph <ret>. GRAPH will read in the graphics output file GRAPH.OUT, and the following screen will be displayed:

ENTER 0 TO PLOT POINTS, ENTER 1 TO PLOT AND CONNECT POINTS

The graphics presented in Figure C.7(a) through Figure C.7(e) were done with GRAPH using option 0. Enter 0 <ret> and the following graphics menu is displayed:

ENTER THE X AND Y VARIABLES FOR THE DESIRED TWO GRAPHS

1 TIME
2 LAYER TEMPERATURE
3 LAYER HEIGHT
4 LAYER MASS
5 FIRE OUTPUT
6 CEILING VENT AREA
7 PLUME FLOW
8 LINK TEMPERATURE
9 JET VELOCITY AT LINK
10 JET TEMPERATURE AT LINK

Two plots can be studied on a single screen. For example, from the default simulation, assume that displays of the plots of Figure C.7(a) and Figure C.7(b), LAYER HEIGHT vs. TIME and LAYER TEMPERATURE vs. TIME, respectively, are desired. Then enter 1 <ret>, 3 <ret>, 1 <ret>, and 2 <ret>. The program will respond with the following prompt:

ENTER THE TITLES FOR THE TWO GRAPHS, 16 CHARACTERS MAX.

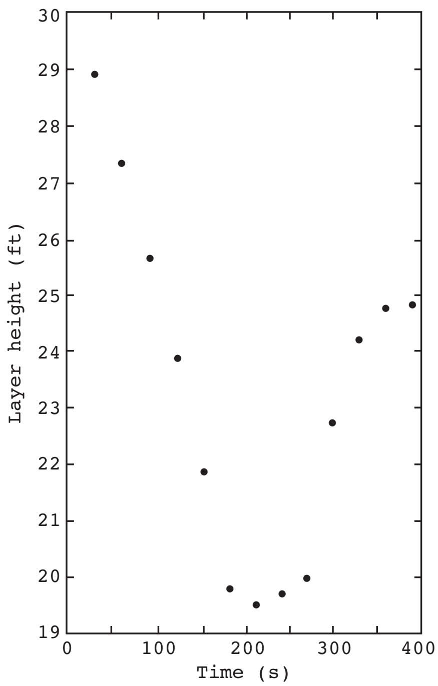

FIGURE C.7(a) Plot of the Height of the Smoke Layer Interface vs. Time for the Default Simulation.

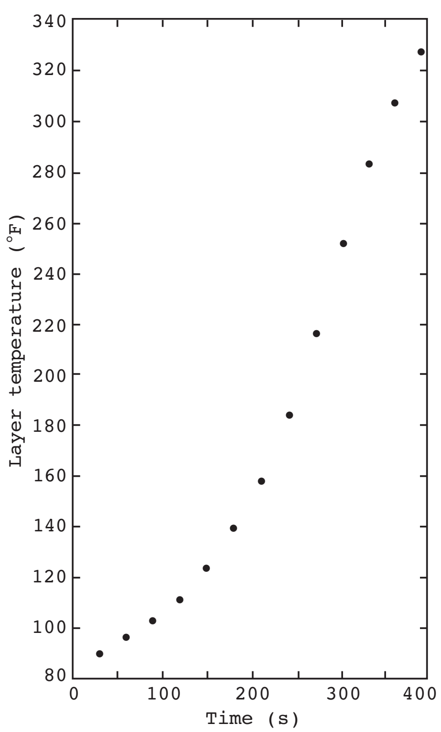

FIGURE C.7(b) Plot of the Temperature of the Smoke Layer vs. Time for the Default Simulation.

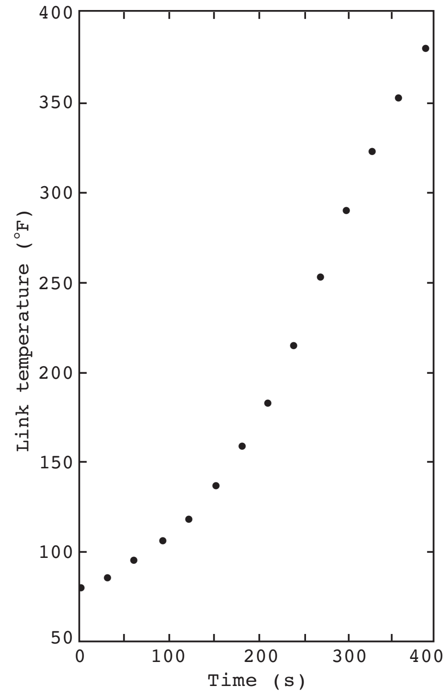

FIGURE C.7(c) Plot of the Closest (*R* = 21.2 ft) Vent-Link Temperature vs. Time for the Default Simulation.

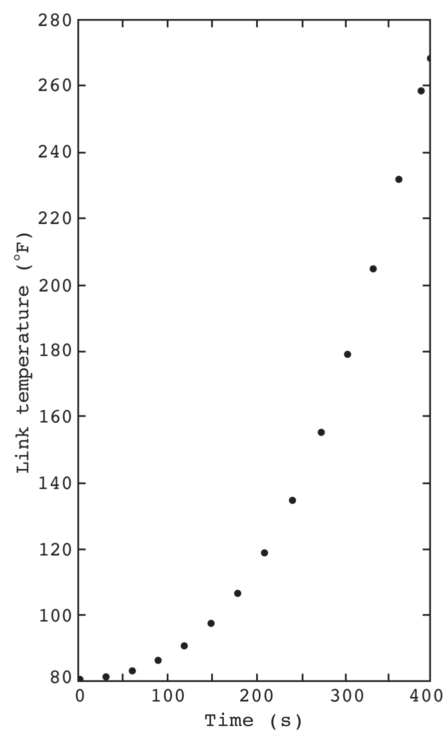

FIGURE C.7(d) Plot of the Far (*R* = 44.3 ft) Pair of Vent-Link Temperatures vs. Time for the Default Simulation.

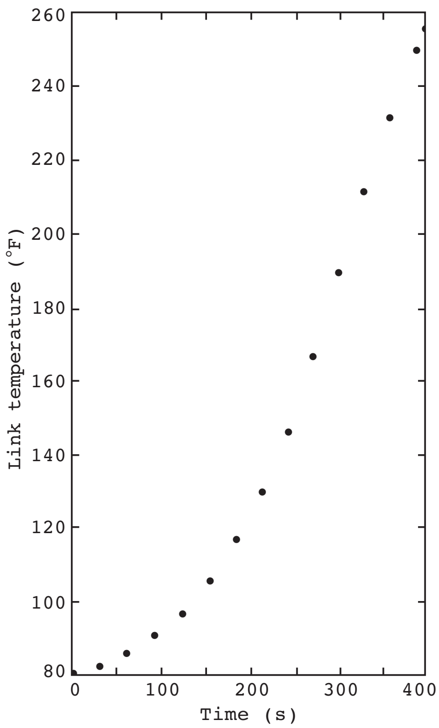

FIGURE C.7(e) Plot of the Closest (*R* = 6 ft) Sprinkler-Link Temperatures vs. Time for the Default Simulation.

The user might choose titles that would identify particular cases such as LY HT RUN 100 <ret> and LY TEMP RUN 100 <ret>. If a title longer than 16 characters is chosen, it will be truncated to 16 characters. After the titles have been entered, the program will respond with the following prompt:

ENTER 1 FOR DEFAULT SCALING, 2 FOR USER SCALING.

If the user chooses option 1, the desired plots will appear on the screen with an internal scaling for the *x*- and *y*-axis of each graph. If the user chooses option 2, the program will respond with the following prompt:

ENTER THE MINIMUM AND MAXIMUM VALUES FOR THE X AND Y AXIS OF EACH GRAPH.

ENTER 0 FOR THE MINIMUM AND MAXIMUM VALUES OF EACH AXIS WHERE DEFAULT SCALING IS DESIRED. FOR EXAMPLE, VALUES SHOULD BE ENTERED AS 0.,100.,0.,200.,10.,50.,20.,100.<ret> FOR X1(0-100), Y1(0-200), X2(10-50), Y2(20-100).

Use of this option allows a number of different cases to be compared using similar values for the *x*- and *y*-axis of each graph. All eight numbers must be entered and separated with commas before entering <ret>. Once the entry is made, the plots will appear on the screen. Note that this option permits a mixture of default scaling and user-specified scaling.

Once a pair of plots are displayed on the screen, the user would have the choice of entering <ret> to obtain a hard-copy plot of the graphs or of entering <ret> to exit the graphics mode.

To plot a second pair of graphs, the user would exit the graphics mode by entering <ret> and then repeat the preceding process by entering graph <ret>, and so forth.

If the user selects plots that involve variables defined by Option 8, 9, or 10, then, following the entry 8 <ret>, 9 <ret>, or 10 <ret>, the following prompt for identifying the desired link number (in the default simulation with three simulated links) will be displayed immediately:

ENTER LINK NUMBER, MAXIMUM NUMBER = 3

The user would then enter the desired link number followed by <ret> and continue entering the remaining input data that define the desired plots.

As an example of generating link-related plots, consider displaying the pair of plots LINK TEMPERATURE vs. TIME and JET VELOCITY AT LINK vs. TIME for link number 3 in the default simulation. First enter 1 <ret> (for TIME on the *x*-axis) and 8 <ret> (for LINK TEMPERATURE on the *y*-axis). At this point, "ENTER LINK NUMBER . . ." would be displayed on the screen. Continue by entering 3 <ret> (for link number 3). This would complete the data entry for the first of the two plots. For the second plot, enter 1 <ret> (for TIME on the *x*-axis) and 9 <ret> (for LINK TEMPERATURE on the *y*-axis). At this point, "ENTER LINK NUMBER . . ." would be displayed a second time. Then conclude data input for the pair of plots by entering 3 <ret> (for link number 3). At this point the desired pair of plots would be displayed on the screen.

C.8 An Example Simulation — The Default Case. This section presents and reviews briefly the simulation of the default case.

The tabular output of the default simulation is presented in Figure C.4. Plots of the layer-interface height and of the layer temperature as functions of time are plotted in Figure C.7(a) and Figure C.7(b), respectively. Plots of the thermal response of the two pairs of vent links and the pair of sprinkler links closest to the fire are presented in Figure C.7(c) through Figure C.7(e), respectively.

From Figure C.4 and Figure C.7(c) through Figure C.7(e), it is seen that the sequence of link fusing (at 165°F) is predicted to be the near pair of vents at 187 seconds, the far pair of vents at 267 seconds, and the pair of closest sprinklers at 283 seconds. Although the sprinkler links are closer to the fire than any of the vent links, and although all links have the same fuse temperatures, the simulation predicts that the sprinkler links fuse after all of the vent links. There are two reasons for this. First, the RTIs of the sprinkler links are larger than those of the vent links and, therefore, slower to respond thermally. Second, the two sprinkler links simulated are far enough from the ceiling as to be below the peak temperature of the ceiling jet, which is relatively thin at the 6 ft radial position (see the lower sketch of Figure C.2).

The effect on layer growth of fusing of the two pairs of vent links and opening of their corresponding vents at 187 seconds and 267 seconds can be noted in Figure C.7(a). Note that the opening of the first pair of vents effectively stops the rate-of-increase of layer thickness and the opening of the second pair of vents leads to a relatively rapid rate-of-decrease in the layer thickness. All of this is of course occurring at times when the energy release rate of the fire is growing rapidly.

As can be seen in Figure C.7(a), up until the 400 seconds of simulation time, the smoke is still contained in the original curtained compartment and has not "spilled over" to adjacent spaces. From this figure it appears that with no venting, the layer would have dropped below the bottom of the curtain boards prior to fusing of the first sprinkler links. This could be confirmed with a second simulation run of LAVENT, where all vent action was removed from the default data.

Annex D Sample Problem Using Engineering Equations (Hand Calculations) and LAVENT

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

D.1 Abstract. The following example problem illustrates the use of the information, engineering equations, hand calculations, and computer model described in this document. The impact of a fire on a nonsprinklered retail storage building and its occupants is assessed. The effects of an anticipated fire on the subject building are predicted, and the impact of smoke and heat vents is illustrated.

Design goals and objectives were developed, and a high-challenge fire, likely to occur in the subject building, was identified. The fire impact was assessed using three different methods:

(1) Hand calculations assuming a quasi-steady fire
(2) Hand calculations assuming a continuous-growth (*t*-squared) fire
(3) The computer model LAVENT

Hand calculations are useful for generating quick estimates of the impact of vents on fire effects. However, hand calculations are not able to assess time-varying events. A number of simplifying assumptions have been used to facilitate problem solving via algebraic equations. Hand-calculated results are considered valid, but they produce slightly different estimates of fire effects such as upper-layer temperature. A computer model such as LAVENT generally provides a more complete analysis of the fire-produced effects and, in some instances, is preferable over hand calculations.

D.2 Introduction. The following example problem illustrates the use of engineering equations and a computer model to assess the impact of a fire in a nonsprinklered retail storage building. The problem illustrates the impact of vents and predicts the effect of the anticipated fire on the building.

D.2.1 Goal. Develop a vent design for the subject building that will maintain a tenable environment for a period of time at least equal to the time required to evacuate the building and equal to the time required to maintain the hot upper layer a minimum of 3 m above floor level until the local fire department enters the building.

D.2.2 Objective. Determine the vent area required to maintain the smoke layer at least 3 m above floor level for 300 seconds following detection of the fire by an automatic detection system. Also, limit the heat flux at floor level to a maximum of 2.5 kW/m^2, the threshold irradiance that causes severe pain to exposed skin [1], during the time required for evacuation of the building occupants.

D.2.3 Building Details. The building is 73 m wide, 73 m long, and 9.1 m high. It is not subdivided, nor is it provided with a sprinkler system. The roof is an insulated deck (solid polystyrene). A complete fire alarm system is to be installed using heat detectors spaced 15.2 m on center and 6.1 m from walls. Detectors will have an activation temperature of 74°C and an RTI of 55 $(m{\cdot}s)^{1/2}$ and are to be located 0.3 m below the roof. Sixteen vents are proposed, spaced 18.3 m on center. Vents will be located 9.05 m from walls. The vents will be activated by fusible links with an activation temperature of 74°C and an RTI of 28 $(m{\cdot}s)^{1/2}$ and are to be located 0.3 m below the roof. Inlet air openings will be equal to 1.5 the total vent area. *(See Figure D.2.3.)*

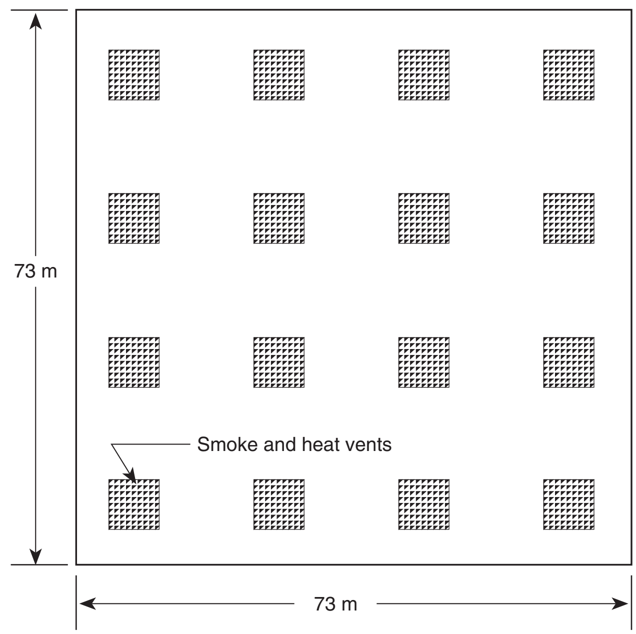

FIGURE D.2.3 Vent Plan View.

D.2.4 Occupancy Details. The building is to be occupied for retail storage. This analysis deals with a fire in rack storage of sofas in the center of the building. The sofas are to be stored in two racks, each 9.75 m long and 1.2 m wide and separated from each other by 2.4 m. Each rack will have four tiers of storage, four sofas per tier, and a total storage height of 7.6 m. Distance to combustibles surrounding the racks will be sufficient to prevent fire spread to those combustibles during the time period covered by this analysis. The sofas are identified as specimen F32 contained within Table E.5.3(d). Data for the same sofas are contained within a database of Hazard I [2], where the sofas are identified as specimen UPS001. Each sofa will contain 51.5 kg of combustible mass and be wrapped in polyethylene.

D.2.5 Ignition. An ignition is assumed to occur in a sofa on the first tier of one of the racks. Ignition of a sofa on the first tier is a probable worst-case scenario and, as a practical matter, is a location where ignition could be expected. Also, placing the fire near floor level results in near-maximum smoke production (entrainment).

D.3 Fire Growth. First, an estimate of the anticipated fire growth must be developed. A t-squared fire will be assumed *(see* 8.3.1 *and* A.8.3.1*)*. In a t-squared fire,

$$Q = \alpha_g t^2 \quad \textbf{[D.3a]}$$

where:
Q = total heat release rate (kW)
α_g = fire growth coefficient
t = time (seconds)

The data base within Hazard I [2] contains data from furniture calorimeter tests of sofas. A sofa (UPS001) was tested and demonstrated a growth time (t_g) to 1 MW of approximately 200 seconds. The fire in the sofa in this example is assumed to have a growth time of 150 seconds to 1 MW as a reasonable, conservative approximation of the anticipated fire in the sofas stored in the example building. If a more precise estimate of the burning characteristics of an individual sofa is necessary, the exact sofa to be stored in the building could be tested in a calorimeter. A fire growth time of 150 seconds results in an α_g for the individual sofa of 0.044 kW/s^2 *(see Equation 8.3.2)*. That is,

$$\alpha_g = \frac{1000}{t_g^2} = \frac{1000}{150^2} = 0.044 \text{ kW/s}^2 \quad \textbf{[D.3b]}$$

Accordingly, fire growth in the first sofa ignited can be approximated by a fast (α_g = 0.044 kW/sec^2) t-squared fire. Further, according to 8.3.1, α_g is directly proportional to the storage height. Therefore, the fire growth constant (α_g) for sofas stacked four high is 4 times 0.044 kW/s^2, or α_g equals 0.18 kW/s^2, and initial fire growth is approximated as

$$Q = \alpha_g t^2 \quad \textbf{[D.3c]}$$

where α_g = 0.18 kW/s^2.

Fire growth in the first rack of sofas results in radiant heat transfer to a second rack of sofas separated from the first rack by 2.4 m. It must be determined when the second rack of sofas ignite. The fire size, when ignition of the second rack of sofas occurs, is determined using Equation 8.2.3 with its terms rearranged:

$$Q = \frac{W}{0.042^2} \quad \textbf{[D.3d]}$$

where:
Q = fire output (kW)
W = aisle width (m)

Next, the time of ignition of the second rack is computed:

$$t = \left(\frac{Q}{\alpha_g}\right)^{1/2} = \left(\frac{3250}{0.18}\right)^{1/2} = 134 \text{ s} \quad \textbf{[D.3e]}$$

where $Q = \alpha_g t^2$.

When the second rack of sofas is ignited at 134 seconds, the fire growth coefficient, α_g, for the two racks burning together is assumed to double the value for the first rack burning alone (α_g = 0.36 kW/s^2). At that time, the fire appears to have originated at effective ignition time, t_{0g}. For t >134 seconds,

$$Q = 0.36\left(t - t_{0g}\right)^2 \text{ kW} \quad \textbf{[D.3f]}$$

Determine t_{0g} as follows:

$$3250 = 0.36\left(134 - t_{0g}\right)^2 \quad \textbf{[D.3g]}$$

where t_{0g} = 39 seconds. Then, for t > 134 seconds,

$$Q = 0.36\left(t - 39\right)^2 \quad \textbf{[D.3h]}$$

The maximum fire size is now estimated. Sofa UPS001 from the Hazard I database [2] [specimen F32 in Table E.5.3(d)] has a peak burning rate of 3120 kW. Maximum fire size, Q_{max}, is based on the assumption that all 32 sofas are burning at their individual peak rates, 3120 kW:

$$Q_{max} = 32(3120) \cong 100 \text{ MW} \quad \textbf{[D.3i]}$$

The time, t_{max}, to reach 100 MW must be determined using the following:

$$Q_{max} = 0.36\left(t - 39\right)^2 \quad \textbf{[D.3j]}$$

When Q = 100,000 kW,

$$100{,}000 = 0.36\left(t_{max} - 39\right)^2 \quad \textbf{[D.3k]}$$

$$t_{max} = \frac{(100{,}000)^{1/2}}{0.36} + 39 = 566 \text{ s} \quad \textbf{[D.3l]}$$

An estimate of fire duration, t_{end}, is now made using data from the Hazard I [2] database for sofa UPS001, where individual sofa combustible mass = 51.5 kg, sofa effective heat of combustion = 18,900 kJ/kg, and maximum fire size = 100,000 kW.

The mass consumed from t = 0 to t = 134 seconds is determined from the total heat release as follows:

$$\int_0^{134} Q\,dt = \frac{0.18}{3} t^3 \Big|_0^{134} = \frac{0.18}{3}(134)^3 = 144{,}366 \text{ kJ} \quad \textbf{[D.3m]}$$

Since $Q = \dot{m}h_c$ (see Equation E.3a), mass loss, Δm, for t = 134 seconds, is determined as follows:

$$\Delta m = \frac{144{,}366 \text{ kJ}}{18{,}900 \text{ kJ/kg}} = 7.6 \text{ kg} \quad \text{or} \cong 8 \text{ kg} \quad \textbf{[D.3n]}$$

The mass consumed from t = 134 seconds to t_{max}, the time the maximum fire size is reached, is similarly determined from the total heat release rate after 134 seconds, as follows:

[D.3o]

$$\int_{134}^{t_{max}} Q\,dt = \int_{134}^{566} 0.36\left(t - 39\right)^2 dt = \int_{134-39}^{566-39} 0.36\beta^2 d\beta = \frac{0.36}{3}(t)^3 \Big|_{95}^{527}$$

Total heat release from t = 134 to t = 566 is then = 0.12[$(527)^3$ - $(95)^3$] = 17,460,697 kJ, and the mass lost, Δm, is Δm = 17,460,697 kJ/18,900 kJ/kg = 923.8 ≅ 924 kg.

Approximately (924 + 8) kg = 932 kg is consumed during the 566 second time interval required to reach Q_{max}. The total combustible mass is 51.5 kg × 32 = 1648 kg. Therefore, around (1648 - 932) kg = 716 kg is available to burn at Q = Q_{max} = 100 MW, after t = 566 seconds, from which the fire duration can be calculated as follows:

[D.3p]

$$Q_{max}\left(t_{end} - 566\right) = 100{,}000\left(t_{end} - 566\right) = 716(18{,}900)$$

$$t_{end} = 566 + \frac{716(18{,}900)}{100{,}000} = 701.3 \text{ seconds} \cong 700 \text{ s} \quad \textbf{[D.3q]}$$

The combustible mass of the sofas alone is able to support the anticipated fire for approximately 700 seconds. In reality, the fire in the sofas would reach a maximum of 100 MW at 550–600 seconds and burn briefly at the 100 MW peak until the combustible mass available began to be consumed, at which time the fire's rate of heat release would begin to decline. Using a t_{end} of 700 seconds is conservative.

In summary, the analysis to this point leads to the following estimate for the anticipated fire:

$$Q = 0.18t^2 \quad \text{for } 0 < t \le 134 \text{ s}$$
$$Q = 0.36(t-39)^2 \quad \text{for } 134 < t \le 566 \text{ s} \qquad \textbf{[D.3r]}$$
$$Q = 100{,}000 \text{ kW} \quad \text{for } t > 566 \text{ s}$$

(See Figure D.3.)

D.4 Fire Detection. The time of fire detection is now calculated given the fire and building as described. The time of detection will be estimated based on the actual composite fire already described. Detection time can be calculated using Equation 9.2.5.4.3. DETACT-QS *(see* A.9.2.5.4.4.2*)* is a readily available computational tool that performs this calculation.

A complete fire alarm system is to be installed using heat detectors that are spaced 15.2 m on center (6.1 m from walls), have an activation temperature of 74°C, and have an RTI of 55 $(\text{m·s})^{1/2}$. Assuming the anticipated fire is as described, the maximum distance from a detector to the fire axis is the diagonal $[2(15.2/2)^2]^{1/2} = 10.7$ m, the ambient temperature is 21°C, and the fire is 0.5 m above floor level, DETACT-QS predicts the activation of a heat detector at 230 seconds. In the event quicker detection is judged to be necessary, smoke detector activation can be predicted by DETACT-QS using the guidance provided in A.9.2.5.4.4.1. Detection time for smoke detectors is based on the gas temperature rise at the detector site. Smoke detector activation can be approximated using DETACT-QS, assuming the smoke detector will respond like a heat detector, which has a small RTI [e.g., $1(\text{m·s})^{1/2}$] and a certain activation temperature above ambient *(see* A.9.2.5.4.4.1*)*. Tests involving burning of the sofa upholstery with the actual detector to be installed have determined that 10°C above ambient is a representative activation condition. Assuming smoke detectors are spaced 9.1 m on center (located a maximum of 6.5 m from the axis of the fire), smoke detector activation is predicted by DETACT-QS at 48 seconds.

Using DETACT-QS, vent operation is predicted using fusible links having an activation temperature of 74°C and an RTI of 28 $(\text{m·s})^{1/2}$. Assuming the anticipated fire is located in the center of the building, the ambient temperature is 21°C, and assuming the fire is 0.5 m above floor level, activation of the first vents (equidistant from the fire) separated $[2(18.3/2)^2]^{1/2} = 12.9$ m from the fire is predicted by DETACT-QS at 228 seconds. The next set of vents (equidistant from the fire at 28.9 m) are predicted to open at 317 seconds. Similarly, the third set of four vents, 38.8 m from the fire axis, open at 356 seconds. All 16 vents are open at 356 seconds. Alternatively, if fusible links having the same RTI as the heat detectors [55 $(\text{m·s})^{1/2}$] are used, all vents are predicted to be open at 384 seconds.

D.5 Vent Design. Of main concern in this example is the temperature of the smoke layer, which governs the heat flux radiated to the floor. Assuming an emissivity of 1 and a configuration factor of 1, the radiant heat flux at the floor is calculated as follows:

$$Flux_{fl} = k\varepsilon\Phi\pi T^4 \qquad \textbf{[D.5]}$$

where:

$Flux_{fl}$ = $(5.67 \times 10^{-11})T^4 \text{kW/m}^2$
k = Stefan–Boltzmann constant = 5.67×10^{-11} $\text{kW/m}^2\,\text{K}^4$
ε = emissivity = 1
Φ = configuration factor = 1
T = temperature of the layer (K)

For a flux limit of 2.5 kW/m^2, as stated in the objective, the temperature of the smoke layer is calculated as 458 K, or 164 K above the ambient temperature of 294 K.

D.6 Steady Fire — Smoke Layer Temperature. First, conditions following attainment of the maximum heat release rate of 100 MW can be examined (i.e., at times greater than 566 seconds) assuming a smoke layer at the lowest acceptable height, 3 m above the floor. (The heat detector installation contemplated was calculated to provide alarm at 230 seconds; 300 seconds following detection places the time of interest at 530 seconds, close to the attainment of the maximum heat release rate.)

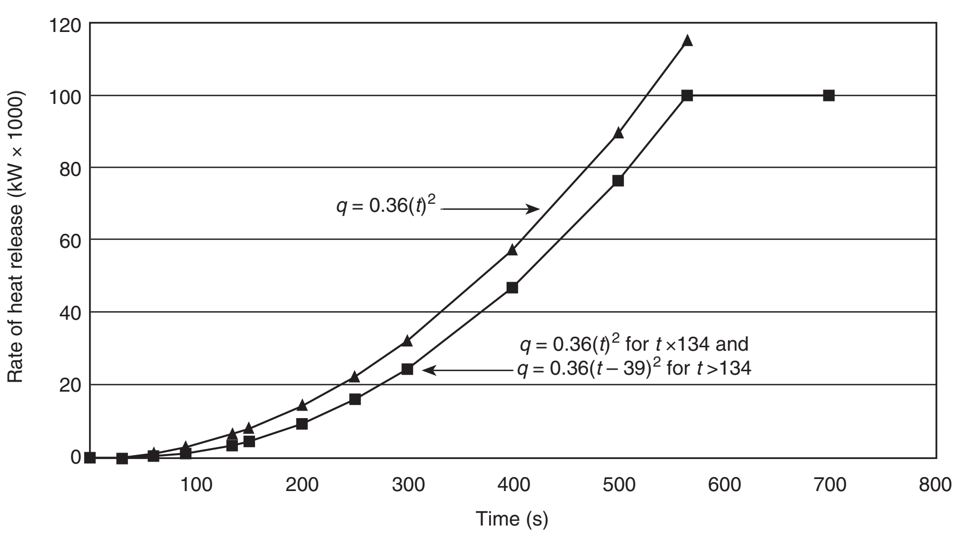

FIGURE D.3 Fire Output.

The effective diameter of the fire is required for the calculations. This diameter can be determined with the aid of Equation 8.3.7, setting Q = 100,000 kW and selecting an appropriate value for the heat release rate per unit floor area, Q''. The two racks facing each other across the 2.4 m wide aisle are 9.75 m long and 1.2 m wide *(see Figure D.6)*. The heat release rate per unit area is taken as the fully involved heat release rate, 100,000 kW, divided by the combined area of the two racks plus the aisle, or (9.75) (1.2) (2.2) + (9.75) (2.4) = 46.8 m^2. Accordingly, the heat release rate per unit area is

$$Q'' = \frac{100{,}000}{46.8} = 2136 \text{ kW/m}^2 \quad \textbf{[D.6a]}$$

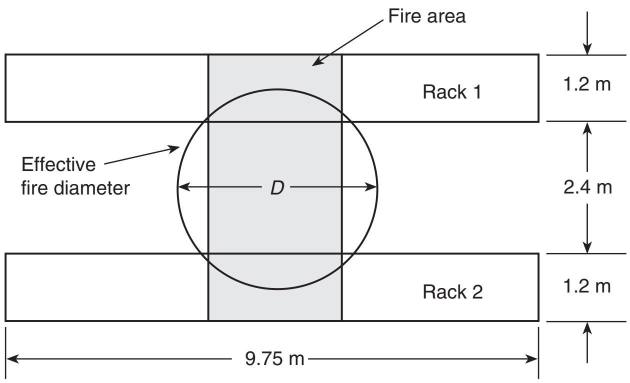

FIGURE D.6 Effective Fire Diameter.

This value can be assumed to be representative of most of the fire history, except for the initial stage. The effective diameter of the fire at 100,000 kW is then, using Equation 8.3.7,

$$D = \left[\frac{4(100{,}000)}{\pi(2136)}\right]^{1/2} = 7.72 \text{ m} \quad \textbf{[D.6b]}$$

Equation 9.2.4.3 is used to estimate the smoke layer temperature rise. The mass flow rate in the plume as it enters the smoke layer, $\dot{m}_p$, is calculated from Equation 9.2.3.6 or 9.2.3.7, depending on whether the flame height is smaller or larger than the height of the smoke layer above the base of the fire, 3-0.5 = 2.5 m. The flame height is calculated from Equation 9.2.3, as follows:

$$L = \left[-1.02(7.72)\right] + \left[0.235(100{,}000)^{2/5}\right] = 15.6 \text{ m} \quad \textbf{[D.6c]}$$

which is greater than the height of the smoke layer. (It is even greater than the ceiling height so that the flames will impinge on the ceiling and flow radially outward.) Therefore, the mass flow rate in the plume as it enters the smoke layer is calculated from Equation 9.2.3.7, as follows (assuming $Q_c = 0.7Q$):

$$\dot{m}_p = 0.0056(0.7 \times 100{,}000)\frac{2.5}{15.6} = 62.8 \text{ kg/s} \quad \textbf{[D.6d]}$$

Now the temperature rise in the smoke layer can be estimated using Equation 9.2.4.3, with C_p = 1.00 kJ/kg·K and the value of K = 0.5 recommended in 9.2.4.4.

$$\Delta T = \frac{0.5(70{,}000)}{1.00(62.8)} = 557 \text{ K} \quad \textbf{[D.6e]}$$

This value is considerably above 164 K; therefore, the floor radiant heat flux can be expected to be much higher than the limit 2.5 kW/m^2. Using the equation for radiant heat flux to the floor presented previously, the value 29.7 kW/m^2 is calculated for a smoke layer temperature of 557 + 294 = 851 K.

Not only is the smoke layer temperature, 557 + 21 = 578°C, so high that it produces unacceptable levels of radiant flux at the floor, but it is also close to the level, 600°C, where fire can flash over all the combustibles under the smoke layer. Furthermore, it exceeds the value, 540°C, where unprotected steel begins losing strength. Directly over the fire the temperatures might locally reach 1135°C (from Equation 9.2.4.3, with K=1), far in excess of the threshold for steel damage.

D.7 Sizing of Vents. This building arrangement will not meet design objectives. However, it might be instructive to investigate the venting requirements in order to illustrate general procedures that might be used to develop alternative designs.

All 16 vents are predicted to be open prior to 566 seconds — the time of interest.

The aerodynamic vent area, A_{va}, is determined with the aid of Equation 9.2.4.1:

$$\dot{m}_v = \left(2\rho_o^2 g\right)^{1/2}\left(\frac{T_o \Delta T}{T^2}\right)^{1/2} A_{va} d^{1/2} \quad \textbf{[D.7a]}$$

At equilibrium, the mass flow through the vents is equal to the smoke production rate, $\dot{m}_p$. Substituting $\dot{m}_p = 62.6$ kg/s for $\dot{m}_v$ in Equation 9.2.4.1, together with

ρ_o = 1.2 kg/m^3
g = 9.81 m/s^2
T_o = 294 K
ΔT = 559 K
T = 294 + 559 = 853 K
d = 9.1 – 3 = 6.1 m

the equation can be solved for the aerodynamic vent area. The result is

$$A_{va} = 10.04 \text{ m}^2 \quad \textbf{[D.7b]}$$

The vents are assumed to have a discharge coefficient of 0.61; therefore, the corresponding actual vent area is *(see* A.9.2.4.2*)*

$$A_v = \frac{10.04}{0.61} = 16.46 \text{ m}^2 \left(\text{geometric vent area}\right) \cong 16.5 \text{ m}^2 \quad \textbf{[D.7c]}$$

The building design contemplates that inlet air openings will be 1.5 times the vent area. Equation F.2 is used to calculate a correction, M, for the limited inlet air openings.

$$M = \left[1 + \left(\frac{A_v}{A_i^2}\right)\left(\frac{T_o}{T}\right)\right]^{1/2} \quad \textbf{[D.7d]}$$

$$M = \left[1 + \left(\frac{1}{1.5^2}\right)\left(\frac{294}{853}\right)\right]^{1/2} = 1.07 \quad \textbf{[D.7e]}$$

The corrected actual vent area is

$$(1.07)(16.5) = 17.66 \text{ m}^2 \quad \textbf{[D.7f]}$$

Distributed among the 16 vent locations, the actual area per vent is

$$\frac{17.66}{16} = 1.10 \text{ m}^2 \qquad \textbf{[D.7g]}$$

The nearest commercial vent size equal to or larger than this unit vent area would be selected.

The following equation is used to check for $Q_{feasible}$:

$$Q_{feasible} = 23{,}200(H-d)^{5/2}$$
$$Q_{feasible} = 229{,}265 \text{ kW} \cong 230 \text{ MW} \qquad \textbf{[D.7h]}$$

where:
$Q_{feasible}$ = feasible fire heat release rate (kW)
H = 9.1 − 0.5 = 8.6 m
d = 6.1 m

This value is higher than the projected heat release rate, 100 MW, and by itself is not of direct concern.

D.8 Increased Height of Smoke Interface. Inspection of Equation 9.2.3.7 indicates that the larger the height of the smoke interface above the base of the fire, the larger the value of mass entrained in the plume, $\dot{m}_p$, and Equation 9.2.4.3 indicates that the temperature rise in the smoke layer will be reduced. The calculations just completed for a smoke layer height of 3 m above the floor can be repeated for other smoke layer heights in search of acceptable alternative designs. The two additional smoke layer heights of 6 m and 7.3 m have been investigated, the latter near the maximum associated with the minimum recommended curtain depth for the 9.1 m high building *(see Section* 7.3*)*. The final results of these additional calculations indicate values of temperature rise in the smoke layer of 253 K for the 6 m high level and 205 K for the 7.3 m high level. Although these values for smoke layer temperature rise are still a little high compared to the target of 164 K, they represent a major improvement. Furthermore, the temperatures are low enough so as not to represent a flashover hazard or endanger structural steel.

The calculations for the three smoke layer heights at the maximum heat release rate are summarized in Table D.8, entered as cases 1–3. In the table, H_c represents the height of the ceiling above the floor, $H_c - d$ is the height of the smoke interface above the floor, and $H - d$ is the height of the smoke interface above the base of the fire. In cases 1–3, the radiant heat flux at floor level, $flux_{fl}$, is seen to decrease to 5.1 kW/m^2 and 3.5 kW/m^2 as the smoke interface is raised but still remains above 2.5 kW/m^2. The total required vent area (corrected A_v) increases sharply as the smoke layer interface is raised. For the largest interface height, the total vent area of 89.2 m^2 corresponds to an area per vent of 89.2/16 = 5.57 m^2, which is still smaller than the maximum vent area discussed in 5.4.1 [(i.e., $2d^2 = 2(1.8)^2 = 6.48$ m^2].

D.9 Growing Fire. Cases 4–6 in Table D.8 correspond to the growing fire with detection at 230 seconds using heat detectors. The state of the fire is represented at a time 300 seconds following detection with heat detectors (i.e., at 230 + 300 = 530 seconds). It is assumed that all 16 vents are operated together at the alarm of the first heat detector; alternatively, the vents are actuated individually with fusible links of the same RTI and activation temperature as the heat detectors, for which it might be confirmed with DETACT-QS that all vents open prior to 530 seconds. The calculations are parallel to cases 1–3, except that the fire is slightly smaller, as determined from the following:

$$Q = 0.36(t-39)^2 = 0.36(530-39)^2 = 86{,}800 \text{ kW} \qquad \textbf{[D.9a]}$$

In cases 4–6, the smoke layer temperatures (ΔT) and radiant fluxes to the floor are only slightly reduced from the corresponding steady fire situations, cases 1–3. Also, there is little change in the required vent areas.

Cases 7–9 in Table D.8 correspond to the growing fire, with detection at 48 seconds using smoke detectors. Again, the state of the fire is represented at a time 300 seconds from detection (i.e., at 348 seconds). It is assumed that the 16 vents are operated together at the alarm of the first smoke detector. The calculations are executed at a state of fire development as follows:

$$Q = 0.36(t-39)^2 = 0.36(348-39)^2 = 34{,}400 \text{ kW} \qquad \textbf{[D.9b]}$$

It is seen that case 9 meets the design objective of heat fluxes to the floor that are calculated as being lower than 2.5 kW/m^2, and case 8 nearly does so. The required vent areas are 28.3 m^2 and 47.8 m^2 for cases 8 and 9, respectively, corresponding to unit vent areas (16 vents) of 1.8 m^2 and 3.0 m^2, both of which are well below their respective maxima, $2d^2$, based on 5.4.1.

It will be noted that the case 8 solution using "hand calculations" provides an approximation close to the LAVENT predictions, which are summarized next.

D.10 LAVENT Analysis. The case 8 vent design in Table D.8 will now be analyzed using the computer program LAVENT [3]. LAVENT is able to assess the time-varying events associ-

Table D.8 Results of Calculations for Vent Design

ated with the predicted fire. The fire has been previously determined as follows:

$$Q = 0.18t^2 \text{ for } 0 < t \leq 134 \text{ s}$$
$$Q = 0.36(t-39)^2 \text{ for } 134 < t \leq 566 \text{ s} \quad \textbf{[D.10]}$$
$$Q = 100{,}000 \text{ kW for } t > 566 \text{ s}$$

The values for this fire will be used as input for LAVENT. The fire is assumed to start in the center of the building.

A complete smoke detection system is to be installed with detectors spaced 9.1 m on center. Detectors are located a maximum of 6.5 m from the fire axis (i.e., one-half the diagonal distance between detectors). As noted in A.9.2.5.4.4.1, detectors have an activation temperature of 31°C (10°C above ambient) and are located 0.1 m below the ceiling.

The vent design will use sixteen 1.76 m^2 vents located 18.3 m on center. All vents automatically open on activation of the first smoke detector.

LAVENT predicts that the upper-layer temperature will be 377°C and that the upper "hot" layer will be 4.6 m above floor level at 600 seconds. A 3 m clear layer is maintained throughout the 600 second time interval. However, heat flux at floor level is projected to be approximately 10 kW/m^2 at 600 seconds, and the design objective of limiting heat flux to 2.5 kW/m^2 at floor level is exceeded. At 342 seconds, the time of detection plus 300 seconds, however, the design objectives are met. At 360 seconds, LAVENT predicts the upper-layer temperature as 444 K (171°C), with the layer being 7.3 m above the floor. The predicted 150 K temperature rise is limited to less than the target value of 164 K, and heat flux at floor level is predicted to be 2.2 kW/m^2. Therefore, the design objectives are satisfied for a time interval greater than the time of detection plus 300 seconds.

Inlet air is 1.5 times the vent area. To maintain the vent flow predicted by LAVENT, inlet air net free area should be maintained at a minimum of twice the open vent area. Although the net free inlet air area is less than required, the inlet area is sufficiently large that LAVENT predictions can be assumed to be reasonably valid. However, consideration should be given to increasing the vent area to account for the restrictions in inlet air.

See Figure D.10(a) through Figure D.10(h) for results of the program, and Figure D.10(i) for a computer printout of the LAVENT output.

Annex E Predicting the Rate of Heat Release of Fires

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

E.1 Introduction. Annex E presents techniques for estimating the heat release rate of various fuel arrays likely to be present in buildings where smoke and heat venting is a potential fire safety provision. This annex primarily addresses the estimation of fuel concentrations found in storage and manufacturing locations. NFPA 92 addresses the types of fuel arrays more common to the types of building situations covered by that document.

This standard is applicable to situations in which the hot layer does not enhance the burning rate. The methods provided in this annex for estimating the rate of heat release, therefore, are based on free burning conditions in which no ceiling or hot gas layer effects are involved. It is assumed, therefore, that the burning rate is relatively unaffected by the hot layer.

E.2 Sources of Data. The following sources of data appear in their approximate order of priority, given equal quality of data acquisition:

(1) Actual tests of the array involved
(2) Actual tests of similar arrays
(3) Algorithms derived from tests of arrays having similar fuels and dimensional characteristics
(4) Calculations based on tested properties and materials and expected flame flux
(5) Mathematical models of fire spread and development

E.3 Actual Tests of the Array Involved. Where an actual calorific test of the specific array under consideration has been conducted and the data are in a form that can be expressed as rate of heat release, the data can be used as input for the methods in this standard. Because actual test data seldom produce the steady state assumed for a limited-growth fire or the square-of-time growth assumed for a continuous-growth fire, engineering judgment is usually needed to derive the actual input necessary if either of these approaches is used. If LAVENT or another computer model capable of responding to a rate of heat release versus time curve is used, the data can be used directly. Currently there is a listing of limited information from tests of specific arrays. Some test data can be found in technical reports. Alternatively, individual tests can be conducted.

Many fire tests do not include a direct measurement of rate of heat release. In some cases, that measure can be derived, based on measurement of mass loss rate using the following equation:

$$Q = m\left(h_c\right) \quad \textbf{[E.3a]}$$

where:
Q = total heat release rate (kW)
m = mass loss rate (kg/s)
h_c = heat of combustion (kJ/kg)

In other cases, a direct measurement can be derived based on measurement of flame height above the base of the fire as follows:

$$Q = 37\left(L + 1.02D\right)^{5/2} \quad \textbf{[E.3b]}$$

where:
Q = total heat release rate (kW)
L = mean flame height above the base of the fire (m)
D = base diameter of the fire (m)

E.4 Actual Tests of Arrays Similar to That Involved. Where an actual calorific test of the specific array under consideration cannot be found, it might be possible to find data on one or more tests that are similar to the fuel of concern in important matters such as type of fuel, arrangement, or ignition scenario. The more the actual tests are similar to the fuel of concern, the higher is the confidence that can be placed in the derived rate of heat release. Added engineering judgment, however, might be needed to adjust the test data to that approximating the fuel of concern. If the rate of heat release has not been measured directly, it can be estimated using the methods provided in Section E.3.

E.5 Algorithms Derived from Tests of Arrays Having Similar Fuels and Dimensional Characteristics.

E.5.1 Pool Fires. In many cases, the rate of heat release of a tested array has been divided by a common dimension, such as occupied floor area, to derive a normalized rate of heat release per unit area. The rate of heat release of pool fires is the best documented and accepted algorithm in this class.

An equation for the mass release rate from a pool fire is as follows [Babrauskas, 2008]:

$$\dot{m}'' = \dot{m}''_{\infty}\left(1 - e^{-(k_e\beta)D}\right) \qquad \textbf{[E.5.1]}$$

The variables $\dot{m}''_{\infty}$ and $(k_e\beta)^D$ for Equation E.5.1 are as shown in Table E.5.1.

The mass rates derived from Equation E.5.1 are converted to rates of heat release using Equation E.3a and the heat of combustion, h_c, from Table E.5.1. The rate of heat release per unit area times the area of the pool yields heat release data for the anticipated fire.

E.5.2 Other Normalized Data. Other data based on burning rate per unit area in tests have been developed. Table E.5.2(a) and Table E.5.2(b) list these data.

E.5.3 Other Useful Data. Examples of other data that are not normalized but that might be useful in developing the rate of heat release curve are included in Table E.5.3(a) through Table E.5.3(d).

E.6 Calculated Fire Description Based on Tested Properties.

E.6.1 Background. It is possible to make general estimates of the rate of heat release of burning materials based on the fire properties of that material. The fire properties involved are determined by small-scale tests. The most important of these tests are the calorimeter tests involving both oxygen depletion calorimetry and the application of external heat flux to the sample while determining time to ignition, rate of mass release, and rate of heat release for the specific applied flux. Most prominent of the current test apparatus are the cone calorimeter (ASTM E 1354, *Standard Test Method for Heat and Visible Smoke Release Rates for Materials and Products Using an Oxygen Consumption Calorimeter*) and the Factory Mutual Fire Propagation Apparatus [ASTM E 2058, *Standard Test Methods for Measurement of Synthetic Polymer Material Flammability Using a Fire Propagation Apparatus (FPA)*].

In addition to the directly measured properties, it is possible to derive ignition temperature, critical ignition flux, effective thermal inertia (kc), heat of combustion, and heat of gasification based on results from these calorimeters. Properties not derivable from these calorimeters and essential to determining flame spread in directions not concurrent with the flow of the flame can be obtained from the LIFT (lateral ignition and flame travel) apparatus (ASTM E 1321, *Standard Test Method for Determining Material Ignition and Flame Spread Properties*).

This section presents a concept of the use of fire property test data as the basis of an analytical evaluation of the rate of

Table E.5.1 Data for Large Pool Burning Rate Estimates

Material	Density (kg/m^3)	h_c (MJ/kg)	$\dot{m}''_{\infty}$	$k_e\beta^D$ (m^{-1})

[c] Estimate is uncertain, since only two data points are available.

Table E.5.2(a) Unit Heat Release Rates for Fuels Burning in the Open

Commodity	Heat Release Rate (kW)
Wood or PMMA* (vertical)	
0.61 m height	100/m of width
1.83 m height	240/m of width
2.44 m height	620/m of width
3.66 m height	1000/m of width
Wood or PMMA	
Top of horizontal surface	720/m^2 of surface
Solid polystyrene (vertical)	
0.61 m height	220/m of width
1.83 m height	450/m of width
2.44 m height	1400/m of width
3.66 m height	2400/m of width
Solid polystyrene (horizontal)	1400/m^2 of surface
Solid polypropylene (vertical)	
0.61 m height	220/m of width
1.83 m height	350/m of width
2.44 m height	970/m of width
3.66 m height	1600/m of width
Solid polypropylene (horizontal)	800/m^2 of surface

* PMMA: polymethyl methacrylate (Plexiglas, Lucite, acrylic).

Table E.5.2(b) Unit Heat Release Rate for Commodities

Commodity	Heat Release Rate (kW per m^2 of floor area)*
Wood pallets, stacked 0.46 m high (6%–12% moisture)	1,420
Wood pallets, stacked 1.52 m high (6%–12% moisture)	4,000
Wood pallets, stacked 3.05 m high (6%–12% moisture)	6,800
Wood pallets, stacked 4.88 m high (6%–12% moisture)	10,200
Mail bags, filled, stored 1.52 m high	400
Cartons, compartmented, stacked 4.5 m high	1,700
PE letter trays, filled, stacked 1.5 m high on cart	8,500
PE trash barrels in cartons, stacked 4.5 m high	2,000
PE fiberglass shower stalls in cartons, stacked 4.6 m high	1,400
FRP bottles packed in cartons, stacked 4.6 m high	6,200
PE bottles in cartons, stacked 4.5 m high	2,000
PU insulation board, rigid foam, stacked 4.6 m high	1,900
FRP jars packed in cartons, stacked 4.6 m high	14,200
PS tubs nested in cartons, stacked 4.2 m high	5,400
PS toy parts in cartons, stacked 4.5 m high	2,000
PS insulation board, rigid foam, stacked 4.2 m high	3,300
FRP bottles packed in cartons, stacked 4.6 m high	3,400
FRP tubs packed in cartons, stacked 4.6 m high	4,400
PP and PE film in rolls, stacked 4.1 m high	6,200
Methyl alcohol	600
Gasoline	2,500
Kerosene	1,700
Fuel oil, no. 2	1,700

PE: polyethylene. PP: polypropylene. PS: polystyrene. PU: polyurethane. FRP: fiberglass-reinforced polyester.
*Heat release rate per unit floor area of fully involved combustibles, based on negligible radiative feedback from the surroundings and 100 percent combustion efficiency.

Table E.5.3(a) Characteristics of Ignition Sources

Fuel	Typical Heat Output (W)	Burn Time[a] (s)	Maximum Flame Height (mm)	Flame Width (mm)	Maximum Heat Flux (kW/m²)
Cigarette 1.1 g (not puffed, laid on solid surface)					
Bone dry	5	1,200	—	—	42
Conditioned to 50% relative humidity	5	1,200	—	—	35
Methenamine pill, 0.15 g	45	90	—	—	4
Match, wooden (laid on solid surface)	80	2030	30	14	18–20
Wood cribs, BS 5852 Part 2

[a]Estimated from mass loss records and assumed Wh_c.
[b]Estimated from doorway gas concentrations.

heat release involved in the use of a tested material. The approach outlined in this section is based on that presented by Nelson and Forssell [1994].

E.6.2 Discussion of Measured Properties. Table E.6.2(a) lists the type of fire properties obtainable from the cone calorimeter [NFPA 287], the Factory Mutual Fire Propagation Apparatus [ASTM E 2058, *Standard Test Methods for Measurement of Synthetic Polymer Material Flammability Using a Fire Propagation Apparatus (FPA)*], and similar instruments.

In Table E.6.2(a), the rate of heat release, mass loss, and time to ignition are functions of the externally applied incident radiant heat flux imposed on the tested sample. The purpose of the externally applied flux is to simulate the fire environment surrounding a burning item.

In general, it can be estimated that a free-burning fuel package (i.e., one that burns in the open and is not affected by energy feedback from a hot gas layer of a heat source other than its own flame) is impacted by a flux in the range of 25 kW/m^2 to 50 kW/m^2. If the fire is in a space and conditions are approaching flashover, the flux can increase to the range of 50 kW/m^2 to 75 kW/m^2. In a fully developed, postflashover fire, a range of 75 kW/m^2 to greater than 100 kW/m^2 can be expected. The following is a discussion of the individual properties measured or derived and the usual form used to report the property.

Table E.6.2(a) Relation of Calorimeter-Measured Properties to Fire Analysis

Property	Ignition	Flame Spread	Fire Size (energy)
Rate of heat release*		X	X
Mass loss*			X
Time to ignition*	X	X	
Effective thermal properties†	X	X	
Heat of combustion†		X	X
Heat of gasification†			X
Critical ignition flux†	X	X	
Ignition temperature†	X	X	

*Property is a function of the externally applied incident flux.
†Derived properties from calorimeter measurements.

Rate of Heat Release. The rate of heat release is determined by oxygen depletion calorimetry. Each test is run at a user-specific incident flux, either for a predetermined period of time or until the sample is consumed. The complete results are presented in the form of a plot of heat release rate versus time, with the level of applied flux noted. In some cases, the rate of heat release for several tests of the same material at different levels of applied flux is plotted on a single curve for comparison. Figure E.6.2 is an example of such a plotting.

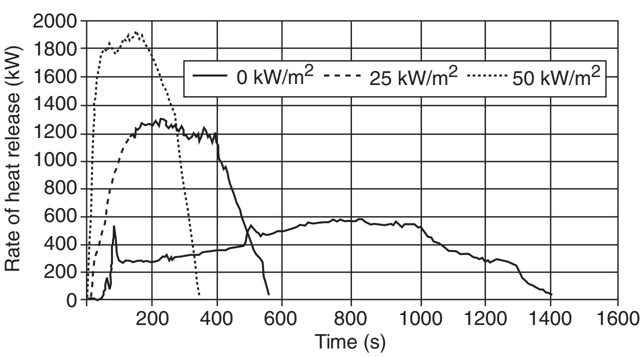

FIGURE E.6.2 Typical Graphic Output of Cone Calorimeter Test.

Often, only the peak rate of heat release at a specific flux is reported. Table E.6.2(b) is an example.

Mass Loss Rate. Mass loss rate is determined by a load cell. The method of reporting is identical to that for rate of heat release. In the typical situation in which the material has a consistent heat of combustion, the curves for mass loss rate and rate of heat release are similar in shape.

Time to Ignition. Time to ignition is reported for each individual test and applied flux level conducted.

Effective Thermal Inertia ($k\rho c$). Effective thermal inertia is a measurement of the heat rise response of the tested material to the heat flux imposed on the sample. It is derived at the time of ignition and is based on the ratio of the actual incident flux to the critical ignition flux and the time to ignition. A series of tests at different levels of applied flux is necessary to derive the effective thermal inertia. Effective thermal inertia derived in this manner can differ from, and be preferable to,

Table E.6.2(b) Average Maximum Heat Release Rates (kW/m2)

Material	Orientation	25 kW/m² Exposing Flux	50 kW/m² Exposing Flux	75 kW/m² Exposing Flux
PMMA	Horizontal	650	900	1300
	Vertical	560	720	1300
Pine	Horizontal	140	240	265
	Vertical	130	170	240
Sample A	Horizontal	125	200	250
	Vertical	90	130	220
Sample B	Horizontal	140	175	240
	Vertical	60	200	330
Sample C	Horizontal		215	250
	Vertical		165	170
Sample D	Horizontal	70	145	145
	Vertical		125	125

handbook data for the values of k, ρ, and c that are derived without a fire.

Heat of Combustion. Heat of combustion is derived by dividing the measured rate of heat release by the measured mass loss rate. It is normally reported as a single value, unless the sample is a composite material and the rates of heat release and mass loss vary significantly with time and exposure.

Heat of Gasification. Heat of gasification is the flux needed to pyrolyze a unit mass of fuel. It is derived as a heat balance and is usually reported as a single value in terms of the amount of energy per unit mass of material released (e.g., kJ/g).

Critical Ignition Flux. Critical ignition flux is the minimum level of incident flux on the sample needed to ignite the sample, given an unlimited time of application. At incident flux levels less than the critical ignition flux, ignition does not take place.

Ignition Temperature. Ignition temperature of a sample is the surface temperature at which flame occurs. This sample material value is independent of the incident flux and is derivable from the calorimeter tests, the LIFT apparatus test, and other tests. It is derived from the time to ignite in a given test, the applied flux in that test, and the effective thermal inertia of the sample. It is reported at a single temperature. If the test includes a pilot flame or spark, the reported temperature is for piloted ignition; if there is no pilot present, the temperature is for auto-ignition. Most available data are for piloted ignition.

E.6.3 Ignition. Equations for time to ignition, t_{ig}, are given for both thermally thin and thermally thick materials, defined as follows. For materials of intermediate depth, estimates for t_{ig} necessitate considerations beyond the scope of this presentation [Drysdale, 2011, Carslaw and Jaeger, 1959].

Thermally Thin Materials. Relative to ignition from a constant incident heat flux, q_i, at the exposed surface and with relatively small heat transfer losses at the unexposed surface, a thermally thin material is one whose temperature is relatively uniform throughout its entire thickness, l, at $t = t_{ig}$. For example, at $t = t_{ig}$:

$$T_{exposed} - T_{unexposed} = T_{ig} - T_{unexposed} < 0.1\left(T_{ig} - T_o\right) \quad \textbf{[E.6.3a]}$$

Equation E.6.3a can be used to show that a material is thermally thin [Carslaw and Jaeger, 1959] where:

$$l < 0.6\left(t_{ig}\alpha\right)^{1/2} \qquad \textbf{[E.6.3b]}$$

For example, for sheets of maple or oak wood (where the thermal diffusivity = $1.28\ 10^{7}\ m^2/s$ [DiNenno et al., 1995]), if t_{ig} = 35 s is measured in a piloted ignition test, then, according to Equation E.6.3b, if the sample thickness is less than approximately 0.0013 m, the unexposed surface of the sample can be expected to be relatively close to T_{ig} at the time of ignition, and the sample is considered to be thermally thin.

The time to ignition of a thermally thin material subjected to incident flux above a critical incident flux is as follows:

$$t_{ig} = \rho c l \frac{\left(T_{ig} - T_o\right)}{\dot{q}''_i} \qquad \textbf{[E.6.3c]}$$

Thermally Thick Materials. Relative to the type of ignition test described for thermally thin materials, a sample of a material of a thickness, *l*, is considered to be thermally thick if the increase in temperature of the unexposed surface is relatively small compared to that of the exposed surface at $t = t_{ig}$. For example, at $t = t_{ig}$,

$$T_{unexposed} - T_o < 0.1\left(T_{exposed} - T_o\right) = 0.1\left(T_{ig} - T_o\right) \qquad \textbf{[E.6.3d]}$$

Equation E.6.3d can be used to show that a material is thermally thick [Carslaw and Jaeger, 1959] where:

$$l > 2\left(t_{ig}\alpha\right)^{1/2} \qquad \textbf{[E.6.3e]}$$

For example, according to Equation E.6.3e, in the case of an ignition test on a sheet of maple or oak wood, if t_{ig} = 35 s is measured in a piloted ignition test and if the sample thickness is greater than approximately 0.0042 m, the unexposed surface of the sample can be expected to be relatively close to T_o at the time of ignition, and the sample is considered to be thermally thick.

Time to ignition of a thermally thick material subjected to incident flux above a critical incident flux is as follows:

$$t_{ig} = \frac{\pi}{4} k \rho c \left(\frac{T_{ig} - T_o}{\dot{q}''_i}\right)^2 \qquad \textbf{[E.6.3f]}$$

It should be noted that a particular material is not intrinsically thermally thin or thick (i.e., the characteristic of being thermally thin or thick is not a material characteristic or property), but rather depends on the thickness of the particular sample (i.e., a particular material can be implemented in either a thermally thick or a thermally thin configuration).

Propagation between Separate Fuel Packages. Where the concern is for propagation between individual, separated fuel packages, incident flux can be calculated using traditional radiation heat transfer procedures [Tien, et al., 2008].

The rate of radiation heat transfer from a flaming fuel package of total energy release rate, *Q*, to a facing surface element of an exposed fuel package can be estimated from the following equation:

$$\dot{q}''_i = \frac{\chi_r}{4\pi r^2} \qquad \textbf{[E.6.3g]}$$

E.6.4 Estimating Rate of Heat Release. As discussed in E.6.2, tests have demonstrated that the energy feedback from a burning fuel package ranges from approximately 25 kW/m^2 to 50 kW/m^2. For a reasonably conservative analysis, it is recommended that test data developed with an incident flux of 50 kW/m^2 be used. For a first-order approximation, it should be assumed that all of the surfaces that can be simultaneously involved in burning are releasing energy at a rate equal to that determined by testing the material in a fire properties calorimeter with an incident flux of 50 kW/m^2 for a free-burning material and 75 kW/m^2 to 100 kW/m^2 for postflashover conditions.

In making this estimate, it is necessary to assume that all surfaces that can "see" an exposing flame (or superheated gas, in the postflashover condition) are burning and releasing energy and mass at the tested rate. If sufficient air is present, the rate of heat release estimate is then calculated as the product of the exposed area and the rate of heat release per unit area as determined in the test calorimeter. Where test data are taken at the incident flux of the exposing flame, the tested rate of heat release should be used. Where the test data are for a different incident flux, the burning rate should be estimated using the heat of gasification as expressed in Equation E.6.4a to calculate the mass burning rate per unit area.

$$\dot{m}'' = \frac{\dot{q}''_i}{h_g} \qquad \textbf{[E.6.4a]}$$

The resulting mass loss rate is then multiplied by the derived effective heat of combustion and the burning area exposed to the incident flux to produce the estimated rate of heat release as follows:

$$Q = \dot{m}'' h_c A \qquad \textbf{[E.6.4b]}$$

E.6.5 Flame Spread. If it is desired to predict the growth of fire as it propagates over combustible surfaces, it is necessary to estimate flame spread. The computation of flame spread rates is an emerging technology still in an embryonic stage. Predictions should be considered as order of magnitude estimates.

Flame spread is the movement of the flame front across the surface of a material that is burning (or exposed to an ignition flame), but whose exposed surface is not yet fully involved. Physically, flame spread can be treated as a succession of ignitions resulting from the heat energy produced by the burning portion of a material, its flame, and any other incident heat energy imposed on the unburned surface. Other sources of incident energy include another burning object, high-temperature gases that can accumulate in the upper portion of an enclosed space, and the radiant heat sources used in a test apparatus such as the cone calorimeter or the LIFT mechanism.

For analysis purposes, flame spread can be divided into the following two categories:

(1) Concurrent, or wind-aided, flame spread, which moves in the same direction as the flame
(2) Lateral, or opposed, flame spread, which moves in any other direction

Concurrent flame spread is assisted by the incident heat flux from the flame to unignited portions of the burning material. Lateral flame spread is not so assisted and tends to be much slower in progression unless an external source of heat flux is present. Concurrent flame spread for thermally thick materials can be expressed as follows:

$$V = \frac{\left(\dot{q}''_i\right)^2 L_f}{k \rho c \left(T_{ig} - T_s\right)^2} \qquad \textbf{[E.6.5]}$$

The values for $k\rho c$ and ignition temperature are calculated from the cone calorimeter as discussed. For this equation, the flame length, L_f, is measured from the leading edge of the burning region, and T_s is the initial temperature of the solid material.

E.6.6 Classification of Fires for Engineering Equations. The engineering equations in Chapter 8 are appropriate for steady fires, limited-growth fires, and *t*-squared forms of continuous-growth fires.

Annex F Design Information

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

F.1 Growth times for combustible arrays have been obtained *[see Table F.1(a)]*. These are specified for certain storage heights.

Actual tests [Yu and Stavrianidis, 1991] have demonstrated that it is reasonable to assume that the instantaneous heat release rate per unit height of the storage array is insensitive to the storage height. Such behavior corresponds to the growth time, t_g, being inversely proportional to the square root of the storage height. Alternatively, it corresponds to the fire growth coefficient, α_g, being directly proportional to the storage height. For example, if the storage height is one-third the tested height, the growth time is $[1/(⅓)]^{1/2}$ = 1.73 times the growth time from the test. If the storage height is three times the tested height, the growth time is $(⅓)^{1/2}$ = 0.58 times the growth time from the test. For fuel configurations that have not been tested, the procedures discussed in Annex E might be applicable.

t-Squared Fires. Over the past decade, those interested in developing generic descriptions of the rate of heat release of accidental open flaming fires have used a *t-squared* approximation for this purpose. A *t*-squared fire is one in which the burning rate varies proportionally to the square of time. Frequently, *t*-squared fires are classified by their speed of growth as fast, medium, or slow (and occasionally ultra-fast). Where these classes are used, they are determined by the time needed for the fire to grow to a rate of heat release of 1000 kW. The times for each of these classes are provided in Table F.1(b). For many fires involving storage arrays, the time to reach 1000 kW might be much shorter than the 75 seconds depicted for ultra-fast fires.

The general equation is as follows:

$$Q = \alpha_g t^2 \quad \textbf{[F.1]}$$

where:

Q = rate of heat release (kW)

α_g = a constant describing the speed of growth (kW/s^2)

t = time (s)

A *t*-squared fire can be viewed as a fire in which the rate of heat release per unit area is constant over the entire ignited surface, and in which the fire spreads in circular form with a steadily increasing radius. In such cases, the increase in the burning area is the square of the steadily increasing fire radius. Of course, other fires that do not have such a conveniently regular fuel array and consistent burning rate might or might not actually produce a *t*-squared curve. The tacit assumption is that the *t*-squared approximation is close enough for reasonable design decisions.

Table F.1(a) Continuous-Growth Fires

Fuel	Growth Time* (s)
Wood pallets, stacked 0.46 m high (6%–12% moisture)	160–320
Wood pallets, stacked 1.52 m high (6%–12% moisture)	90–190
Wood pallets, stacked 3.05 m high (6%–12% moisture)	80–120
Wood pallets, stacked 4.88 m high (6%–12% moisture)	75–120
Mail bags, filled, stored 1.52 m high	190
Cartons, compartmented, stacked 4.57 m high	60
Paper, vertical rolls, stacked 6.10 m high	17–28
Cotton (also PE, PE/cot acrylic/nylon/PE), garments in 3.66 m high rack	22–43
Ordinary combustibles rack storage, 4.57 m–9.14 m high	40–270
Paper products, densely packed in cartons, rack storage, 6.10 m high	470
PE letter trays, filled, stacked 1.52 m high on cart	180
PE trash barrels in cartons, stacked 4.57 m high	55
FRP shower stalls in cartons, stacked 4.57 m high	85
PE bottles packed in compartmented cartons, stacked 4.57 m high	85
PE bottles in cartons, stacked 4.57 m high	75
PE pallets, stacked 0.91 m high	150
PE pallets, stacked 1.83 m–2.44 m high	32–57
PU mattress, single, horizontal	120
PU insulation board, rigid foam, stacked 4.57 m high	8
PS jars packed in compartmented cartons, stacked 4.57 m high	55
PS tubs nested in cartons, stacked 4.27 m high	110
PS toy parts in cartons, stacked 4.57 m high	120
PS insulation board, rigid foam, stacked 4.27 m high	7
PVC bottles packed in compartmented cartons, stacked 4.57 m high	9
PP tubs packed in compartmented cartons, stacked 4.57 m high	10
PP and PE film in rolls, stacked 4.27 m high	40
Distilled spirits in barrels, stacked 6.10 m high	25–40

FRP: fiberglass-reinforced polyester. PE: polyethylene. PP: polypropylene. PS: polystyrene. PU: polyurethane. PVC: polyvinyl chloride.

*Growth times of developing fires in various combustibles, assuming 100 percent combustion efficiency.

Table F.1(b) Classifications of t-Squared Fires

Class	Time to Reach 1000 kW (s)
Ultra-fast	75
Fast	150
Medium	300
Slow	600

Figure 8.3.1 demonstrates that most fires have an incubation period during which the fire does not conform to a *t*-squared approximation. In some cases, this incubation period might be a serious detriment to the use of the *t*-squared approximation. In most instances, this is not a serious concern in large spaces covered by this standard. It is expected that the rate of heat release during the incubation period will not usually be sufficient to cause activation of the smoke detection system. In any case, where such activation occurs, or where human observation results in earlier activation of the smoke-venting system, a fortuitous safeguard will result.

Figure F.1(a) compares rate of heat release curves developed by the aforementioned classes of *t*-squared fires and two test fires commonly used for test purposes. The test fires are shown as dashed lines labeled as furniture and 6 ft storage. The dashed curves farther from the fire origin show the actual rates of heat release of the test fires used in the development of the residential sprinkler and a standard 6 ft high array of test cartons containing foam plastic pails that also are frequently used as a standard test fire.

The other set of dashed lines in Figure F.1(a) shows these same fire curves relocated to the origin of the graph. This is a more appropriate comparison with the generic curves. It can be seen that the rate of growth in these fires is actually faster than that prescribed for an ultra-fast fire. This is appropriate for a test fire designed to challenge the fire suppression system being tested.

Figure F.1(b) relates the classes of *t*-squared fire growth curves to a selection of actual fuel arrays.

F.2 For consistency with Annex B and with referenced documents on the fire model LAVENT, the nomenclature for this section differs from that of the other section in this annex. The definitions for the variables used in this section are provided in Section B.7.

A ceiling vent design is successful to the extent that it controls a fire-generated environment developing in a space of fire origin according to any of a variety of possible specified criteria. For example, if the likely growth rate of a fire in a particular burning commodity is known, a vent system with a large enough vent area, designed to provide for timely opening of the vents, can be expected to lead to rates of smoke removal that are so large that fire fighters, arriving at the fire at a specified time subsequent to fire detection, are able to attack the fire successfully and protect commodities in adjacent spaces from being damaged.

To evaluate the success of a particular design, it is necessary to predict the development of the fire environment as a function of any of a number of physical characteristics that define and might have a significant effect on the fire scenario. Examples of such characteristics include the following:

(1) The floor-to-ceiling height and area of the space and the thermal properties of its ceiling, walls, and floor
(2) The type of barriers that separate the space of fire origin and adjacent spaces (e.g., full walls with vertical door-like vents or ceiling-mounted draft curtains)
(3) The material type and arrangement of the burning commodities (e.g., wood pallets in plan-area arrays of 3 m × 3 m and stacked 2 m high)
(4) The type, location, and method of deployment of devices that detect the fire and actuate the opening of the vents (e.g., fusible links of specified RTI and distributed at a specified spacing distance below the ceiling)
(5) The size of the open area of the vents themselves

The best way to predict the fire environment and evaluate the likely effectiveness of a vent design is to use a reliable mathematical model that simulates the various relevant physical phenomena that come into play during the fire scenario. Such an analytical tool should be designed to solve well-formulated mathematical problems, based on basic relevant principles of physics and on fundamentally sound, well-established, empirical relationships. Even in the case of a particular class of problem, such as an engineering problem associated with successful vent design, there is a good deal of variation among applicable mathematical models that could be developed to carry out the task. Such models might differ from one another in the number and detail of the individual physical phenomena taken into account. Therefore, the list of physical characteristics that define and could have a significant effect on the fire scenario does not include outside wind conditions, which could have an important influence on the fire-generated environment. A model might or might not include the effect of wind. A model that does include the effect

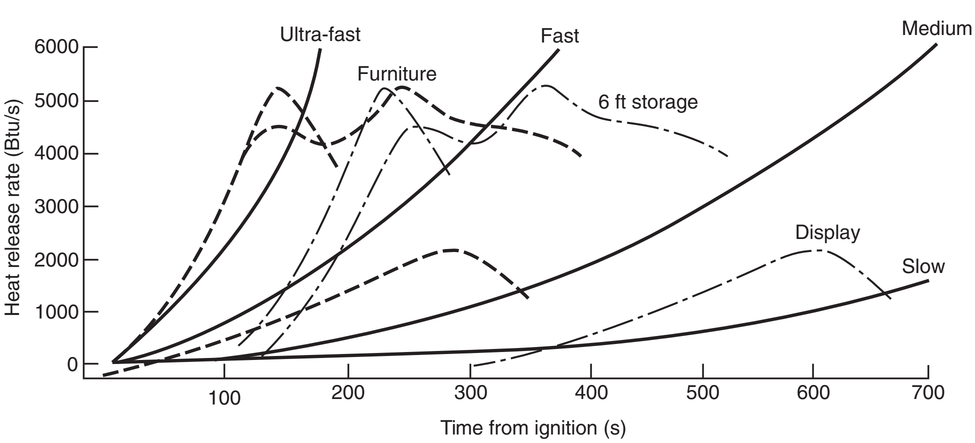

FIGURE F.1(a) Rates of Energy Release for *t*-Squared Fire. (Redrawn from NIST, 1987.)

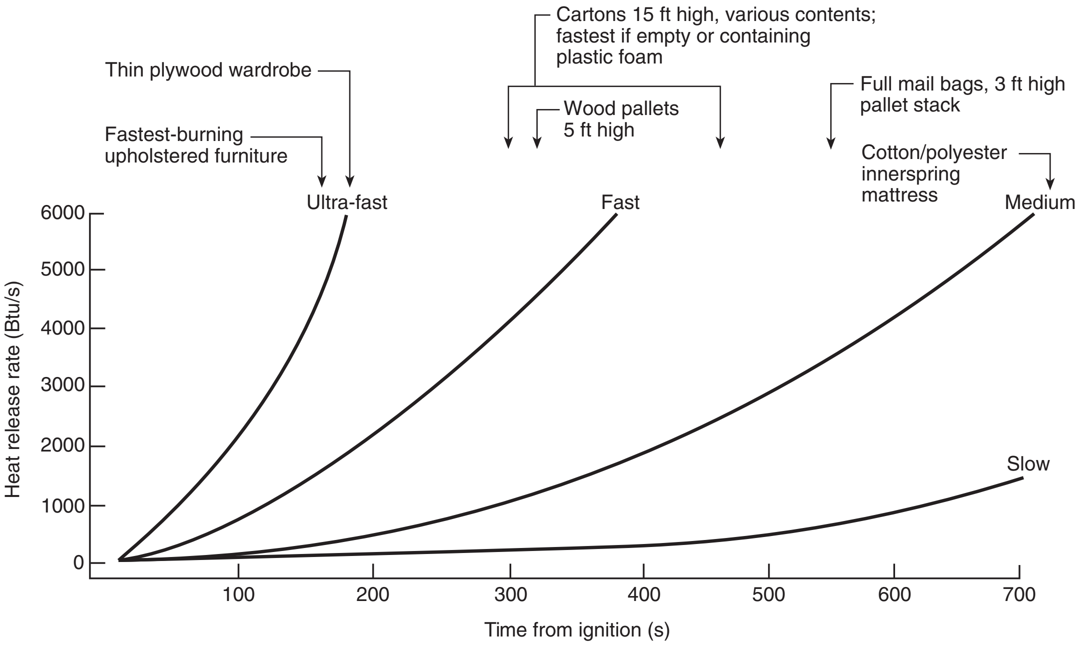

FIGURE F.1(b) Relation of *t*-Squared Fires to Some Fire Tests.

of wind is more difficult to develop and validate and is more complicated to use. Note that the effect of wind is not taken into account in the following discussion of the LAVENT model. However, by using reasonably well-accepted mathematical modeling concepts, LAVENT could be developed to the point that it could be used to simulate this effect.

The discussion that follows describes a group of phenomena that represent a physical basis for estimating the fire-generated environment and the response of heat-responsive elements in well-ventilated compartment fires with draft curtains and ceiling vents activated by fusible links, thermoplastic drop-out panels, or other alternative means of activation or smoke detectors. The phenomena include the following:

(1) Growth of the smoke layer in the curtained area
(2) The flow dynamics of the buoyant fire plume
(3) The flow of smoke through open ceiling vents
(4) The flow of smoke below draft curtains
(5) Continuation of the fire plume in the upper layer
(6) Heat transfer to the ceiling surface and the thermal response of the ceiling
(7) The velocity and temperature distribution of plume-driven, near-ceiling flows
(8) The response of near-ceiling deployed heat-responsive elements and smoke detectors

All the phenomena in items (1) through (8) are taken into account in the LAVENT model, which was developed to simulate well-ventilated compartment fires with draft curtains and fusible link-actuated or smoke detector–actuated ceiling vents. Other models that could be developed for a similar purpose typically would also be expected to simulate these basic phenomena.

The space to be considered is defined by ceiling-mounted draft curtains with a fire and with near-ceiling fusible link-actuated ceiling vents and sprinklers. The curtained area should be considered as one of several such spaces in a large building area. Also, by specifying that the curtains be deep enough, they can be thought of as simulating the walls of a single uncurtained area.

This section discusses critical physical phenomena that determine the overall environment in the curtained space up to the time of sprinkler actuation. The objective is to identify and describe the phenomena in a manner that captures the essential features of this generic class of fire scenario and that allows for a complete and general, but concise and relatively simple, mathematical/computer simulation.

The overall building area is assumed to have near-floor inlet air openings that are large enough to maintain the inside environment, below any near-ceiling smoke layers that might form, at outside-ambient conditions. Figure F.2(a) depicts the generic fire scenario considered. It is assumed that a two-layer zone-type model adequately describes the phenomena under investigation. The lower layer is identical to the outside ambient. The upper smoke layer thickness and properties change with time, but the layer is assumed to be uniform in space at any time. Conservation of energy and mass along with the perfect gas law is applied to the upper layer. This leads to equations that necessitate estimates of the net rate of enthalpy flow plus heat transfer and the net rate of mass flow to the upper layer. Qualitative features of the phenomena that contribute to these flows and heat transfer are described briefly.

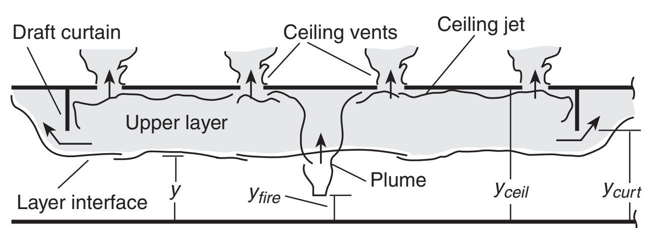

FIGURE F.2(a) LAVENT Model: Fire in a Building Space with Draft Curtains and Ceiling Vents.

Flow is driven through ceiling vents by cross-vent hydrostatic pressure differences. The traditional calculation uses orifice-type flow calculations. Bernoulli's equation is applied across a vent, and it is assumed that, away from and on either side of the vent, the environment is relatively quiescent. Figure F.2(b) depicts the known, instantaneous, hydrostatic pressure distribution in the outside environment and throughout the depth of the curtained space. These pressures are used to calculate the resulting cross-vent pressure difference, then the actual instantaneous mass and enthalpy flow rates through a vent.

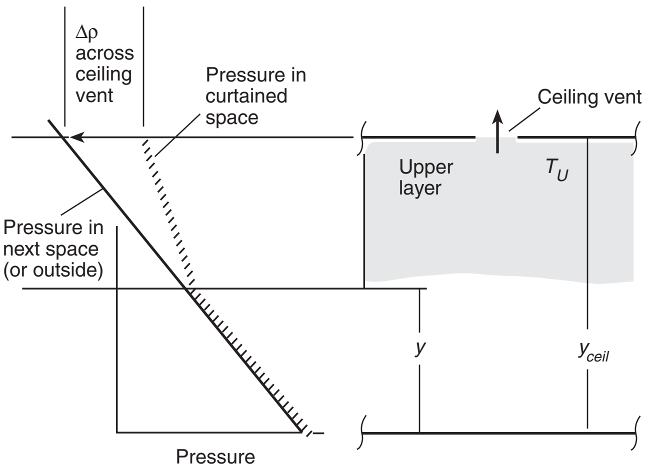

FIGURE F.2(b) Flow Through a Ceiling Vent.

If and when the smoke layer boundary face drops below the bottom of the draft curtains, the smoke starts to flow out of the curtained space. As with the ceiling vents, this flow rate is determined by the cross-vent hydrostatic pressure difference. As depicted in Figure F.2(c), however, the pressure difference in this case is not constant across the flow. Nonetheless, even in this configuration, the instantaneous flow rates are easily determined with well-known vertical-vent flow equations used traditionally in zone-type fire models.

The major contributors to the upper-layer flow and surface heat transfer are the fire and its plume. These properties are depicted in Figure F.2(d). It is assumed that the rate of energy

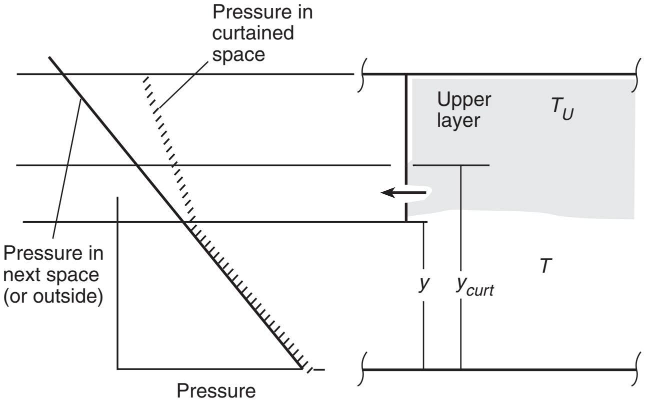

FIGURE F.2(c) Flow Below a Draft Curtain.

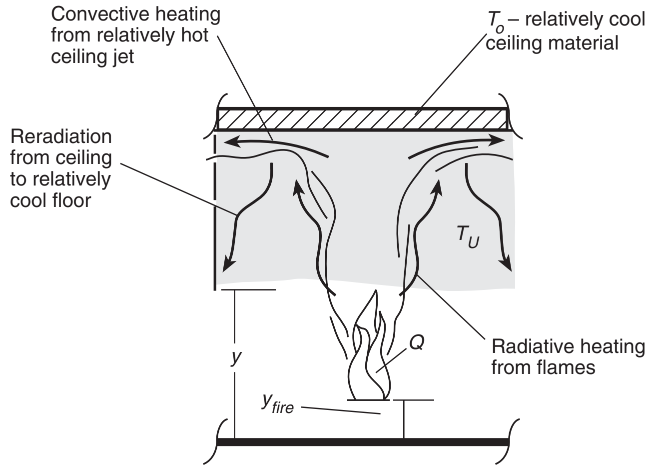

FIGURE F.2(d) The Fire, the Fire Plume, and Heat Transfer to the Ceiling.

release of the fire's combustion zone does not vary significantly from known free-burn values that are available and assumed to be specified *(see Chapter 8)*. A known, fixed fraction of this energy is assumed to be radiated isotropically, as in the case of a point source, from the combustion zone. The smoke layer is assumed to be relatively transparent (i.e., all radiation from the fire is incident on the bounding surfaces of the compartment).

A plume model, selected from the several available in the literature, is used to determine the rate of mass and enthalpy flow in the plume at the elevation of the smoke layer boundary. It is assumed that all of this flow penetrates the smoke layer boundary and enters the upper layer. As the plume flow enters the upper layer, the forces of buoyancy that act to drive the plume toward the ceiling are reduced immediately because of the temperature increase of the upper-layer environment over that of the lower ambient. As a result, the continued ascent of the plume gases is less vigorous (i.e., is at a reduced velocity) than it would be in the absence of the layer. Also, as the plume gases continue their ascent, the temperature becomes higher than it would be without the upper layer. Such higher temperatures are a result of the modified plume entrainment, which is now occurring in the relatively high-temperature upper layer rather than in the ambient-temperature lower layer. Methods of predicting the characteristics of the modified upper-plume flow are available.

Having penetrated the smoke layer boundary, the plume continues to rise toward the ceiling of the curtained area. As it impinges on the ceiling surface, the plume flow turns and forms a relatively high-temperature, high-velocity, turbulent-ceiling jet that flows radially outward along the ceiling and transfers heat to the relatively cool ceiling surface. The ceiling jet is cooled by convection, and the ceiling material is heated by conduction. Eventually, the now-cooled ceiling jet reaches the extremities of the curtained space and is deposited into and mixed with the upper layer. The convective heat transfer rate and the ceiling surface temperature on which it depends are both strong functions of the radial distance from the point of plume–ceiling impingement, and both decrease rapidly with increasing radius.

The thermal response of the ceiling is driven by transient heat conduction. For the time period typically considered, radial gradients in ceiling surface conditions are small enough so that the conduction heat transfer is quasi–one dimensional in space. Therefore, the thermal response of the ceiling can be obtained from the solution to a set of one-dimensional conduction problems at a few discrete radial positions. These problems can be solved subject to net convection and radiation heat flux boundary conditions.

Interpolation in the radial direction between the solutions leads to a sufficiently smooth representation of the distributions of ceiling surface temperature and convective heat transfer rate. The latter is integrated over the ceiling surface to obtain the net instantaneous rate of convective heat transfer losses from the ceiling jet.

Convective heating and the thermal response of a near-ceiling heat-responsive element, such as a fusible link or thermoplastic drop-out panel, are determined from the local ceiling jet velocity and temperature. Velocity and temperature depend on vertical distance below the ceiling and radial distance from the fire plume axis. If and when its fusion (activation) temperature is reached, the device(s) operated by the link or other heat-responsive element is actuated.

For specific radial distances that are relatively near the plume, the ceiling jet is an inertially dominated flow. Its velocity distribution, depicted in Figure F.2(e), can be estimated from the characteristics of the plume, upstream of ceiling impingement. The ceiling jet temperature distribution, depicted in Figure F.2(f) for a relative “hot” or “cool” ceiling surface, is

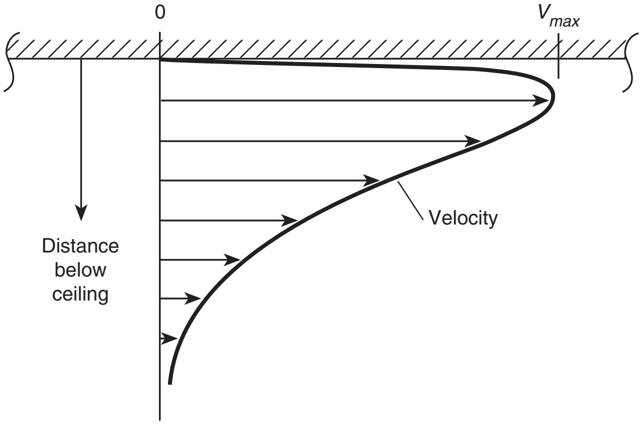

FIGURE F.2(e) Ceiling Jet Velocity.

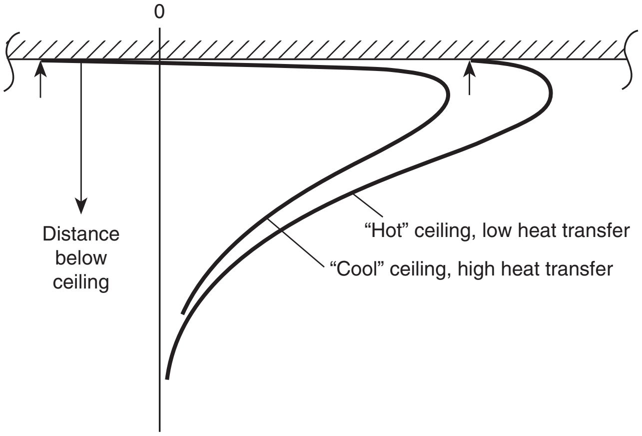

FIGURE F.2(f) Ceiling Jet Temperature.

then estimated from the velocity (which is now known), upper-layer temperature, ceiling-surface temperature, and heat flux distributions.

Annex B provides details of all equations of the LAVENT mathematical fire model and its associated computer program, developed to simulate all the phenomena described thus far. LAVENT can be used to simulate and study parametrically a wide range of relevant fire scenarios involving these phenomena.

Included in B.5.5 is a summary of guidelines, assumptions, and limitations to LAVENT. For example, as specified in that subsection, LAVENT assumes that, at all times during a simulated fire, the overall building space containing the curtained area of fire origin is vented to the outside (e.g., through open doorways). It is assumed, furthermore, that the area of the outside vents is large relative to the area of the open ceiling vents in the curtained area.

Therefore, if the total area of the outside vents is A_{out}, then $(A_{out}/A_V)^2$ is significantly larger than 1 (e.g., $A_{out}/A_V > 2$). If the outside vents are in the bounding walls of the curtained space, not in adjacent spaces, they should be located entirely below the smoke layer boundary. Subsection B.5.5 should be referenced for the details of other guidelines, assumptions, and limitations.

If the actual size of the outside vents is not significantly larger than the vent area, consideration should be given to increasing the vent area to account for the restrictions in inlet air using the following multiplier:

$$M\left[1+\left(\frac{A_v}{A_{V_{out}}}\right)^2 \frac{T_{amb}}{T_U}\right]^{1/2} \quad \textbf{[F.2]}$$

where:

M = multiplier
A_V = total area of open ceiling in curtained space
T_{amb} = outside temperature
A_{Vout} = total area of open vents to outside exclusive of A_V
T_U = upper layer temperature

Annex C is a user guide for the LAVENT computer code. Annex C includes a comprehensive discussion of the inputs and calculated results of a default simulation involving a fire growing in a large pile of wood pallets (t-squared growth to a steady 33 MW) in a 9.1 m high curtained warehouse-type space with multiple fusible-link–actuated vents and near-ceiling–deployed fusible sprinkler links. Vents actuated by alternative means such as thermoplastic “drop-out” panels with equivalent performance characteristics can also be modeled using LAVENT. Inputs to LAVENT include the following.

(1) *Dimensions of the Curtained Area of Fire Origin.* Length, width, and height of the curtained area of fire origin
(2) *Dimensions of the Draft Curtain.* Floor to bottom of the curtain separation distance and length of the curtain (a portion of the perimeter of the curtained space can include floor-to-ceiling walls)
(3) *Properties of the Ceiling.* Thickness, density, thermal conductivity, and heat capacity of the ceiling material
(4) *Characteristics of the Fire.* Elevation of the base of the fire above the floor *(see 9.2.3.6)*; total energy release rate of the fire, at different times during the course of the simulated fire scenario (the computer code uses linear interpolation to approximate between these times); and the

plan area of the fire, or the total energy release rate per unit area of the fire (in cases where the user supplies the latter input, the computer code estimates the changing area of the fire at any moment by using the current total energy release rate)

(5) *Characteristics of the Ceiling Vent–Actuating Fusible Links or Vent-Actuating Smoke Detectors and of the Corresponding Ceiling Vents.* Horizontal distance from the fire, vertical distance below the ceiling surface, RTI, and fuse temperature of the ceiling vent–actuating fusible links; also, the clear open area, A_V, of their associated ceiling vents

(6) *Characteristics of Fusible Sprinkler Links.* Horizontal distance from the fire, vertical distance below the ceiling surface, RTI, and fuse temperature of fusible sprinkler links

LAVENT is written in Fortran 77. The executable code operates on PC-compatible computers.

LAVENT has had some limited experimental validation in experiments with 3.34 m^2 pool fires in a 37 m × 40 m × 14 m high aircraft hangar [Walton and Notarianni, 1993; Notarianni, 1992]. The hangar was equipped with near-ceiling-mounted brass disks of known RTI, which were used to simulate sprinkler links or heat detector elements. The experiments did not involve ceiling vents. Experimental validation of the various mathematical submodel equation sets that comprise the generalized LAVENT simulation is also implicit. This is the case, since the mathematical submodels of LAVENT, presented in Annex B, are based on carefully reproduced correlations of data acquired in appropriate experimental studies of the isolated physical phenomena that, taken together, make up the combined effects of a LAVENT-simulated fire scenario. The experimental basis and validation of the LAVENT submodels can be found in the references listed in Section B.6.

If ceiling vents are actuated by smoke detectors, the guidelines outlined in 9.2.5.4.3 should be followed. LAVENT can be made to simulate this function with a very sensitive fusible link (i.e., a link with a negligibly small RTI) and an appropriate fuse temperature.

As specified in B.4.1, LAVENT always assumes that the flow coefficient, C, for ceiling vents is 0.68; if the user has reason to believe that a different value, C_{user}, is more appropriate for a particular vent (such as the value 0.6 suggested in 9.2.4.2), then the input vent area for that vent should be scaled up proportionately (i.e., A_V, input = $A_V C_{user}/0.68$).

LAVENT calculates the time that the first sprinkler link fuses and the fire environment that develops in the curtained space prior to that time. Because the model does not simulate the interaction of sprinkler sprays and fire environments, any LAVENT simulation results subsequent to sprinkler waterflow should be ignored.

F.3 Objectives of the vent system should be defined and considered. Objectives can include the following:

(1) Provide for fire fighter safety and facilitate post-fire smoke removal by the fire department. The two key issues include activation type (remote or manual removal at roof level by fire fighters), and vent ratio (gross vent area to roof area). Remote activation is a preferred method; however, manual activation at roof level does considerably reduce the time a fire fighter must spend on the roof (versus cutting a hole in the roof) and might be considered acceptable.
(2) Allow extended egress travel distances.
(3) Reduce smoke damage to the contents. Design features such as ganging all vents within a sprinkler zone, and automatically activating all of the vents within one zone following sprinkler activation might achieve objectives 2 and 3; however, additional research is needed to validate this concept.

Chapters 4 through 10 represent the state of technology of vent and draft curtain board design in the absence of sprinklers. A broadly accepted equivalent design basis for using sprinklers, vents, and curtain boards together for hazard control (e.g., property protection, life safety, water usage, obscuration) is currently not available. Designers are strongly cautioned that use of venting with automatic sprinklers is an area of ongoing research to determine its benefit and effect in conjunction with automatic suppression.

This annex section provides design considerations for venting systems in sprinkler-protected areas. These design considerations are based on the research that has been conducted.

Early Research. For occupancies that present a high challenge to sprinkler systems, concern has been raised that the inclusion of automatic roof venting, draft curtains, or both can be detrimental to the performance of automatic sprinklers. Although there is no universally accepted conclusion from fire experience [Miller, 1980], studies on a model scale [Heskestad, 1974] suggested the following:

(1) Venting delays loss of visibility.
(2) Venting results in increased fuel consumption.
(3) Depending on the location of the fire relative to the vents, the water demand necessary to achieve control is either increased or decreased over an unvented condition. With the fire directly under the vent, water demand is decreased. With the fire equidistant from the vents, water demand is increased.

A series of tests was conducted to increase the understanding of the role of automatic roof vents simultaneously employed with automatic sprinklers [Waterman et al., 1982]. The data submitted did not provide a consensus on whether sprinkler control was impaired or enhanced by the presence of automatic (roof) vents for the typical spacing and area.

Large-scale fire tests, conducted at the Factory Mutual Research fire test facility without vents, indicated that certain configurations of draft curtains can have a detrimental effect on the performance of a sprinkler system during a high-challenge fire [Troup, 1994]. Two tests were conducted, one in which a fire was initiated adjacent to a draft curtain, and one near the junction of two draft curtains. Sprinkler performance in these two tests was considered unsatisfactory because an excessive number of sprinklers operated and damage significantly increased in comparison to similar tests conducted without draft curtains.

Other large-scale fire tests were conducted [Hinkley et al., 1992] employing liquid fuels, small vent spacings (minimum of 4.7 m), and vents open at ignition. Hinkley reached the following conclusions:

(1) The prior opening of vents had little effect on the operation of the first sprinkler.
(2) Venting substantially reduced the total number of sprinkler operations.

In an independent analysis of these tests, Gustafsson [1992] noted that sprinklers near the fire source were often delayed or did not operate at all.

Recent Research. The Fire Protection Research Foundation, formerly known as the National Fire Protection Research Foundation, organized large-scale tests to study the interaction of sprinklers, roof vents, and draft curtains [McGrattan et al., 1998], involving heptane spray fires and arrays of cartoned plastic commodity of a standard configuration. The test space was ventilated by a smoke abatement system. The findings were as follows:

(1) In the heptane spray fires, venting had no significant effect on sprinkler operations, unless a fire was ignited directly under a vent, in which case the number of sprinkler operations decreased.
(2) When a draft curtain was installed in the heptane spray fires, the number of operating sprinklers increased.
(3) In five tests with the cartoned plastic commodity, three tests opened 20–23 sprinklers and two tests opened 5–7 sprinklers, which was attributed to variability in the initial fire growth and not to any of the variables under study.
(4) One of these tests with ignition near a draft curtain consumed much more fuel than the other tests, which was attributed to fire spread under the draft curtain.
(5) Effects of venting through roof vents on smoke obscuration could not be determined because of the dominant effect of the building smoke abatement system.
(6) In all experiments in this study where, in some cases, vents were open at the start of the fire, and in those instances where the fire was located directly under a vent, sprinklers performed satisfactorily. Satisfactory sprinkler performance is defined by all of the following criteria:
    (a) Fire did not jump the aisles.
    (b) The number of sprinklers operating did not exceed the design area.
    (c) Fire did not spread to an end of the fuel array.

While the use of automatic venting and draft curtains in sprinklered buildings is still under review, the designer is encouraged to use the available tools and data referenced in this document for solving problems peculiar to a particular type of hazard control [Miller, 1980; Heskestad, 1974; Waterman, 1982; Troup, 1994; Hinkley, et al., 1992; Gustafsson, 1992; McGrattan et al., 1998].

(7) In tests where the vents were opened by fusible link, a number of the vents failed to open, which was attributed to either the cooling effects of the control mode sprinklers on the smoke layer or direct spray cooling of the fusible links.

Design Considerations. As a result of the research, the following guidelines are provided for the design of venting systems in those areas of a building protected with an automatic sprinkler system designed and installed in accordance with NFPA 13 for the specific occupancy hazard.

(1) Draft curtains and open vents of venting systems should not adversely affect sprinklers that are capable of discharging water onto the fire, either in time of operation or in the water discharge pattern.
(2) Vents that are open prior to sprinkler operations in a region surrounding the ignition point, within a radius of 1½ sprinkler spacings, can interfere with the opening of sprinklers capable of delivering water to the fire. The vent system design should consider the following:
    (a) This interference is likely to be a factor if the total vent area is divided among many closely spaced vents, as in the investigation by Hinkley et al. [1992], commented on by Gustafsson [1992].
    (b) If the vent spacing is several times as large as the sprinkler spacing, model fire tests simulating a 1.2 m × 1.2 m vent in a 7.6 m high building [Heskestad, 2008] showed that sprinkler operations were significantly delayed whenever ignition occurred anywhere under the area of an open vent. Otherwise, there was little delay. This delay can be important for systems with early suppression fast response (ESFR) sprinklers.
    (c) Use of high-temperature, heat-responsive actuation mechanisms, compared to the sprinklers, can mitigate the problem of open vents. For example, for 74°C rated ESFR sprinklers, a minimum 180°C activation temperature should be provided for vents. Another approach would be to provide gang operation of the vents at the moment a conservative number of sprinklers are operating.
    (d) The vent system design should consider the effects of the venting system on the ceiling jet.
(3) The location of draft curtains should be determined considering the following:
    (a) Draft curtains can delay or prevent operation and can interfere with the discharge of sprinklers capable of delivering water to the fire. In practice, sprinklers capable of delivering water to the fire can be considered to be those that are within 1½ sprinkler spacings of the ignition point.
    (b) Draft curtains should be located in aisles and should be horizontally separated from combustible contents.
    (c) The layout of the sprinkler protection and the width of the aisle below the draft curtain should be sufficient to prevent the fire from jumping the aisle space. Accordingly, if a draft curtain is positioned midway between two sprinklers, the nearest possible ignition point should be at least ¾ of one sprinkler spacing away from the draft curtain. In other words, there can be no storage of combustible material within ¾ of one sprinkler spacing of a draft curtain. Aisles free of combustible storage, centered under draft curtains, should be at least 1½ sprinkler spacings wide (e.g., a minimum of 15 ft aisle for 10 ft sprinkler spacing in the direction perpendicular to the draft curtain). For situations where such an aisle width is not practical, the aisle space can be reduced to a minimum of 8 ft, when a line of sprinklers is provided on each side of the draft curtain, 4 in. to 12 in. horizontally from the face of the draft curtain. For existing sprinkler installations, these sprinklers near the draft curtain might need to be staggered horizontally with respect to adjacent line of sprinklers, in order to maintain the minimum separation required by NFPA 13 and to prevent sprinkler skipping.
    (d) Where aisles of sufficient width cannot be maintained, full-height partitions can be used in lieu of draft curtains.
(4) The design fire's rate of heat release rate–time history should account for the operation of the sprinkler system.
(5) Determination of the smoke layer temperature should take into account the operation of the control mode sprinkler system. Control mode sprinklers operate when a temperature-rated element fuses in each individual control mode sprinkler head. Since in most fires only a small

number of control mode sprinkler heads close to the seat of the fire operate, it follows that the bulk temperature of the smoke layer and/or the ceiling jet beyond the operating control mode sprinklers cannot be significantly higher than the control mode sprinkler fusible element operating temperature, due to the cooling effect on the smoke of the operating control mode sprinklers. Therefore once the first control mode sprinkler has operated, if calculations show the smoke layer temperature to be above the control mode sprinkler fusible element operating temperature, the smoke layer temperature should be modified to reflect this effect. A possible approach when vents are used would be to set the smoke layer temperature equal to the control mode sprinkler fusible elements operating temperature, this being a reasonably conservative design solution.

(6) The vent flow, smoke movement, and position of the smoke layer boundary should take into account the downdrag effect produced by operation of the sprinkler system.

(7) The effect of control mode sprinkler cooling may limit the number of vents opening if control of the vent is only by fusible link or if drop-out panels are used. If the fusible link or drop-out panel operating temperature is equal to or higher than the control mode sprinkler fusible element operating temperature, then vents outside the outer ring of operating control mode sprinklers are unlikely to open. This could significantly limit the effectiveness of the smoke vent system. Use of ganged vents operated from detectors or a sprinkler flow switch is a way to avoid this situation.

F.4 Recent Literature Review. A recent paper examines the interaction of control mode sprinklers with smoke and heat vents [Beyler and Cooper, 2001]. The paper reviews 13 experimental studies that have some relevance to the claims posed for and against the combined use of control mode sprinklers and smoke/heat vents. These studies are used to evaluate the positive and negative claims that have been made with regard to the combined use of control mode sprinklers and smoke/heat vents. Three of the studies investigate the use of smoke/heat vents alone. Four investigations include control mode sprinklers, but do not include roof vents. Three of these are test series in which perimeter vents were used in the test facility, and the fourth included control mode sprinklers, a partial draft curtain, and no smoke/heat vents. Four test series included control mode sprinklers, smoke/heat vents, and draft curtains, but utilized spray or pool fires that were not subject to extinguishment by the control mode sprinklers. Four test series included control mode sprinklers, smoke/heat vents, and draft curtains, and used Class A fuels that were subject to extinguishment.

The studies of smoke and heat venting used in conjunction with control mode sprinklers do not provide evidence that venting has a negative effect on control mode sprinkler performance.

Experimental studies have shown that venting does limit the spread of products of combustion by releasing them from the building within the curtained compartment of fire origin. This improves visibility for building occupants and fire fighters who need to find the seat of the fire to complete fire extinguishment. Limiting the spread of smoke and heat also reduces smoke and heat damage to the building. In the event that control mode sprinklers do not operate, venting remains a valuable aid to manual control of the fire.

The experimental studies have shown that early vent activation has no detrimental effects on control mode sprinkler performance and have also shown that current design practices are likely to limit the number of vents operated to one and vents may in fact not operate at all in very successful control mode sprinkler operations. Design practices should move to methods that assure early operation of vents, and vent operation should be ganged so that the benefit of roof vents is fully realized. Control mode sprinkler design with vents and draft curtains needs to take full account of draft curtains as obstructions.

Following the publication of the paper by Beyler and Cooper [2001], in a letter to the editor Heskestad [2002] reviewed the conclusions of the authors that: (1) venting clearly does not have a negative effect on sprinkler performance, (2) venting limits spread of combustion products, and (3) venting remains a valuable aid to manual control of the fire in the event the sprinklers do not operate. He argues the view that the first two of these conclusions are performance measures that are not met, or well met, by current technology based on the studies cited by the authors. With respect to the third conclusion, Heskestad refers to the FM Global position that venting, installed as backup to an automatic sprinkler system that is inadequate or impaired, is not cost-effective because it is unlikely a large loss will be averted solely due to the presence of vents.

Annex G Informational References

G.1 Referenced Publications. The documents or portions thereof listed in this annex are referenced within the informational sections of this standard and are not part of the requirements of this document unless also listed in Chapter 2 for other reasons. There are additional lists of references at the ends of Annexes B, C, and D.

NFPA®211

Standard for

Chimneys, Fireplaces, Vents, and Solid Fuel–Burning Appliances

2016 Edition

This edition of NFPA 211, *Standard for Chimneys, Fireplaces, Vents, and Solid Fuel–Burning Appliances*, was prepared by the Committee on Chimneys, Fireplaces, and Venting Systems for Heat-Producing Appliances. It was issued by the Standards Council on November 14, 2015, with an effective date of December 4, 2015, and supersedes all previous editions.

This edition of NFPA 211 was approved as an American National Standard on December 4, 2015.

Origin and Development of NFPA 211

In 1906, the NFPA Committee on Chimneys and Flues presented its first report. In 1914, under the jurisdiction of the then Committee on Field Practice, recommendations on chimneys and flues were prepared as Chapter VII of the *Field Practice Manual*, presented in 1914, and adopted in 1915. In 1926, the Association adopted the Chimney Construction Ordinance of the National Board of Fire Underwriters. In 1944, the Association adopted Article XI of the 1943 edition of the *Building Code of the National Board of Fire Underwriters* to supersede the former chimney ordinance. That action was taken by the Board of Directors in the name of the Association on the recommendation of the Committee on Field Practice.

In 1948, the subject of chimneys and flues was transferred to the Committee on Building Construction. In 1950, the Association adopted Article X of the 1949 *National Building Code of the National Board of Fire Underwriters* to supersede the 1944 standard, on the recommendation of the Committee on Building Construction and action by the Board of Directors.

In 1955, the subject of chimneys and flues was transferred to the newly appointed Committee on Chimneys and Heating Equipment. NFPA 211 was revised in 1957 to make the text consistent with the provisions on the same subject appearing in the *National Building Code of the National Board of Fire Underwriters*. NFPA 211 was revised in 1961 and completely rewritten in 1964. The 1964 edition included requirements for chimney connectors, which were previously covered in NFPA 212, which was withdrawn in 1964. Since 1964, revised editions of the standard were adopted by the Association in 1966, 1968, 1970, 1971, 1972, and 1977. In 1969, new text was added to cover the subject of spark arresters, previously covered in NFPA 213, which was withdrawn in 1969.

In 1980, the scope of NFPA 211 was expanded to include solid-fuel appliances, and in the 1984 edition, major revisions were made to many sections, including important tables and graphs.

The 1988 edition included revisions to wall pass-through systems, including a new Table 5.7, which showed four chimney connector systems. A complete revision to Table 5.5(b) and changes to upgrade test requirements for factory-built chimneys were included.

The 1992 edition included new figures to show fireplace clearance requirements and other construction details, new requirements for combustion air ducts for fireplaces, and a new maintenance chapter that addressed inspection, cleaning, and repair of chimneys, vents, and fireplaces. Definitions for *vent* and *chimney* were revised in the 1996 edition, and the chimney and vent selection charts were moved from Chapter 1 to a new Chapter 2. The new Chapter 2 included new figures to aid in the selection of chimney types.

The 2000 edition included new material that addressed mechanical draft systems, carbon monoxide detection and alarms, and sizing of masonry chimneys. A new chapter, Chapter 11, was added to give detailed direction for the inspection of existing chimneys.

The 2003 edition included a major editorial revision to comply with the *Manual of Style for NFPA Technical Committee Documents*. There were also technical changes in the requirements for the flue cross-sectional area and solid fuel–burning appliance connections to masonry fireplaces.

NFPA and National Fire Protection Association are registered trademarks of the National Fire Protection Association, Quincy, Massachusetts 02169.

The 2006 edition of the standard included new structural and foundation requirements for chimneys and fireplaces, requirements for the effective area of the chimney connector, and requirements for firebox and fireplace construction and sizing, as well as minor editorial changes.

The 2010 edition of the standard included extensive revisions to definitions, deleting those not used in the standard, and clarifying many definitions. Terminology for gas appliances was made consistent with NFPA 54, *National Fuel Gas Code*, by substituting "appliance" for "gas utilization appliance." New minimum requirements for opening for rain caps and spacing of electrical wire from dryer vents were added.

In the 2013 edition, masonry heaters were relocated to a new chapter, and requirements addressing clearance from masonry heaters to combustibles were added. In addition, the 2013 edition included a new prohibition on the use of a duct wrap system to provide enclosure of a factory-built chimney.

The 2016 edition has new provisions for a physical barrier for insulation installed close to a chimney, metal clips to provide structural support, and maximum duct run lengths to harmonize NFPA 211 with other standards. The 2016 edition also sees new requirements for masonry fireplace accessories installation.

This list represents the membership at the time the Committee was balloted on the final text of this edition. Since that time, changes in the membership may have occurred. A key to classifications is found at the back of the document.

NOTE: Membership on a committee shall not in and of itself constitute an endorsement of the Association or any document developed by the committee on which the member serves.

Committee Scope: This Committee shall have primary responsibility for documents on fire safety for the construction, installation, and use of chimneys, fireplaces, vents, venting systems, and solid fuel-burning appliances. It also shall be responsible for documents on clearances of heat-producing appliances from combustible materials and terms relating to chimneys, vents, and heat-producing appliances.

NFPA 211

Standard for

Chimneys, Fireplaces, Vents, and Solid Fuel–Burning Appliances

2016 Edition

IMPORTANT NOTE: This NFPA document is made available for use subject to important notices and legal disclaimers. These notices and disclaimers appear in all publications containing this document and may be found under the heading "Important Notices and Disclaimers Concerning NFPA Documents." They can also be obtained on request from NFPA or viewed at www.nfpa.org/disclaimers.

UPDATES, ALERTS, AND FUTURE EDITIONS: New editions of NFPA codes, standards, recommended practices, and guides (i.e., NFPA Standards) are released on scheduled revision cycles. This edition may be superseded by a later one, or it may be amended outside of its scheduled revision cycle through the issuance of Tentative Interim Amendments (TIAs). An official NFPA Standard at any point in time consists of the current edition of the document, together with any TIAs and Errata in effect. To verify that this document is the current edition or to determine if it has been amended by any TIAs or Errata, please consult the National Fire Codes® Subscription Service or visit the Document Information (DocInfo) pages on the NFPA website at www.nfpa.org/docinfo. In addition to TIAs and Errata, the DocInfo pages also include the option to sign up for Alerts for each document and to be involved in the development of the next edition.

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates that explanatory material on the paragraph can be found in Annex A.

A reference in brackets [ ] following a section or paragraph indicates material that has been extracted from another NFPA document. As an aid to the user, the complete title and edition of the source documents for extracts in mandatory sections of the document are given in Chapter 2 and those for extracts in informational sections are given in Annex B. Extracted text may be edited for consistency and style and may include the revision of internal paragraph references and other references as appropriate. Requests for interpretations or revisions of extracted text shall be sent to the technical committee responsible for the source document.

Information on referenced publications can be found in Chapter 2 and Annex B.

Chapter 1 Administration

1.1 Scope. This standard applies to the design, installation, maintenance, and inspection of all chimneys, fireplaces, venting systems, and solid fuel–burning appliances.

1.2 Purpose.

1.2.1 The primary concern of this standard is the removal of waste gases; the reduction of fire hazards associated with the construction and installation of chimneys, fireplaces, and venting systems for residential, commercial, and industrial appliances; and the installation of solid fuel–burning appliances.

1.2.2 This standard provides minimum construction and installation requirements for chimneys and vents suitable for use with fuel-burning appliances.

1.3 Retroactivity. The provisions of this standard reflect a consensus of what is necessary to provide an acceptable degree of protection from the hazards addressed in this standard at the time the standard was issued.

1.3.1 Unless otherwise specified, the provisions of this standard shall not apply to facilities, equipment, structures, or installations that existed or were approved for construction or installation prior to the effective date of the standard. Where specified, the provisions of this standard shall be retroactive.

1.3.2 In those cases where the authority having jurisdiction determines that the existing situation presents an unacceptable degree of risk, the authority having jurisdiction shall be permitted to apply retroactively any portions of this standard deemed appropriate.

1.3.3 The retroactive requirements of this standard shall be permitted to be modified if their application clearly would be impractical in the judgment of the authority having jurisdiction and only where it is clearly evident that a reasonable degree of safety is provided.

1.4 Equivalency.

1.4.1 General. Nothing in this standard shall prohibit methods of construction, materials, and designs not specifically prescribed in this standard where equivalent alternatives are approved by the authority having jurisdiction.

1.4.2 Approval of Alternatives. Alternative systems, methods, or devices approved as equivalent by the authority having jurisdiction shall be recognized as being in compliance with this standard.

1.4.3 Tests.

1.4.3.1 Whenever the authority having jurisdiction determines that there is insufficient evidence of proof of equivalency with the prescribed requirements of this standard, the authority having jurisdiction shall be authorized to require tests showing proof of equivalency.

1.4.3.2 Tests required by the authority having jurisdiction shall be provided at no expense to the jurisdiction.

1.4.3.3 Tests shall be conducted as specified in this standard or, where test methods are not specified in this standard, they shall be conducted as required by the authority having jurisdiction.

1.4.4 Approval. The authority having jurisdiction shall determine whether the proposed alternative methods of construction, materials, and designs are at least equivalent to the prescribed requirements of this standard.

1.5 Dimensions. Where used to describe building construction components, all minimum dimensions specified in this standard are actual unless otherwise stated. Nominal dimensions shall be permitted to vary from their specified dimensions by no more than ½ in. (12.7 mm).

Chapter 2 Referenced Publications

2.1 General. The documents or portions thereof listed in this chapter are referenced within this standard and shall be considered part of the requirements of this document.

2.2 NFPA Publications. National Fire Protection Association, 1 Batterymarch Park, Quincy, MA 02169-7471.

Chapter 3 Definitions

3.1 General. The definitions contained in this chapter shall apply to the terms used in this standard. Where terms are not defined in this chapter or within another chapter, they shall be defined using their ordinarily accepted meanings within the context in which they are used. *Merriam-Webster's Collegiate Dictionary,* 11th edition, shall be the source for the ordinarily accepted meaning.

3.2 NFPA Official Definitions.

3.2.1* Approved. Acceptable to the authority having jurisdiction.

3.2.2* Authority Having Jurisdiction (AHJ). An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

3.2.3 Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

3.2.4* Listed. Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

3.2.5 Shall. Indicates a mandatory requirement.

3.2.6 Should. Indicates a recommendation or that which is advised but not required.

3.3 General Definitions.

3.3.1* Accessible (for Inspections). Capable of being exposed for inspection, maintenance, or repair without damage to the chimney or building structure or finish, but which may require the removal of doors, panels, or coverings using commonly available tools.

3.3.1.1* ***Readily Accessible (for Inspections).*** Exposed, or capable of being exposed, for operation, inspection, maintenance, or repair without the use of tools to open or remove doors, panels, or coverings.

3.3.2 Accessory. Supplementary part or device added to an appliance to make it more useful, versatile, attractive, and so forth.

3.3.2.1* ***Factory-Built Fireplace Accessories.*** Accessories intended for field installation into or attachment to factory-built fireplaces.

3.3.2.2* ***Masonry Fireplace Accessories.*** Accessories intended for field installation into or attachment to masonry fireplaces.

3.3.3 Air.

3.3.3.1 ***Combustion Air.*** The air necessary to provide for the complete combustion of fuel and usually consisting of primary air, secondary air, and excess air.

3.3.4 Appliance. Any device that utilizes a fuel to produce light, heat, power, refrigeration, or air conditioning.

3.3.4.1 ***Counter Appliance (Gas).*** Appliances such as gas-operated coffee brewers and coffee urns and any appurtenant water-heating equipment, food and dish warmers, hot plates, and griddles.

3.3.4.2* ***Direct Vent Appliance.*** A system consisting of an appliance, combustion air and flue gas connections between the appliance and the outside atmosphere, and a vent cap supplied by the manufacturer, and constructed so that all air for combustion is obtained from the outside atmosphere and all flue gases are discharged to the outside atmosphere.

3.3.4.3 ***Fuel-Burning Appliance.***

3.3.4.3.1 ***Pellet Fuel–Burning Appliance.*** A closed combustion pellet vent or chimney-connected solid pellet fuel–burning appliance incorporating a fuel–feed control mechanism.

3.3.4.3.2 ***Solid Fuel–Burning Appliance.*** A chimney-connected device that burns solid fuel designed for purposes of heating, cooking, or both.

3.3.4.4 ***Heating Appliance.***

3.3.4.4.1 ***Attic-Type Heating Appliance.*** A heating appliance designed specifically for installation in an attic or in a space with low headroom that normally is unoccupied.

3.3.4.4.2 ***Building Heating Appliance.*** See 3.3.4.8, Nonresidential, Low-Heat Appliance.

3.3.4.4.3 ***Residential-Type Heating Appliance.*** Fuel-burning appliances, not including high-pressure steam boilers, that are mainly used in residences but that might be used in other buildings, and that do not produce continuous flue gas temperatures exceeding 1000°F (538°C).

3.3.4.5 ***Heat-Producing Appliance.*** An appliance that produces heat by utilizing electric energy or by burning fuel.

3.3.4.6 ***Nonresidential Appliance, 1400°F.*** A commercial, industrial, or institutional appliance needing a chimney capable of withstanding a continuous flue gas temperature not exceeding 1400°F (760°C).

3.3.4.7 ***Nonresidential, High-Heat Appliance.*** A commercial, industrial, or institutional appliance needing a chimney capable of withstanding a continuous flue gas temperature exceeding 1800°F (982°C).

3.3.4.8 ***Nonresidential, Low-Heat Appliance.*** A commercial, industrial, or institutional appliance needing a chimney capable of withstanding a continuous flue gas temperature not exceeding 1000°F (538°C).

3.3.4.9 ***Nonresidential, Medium-Heat Appliance.*** A commercial, industrial, or institutional appliance needing a chimney capable of withstanding a continuous flue gas temperature not exceeding 1800°F (982°C).

3.3.4.10 ***Vented Appliance.*** An indirect-fired appliance provided with a flue collar to accommodate a venting system for conveying flue gases to the outside atmosphere.

3.3.5 Appliance Casing (or Jacket). An enclosure forming the outside of the appliance.

3.3.6 Appliance Categories. See 3.3.80, Gas Appliance Categories.

3.3.7 Appliance Flue. See 3.3.73.1.

3.3.8 Ash. The solid residue that remains after combustion is complete.

3.3.9 Ash Receptacle Door. A door below the grade level providing access to the ash receptacle.

3.3.10 Attic-Type Heating Appliance. See 3.3.4.4.1.

3.3.11 Automatically Operated Damper. See 3.3.52.1.

3.3.12 Automatic Electric Igniter. A device for fuel burners designed to utilize electric energy for ignition of a fuel–air mixture at the burner.

3.3.13 Barometric Draft Regulator. A device built into a fuel-burning appliance, or made a part of a chimney connector or vent connector, that functions to reduce excessive draft through an appliance to a desired value by admitting ambient air into the appliance chimney, chimney connector, vent, or vent connector.

3.3.14 Boiler. A closed vessel in which water is heated, steam is generated, steam is superheated, or any combination thereof by the application of heat from combustible fuels in a self-contained or attached furnace. [**85,** 2015]

3.3.14.1 ***Combination-Fuel Boiler.*** A single boiler unit designed to burn more than one type of fuel (gas, oil, or solid), either separately or simultaneously, using either separate or common combustion chambers and flues.

3.3.14.2 ***High-Pressure Boiler.*** A boiler for generating steam at gauge pressures in excess of 15 psi (103 kPa), or for heating water to a temperature in excess of 250°F (121°C) or at a gauge pressure in excess of 160 psi (gauge pressure of 1103 kPa).

3.3.14.3 ***Low-Pressure Boiler.*** A boiler for generating steam at gauge pressures not in excess of 15 psi (gauge pressure of 103 kPa) or for furnishing water at a maximum temperature of 250°F (121°C) at a maximum gauge pressure of 160 psi (gauge pressure of 1100 kPa). [**31,** 2016]

3.3.14.4 ***Supplementary Boiler.*** A boiler, designed to burn one type of fuel (gas, oil, or solid), that is intended for supplementing a boiler burning another type of fuel (gas, oil, or solid) by means of a common heat transfer medium.

3.3.15 Bond. Where referring to bricklaying and masonry chimneys, that connection between brick, stone, or other masonry units formed by lapping them upon one another in carrying up the work, thereby forming an inseparable mass.

3.3.16 Breeching. The conduit conveying flue gas from the appliance to the chimney.

3.3.17 Btu. Abbreviation for British thermal unit. The quantity of heat needed to raise the temperature of 1 pound of water 1°F.

3.3.18 Building Heating Appliances. See 3.3.4.8, Nonresidential, Low-Heat Appliance.

3.3.19 Cap.

3.3.19.1 ***Chimney Cap.*** A protective covering or housing for the top of a chimney intended to prevent the entry of rain, snow, animals, and birds, and to prevent downdrafts.

3.3.19.2 ***Vent Cap.*** A protective covering or housing attached to the vent termination, intended for preventing downdrafts and the entry of rain, snow, and animals.

3.3.20 Central Warm-Air, Forced-Air, Attic-Type Furnace. See 3.3.79.1.

3.3.21 Central Warm-Air, Forced-Air, Downflow-Type Furnace. See 3.3.79.2.

3.3.22 Central Warm-Air, Forced-Air, Horizontal-Type Furnace. See 3.3.79.3.

3.3.23 Central Warm-Air, Forced-Air-Type Furnace. See 3.3.79.4.

3.3.24 Central Warm-Air, Forced-Air, Upflow-Type Furnace. See 3.3.79.5.

3.3.25 Central Warm-Air Furnace. See 3.3.79.6.

3.3.26 Central Warm-Air, Gravity-Type Furnace. See 3.3.79.7.

3.3.27 Central Warm-Air, Gravity-Type Furnace with Booster Fan. See 3.3.79.8.

3.3.28 Central Warm-Air, Gravity-Type Furnace with Integral Fan. See 3.3.79.9.

3.3.29 Chimney. A structure containing one or more vertical or nearly vertical passageways for conveying flue gases to the outside atmosphere. *[See also 3.3.142.1, Gas Vent; 3.3.142, Vent; and 3.3.131.2, Venting System (Flue Gases).]*

3.3.29.1 ***Building Heating Appliance Type Chimney.***

3.3.29.1.1 ***Factory-Built, Building Heating Appliance–Type Chimney.*** A heating appliance chimney suitable for continuous use at 1000°F (538°C), composed of listed, factory-built components, designed for open, nonenclosed use at specified minimum clearances to combustibles, and assembled in accordance with the terms of the listing to form the completed chimney.

3.3.29.1.2 ***Factory-Built, Residential-Type and Building Heating Appliance–Type Chimney.*** A chimney suitable for use at 1000°F (538°C), which complies with the 10-minute 1700°F (927°C) temperature test of ANSI/UL 103, *Standard for Factory-Built Chimneys for Residential Type and Building Heating Appliances,* and is composed of listed, factory-built components that might be fully enclosed in combustible, residential-type construction, and that is assembled in accordance with the terms of the listing to form a completed chimney.

3.3.29.1.3* ***Type HT Factory-Built, Residential-Type and/or Building Heating Appliance–Type Chimney.*** A residential type and building heating appliance chimney suitable for use at 1000°F (538°C), which complies with the optional 10-minute 2100°F (1449°C) temperature test of ANSI/UL 103, *Standard for Factory-Built Chimneys for Residential Type and Building Heating Appliances*. Such chimneys are labeled as Type HT and are required for certain solid fuel–fired applications.

3.3.29.2 ***Factory-Built, 1400°F Type Chimney.*** A chimney suitable for continuous use at 1400°F (760°C), composed of listed, factory-built components, intended for open, nonenclosed use at specified minimum clearances to combustibles and for use in noncombustible locations, and assembled in accordance with the terms of the listing to form the completed chimney.

3.3.29.3 ***Factory-Built, Medium-Heat Appliance Type Chimney.*** A chimney used with appliances that produce maximum flue gas temperatures of 1800°F (982°C), composed of listed, factory-built components, suitable for open, nonenclosed use at specified minimum clearances to combustibles, and assembled in accordance with the terms of the listing to form the completed chimney.

3.3.29.4 ***Factory-Built, Positive Pressure Capable Chimney.*** A residential-type or building heating appliance chimney, or both, listed for use in positive internal pressure applications.

3.3.29.5 ***Masonry Chimney.*** A field-constructed chimney of solid masonry units, bricks, stones, listed masonry chimney units, or reinforced Portland cement concrete, lined with suitable chimney flue liners. [**54,** 2015]

3.3.29.6 ***Unlisted Metal (Smokestack) Chimney.*** A manufactured or field-constructed chimney intended only for nonresidential applications having one or more metal walls, or made of metal with a refractory lining, and that is capable of withstanding the flue gas conditions of its use.

3.3.30 Chimney Cap. See 3.3.19.1.

3.3.31 Chimney Connector. See 3.3.48.1.

3.3.32 Chimney Connector-Type Heat Reclaimer. A heat exchanger intended to be installed in a chimney connector between a heating appliance and the chimney to transfer heat from the flue gases through metal to air or water.

3.3.33 Chimney Flue. See 3.3.73.2.

3.3.34 Chimney Flue Base (Base of Flue). The lowest point of a flue within a chimney.

3.3.35 Chute-Fed Incinerator (Class IIA). See 3.3.91.1.

3.3.36 Circulating Room Heater. See 3.3.88.2.1.

3.3.37 Cleanout Opening. An opening or hole in a chimney, usually located near its base, designed to allow access to the flue for purposes of removing ash, creosote, soot, and other extraneous matter that becomes trapped.

3.3.38 Clearance. The distance between a heat-producing appliance, chimney, chimney connector, vent, vent connector, or plenum and other surfaces.

3.3.39 Clothes Dryer. A device used to dry wet laundry by means of heat derived from the combustion of fuel or from electric heating elements.

3.3.39.1 ***Type 1 Clothes Dryer.*** A factory-built, mass-produced dryer, primarily used in a family living environment. It might or might not be coin-operated for public use and usually is the smallest unit both physically and in function.

3.3.39.2 ***Type 2 Clothes Dryer.*** A factory-built, mass-produced dryer used in a commercial business. It might or might not be operated by the public or a hired attendant. It might or might not be coin-operated and is not designed for use in an individual family living environment. It can be small, medium, or large in size.

3.3.40 Combination-Fuel Boiler. See 3.3.14.1.

3.3.41 Combination-Fuel Furnace. See 3.3.79.10.

3.3.42 Combination Room Heater/Fireplace Stove. See 3.3.70.1.

3.3.43 Combustible Material. See 3.3.100.1.

3.3.44 Combustion. A chemical process of oxidation that occurs at a rate fast enough to produce heat and usually light in the form of either a glow or flame. [**5000,** 2015]

3.3.45 Combustion Air. See 3.3.3.1.

3.3.46 Combustion Products. Constituents resulting from the combustion of a fuel with the oxygen of the air, including the inert but excluding excess air. [**54,** 2015]

3.3.47 Commercial-Industrial-Type Incinerator (Classes III, IV, V, VI, and VII). See 3.3.91.2.

3.3.48 Connector.

3.3.48.1 ***Chimney Connector.*** The pipe that connects a fuel-burning appliance to a chimney.

3.3.48.2 ***Vent Connector.*** The pipe that connects a fuel-burning appliance to a gas vent or Type L vent.

3.3.49 Corbel. Units of masonry projecting from or projecting upward and outward from the face of a wall or chimney in courses to form a support or ledge for a beam, rafter, or other member.

3.3.50 Counter Appliance (Gas). See 3.3.4.1.

3.3.51* Crown. A sloped covering for the top of a masonry chimney that is designed to shed water away from the flue liner and the chimney and to allow expansion and movement of the flue liner.

3.3.52 Damper. A valve or plate for controlling draft or the flow of gases, including air.

3.3.52.1 ***Automatically Operated Damper.*** A damper operated by an automatic control.

3.3.52.2 ***Flue Gas Damper.*** A damper located on the downstream side of the combustion chamber of a fuel-burning appliance, usually in a flue passage of the appliance or in the chimney or vent connector.

3.3.52.3 ***Manually Operated Damper.*** An adjustable damper manually set and locked in the desired position.

3.3.53 Decorative Shroud. A partial enclosure for aesthetic purposes that is installed at the termination of a venting system that surrounds or conceals the chimney or vent cap.

3.3.54 Dilution Flue. See 3.3.73.3.

3.3.55 Direct Vent Appliance. See 3.3.4.2.

3.3.56 Draft. A pressure difference that causes gases or air to flow through a chimney, vent, flue, or appliance. [**54,** 2015]

3.3.56.1* ***Mechanical Draft.*** Draft produced by a fan or an air or steam jet.

3.3.56.2 ***Natural Draft.*** Draft produced by the difference in the weight of a column of flue gases within a chimney or vent system and a corresponding column of air of equal dimension outside the chimney or venting system. [**31,**2016]

3.3.57 Draft Hood. A nonadjustable device built into an appliance, or made a part of the vent connector from an appliance, that is designed to (1) provide for the ready escape of the flue gases from the appliance in the event of no draft, backdraft, or stoppage beyond the draft hood, (2) prevent a backdraft from entering the appliance, and (3) neutralize the effect of stack action of the chimney or gas vent upon the operation of the appliance. [**54,** 2015]

3.3.58 Duct Furnace. See 3.3.79.11.

3.3.59 Engineered Venting or Chimney System. See 3.3.131.1.

3.3.60 Factory-Built, 1400°F Type Chimney. See 3.3.29.2.

3.3.61 Factory-Built, Building Heating Appliance Type Chimney. See 3.3.29.1.1.

3.3.62 Factory-Built Fireplace. See 3.3.68.1.

3.3.63 Factory-Built, Medium-Heat Appliance Type Chimney. See 3.3.29.3.

3.3.64 Factory-Built, Positive Pressure Capable Chimney. See 3.3.29.4.

3.3.65 Factory-Built, Residential Type and Building Heating Appliance Type Chimney. See 3.3.29.1.2.

3.3.66 Fan. A blower or exhauster assembly comprising blades or runners and housings or casings.

3.3.67 Fan-Type Floor Furnace. See 3.3.79.12.1.

3.3.68 Fireplace. A hearth, fire chamber, or similarly prepared area and a chimney.

3.3.68.1 ***Factory-Built Fireplace.*** A fireplace composed of listed, factory-built components assembled in accordance with the terms of the listing.

3.3.68.2 ***Masonry Fireplace.*** A hearth and fire chamber of solid masonry units, such as bricks, stones, listed masonry units, or reinforced concrete, provided with a suitable chimney.

3.3.69 Fireplace Insert. A factory-built, field-installed product consisting of a firebox assembly designed to be installed within or partially within the fire chamber of a fireplace that uses the fireplace flue to vent the products of combustion.

3.3.70 Fireplace Stove. A freestanding, chimney-connected, solid fuel–burning appliance that is designed to be operated with the fire chamber either open or closed.

3.3.70.1 ***Combination Room Heater/Fireplace Stove.*** A chimney-connected, solid fuel–burning room heater that is designed to be operated with the fire chamber either open or closed.

3.3.71 Floor Furnace. See 3.3.79.12.

3.3.72 Floor Protector. A noncombustible surfacing applied to the floor area underneath and extending in front, to the sides, and to the rear of a heat-producing appliance.

3.3.73 Flue. The general term for a passage through which gases are conveyed from the combustion chamber to the outer air.

3.3.73.1 ***Appliance Flue.*** The flue passage within an appliance.

3.3.73.2 ***Chimney Flue.*** The passage in a chimney for conveying the flue gases to the outside atmosphere.

3.3.73.3 ***Dilution Flue.*** A passage designed to effect the dilution of flue gases with air before discharge from an appliance.

3.3.74 Flue Collar. That portion of an appliance designed for attachment of a chimney or vent connector or a draft hood.

3.3.75 Flue-Fed Incinerator (Class II). See 3.3.91.3.

3.3.76 Flue Gas Damper. See 3.3.52.2.

3.3.77 Flue Gases. See 3.3.82.1.

3.3.78 Fuel. A material used to produce heat or power by burning.

3.3.78.1 ***Pellet Fuel.*** A solid processed fuel of specified size and composition capable of being fed to the appliance combustion system at a controlled rate.

3.3.78.2 ***Solid Fuel.*** Wood, coal, and other similar organic materials and any combination of them.

3.3.79 Furnace.

3.3.79.1 ***Central Warm-Air, Forced-Air, Attic-Type Furnace.*** A forced-air-type furnace designed specifically for installation in an attic or in a space with low headroom that is normally occupied.

3.3.79.2 ***Central Warm-Air, Forced-Air, Downflow-Type Furnace.*** A forced-air-type furnace designed with airflow essentially in a vertical path, discharging air at or near the bottom of the furnace.

3.3.79.3 ***Central Warm-Air, Forced-Air, Horizontal-Type Furnace.*** A forced-air-type furnace designed with airflow through the furnace, essentially in a horizontal path.

3.3.79.4 ***Central Warm-Air, Forced-Air-Type Furnace.*** A central furnace equipped with a blower that provides the primary means for the circulation of air.

3.3.79.5 ***Central Warm-Air, Forced-Air, Upflow-Type Furnace.*** A forced-air-type furnace designed with airflow essentially in a vertical path, discharging air at or near the top of the furnace.

3.3.79.6 ***Central Warm-Air Furnace.*** A self-contained indirect-fired or electrically heated appliance designed to supply heated air through ducts to spaces remote from or adjacent to the appliance location.

3.3.79.7 ***Central Warm-Air, Gravity-Type Furnace.*** A central furnace depending primarily on circulation of air by gravity.

3.3.79.8 ***Central Warm-Air, Gravity-Type Furnace with Booster Fan.*** A central furnace equipped with a booster fan that does not materially restrict free circulation of air by gravity flow when such a fan is not in operation.

3.3.79.9 ***Central Warm-Air, Gravity-Type Furnace with Integral Fan.*** A central furnace equipped with a fan as an integral part of its construction and operable on gravity systems only. The fan is used only to overcome the internal resistance to airflow.

3.3.79.10 ***Combination-Fuel Furnace.*** A single furnace unit designed to burn more than one type of fuel (gas, oil, or solid), either separately or simultaneously, using either separate or common combustion chambers and flues.

3.3.79.11 ***Duct Furnace.*** A central furnace designed for installation in a duct of an air distribution system to supply warm air for heating and that depends on a blower not furnished as part of the furnace for air circulation.

3.3.79.12 ***Floor Furnace.*** A self-contained indirect-fired or electrically heated furnace designed to be suspended from the floor of the space to be heated. A fuel-burning floor furnace is designed to take air for combustion from outside the space being heated and is provided with means for observing the flame and lighting the appliance from such space.

3.3.79.12.1 ***Fan-Type Floor Furnace.*** A floor furnace equipped with a blower that provides the primary means for circulation of air.

3.3.79.12.2 ***Gravity-Type Floor Furnace.*** A floor furnace depending primarily on circulation of air by gravity. This classification also includes floor furnaces equipped with booster-type fans that do not materially restrict free circulation of air by gravity flow when such fans are not in operation.

3.3.79.13 ***Supplementary Furnace.*** A furnace designed to burn one type of fuel (gas, oil, or solid) that is intended for supplementing a central warm-air furnace burning another type of fuel (gas, oil, or solid) by means of a common warm-air supply plenum.

3.3.80* Gas Appliance Categories. Vented gas appliances are classified for venting purposes into four categories as follows: (1) Category I — An appliance that operates with a non-positive vent static pressure and with a vent gas temperature that avoids excessive condensate production in the vent; (2) Category II — An appliance that operates with a non-positive vent static pressure and with a vent gas temperature that may cause excessive condensate production in the vent; (3) Category III — An appliance that operates with a positive vent static pressure and with a vent gas temperature that avoids excessive condensate production in the vent; (4) Category IV — An appliance that operates with a positive vent static pressure and with a vent gas temperature that may cause excessive condensate production in the vent.

3.3.81 Gas Vent. See 3.3.142.1.

3.3.82 Gases.

3.3.82.1 ***Flue Gases.*** Combustion products from fuel-burning appliances along with excess air.

3.3.82.2 ***Vent Gases.*** Products of combustion from fuel-burning appliances along with excess air, plus any dilution air in the venting system above a draft hood or draft regulator.

3.3.83 Gravity-Type Floor Furnace. See 3.3.79.12.2.

3.3.84 Header. Where referring to chimneys, a beam set at right angles to floor or roof joists to provide support and framing around the opening.

3.3.85 Hearth. The floor area within the fire chamber of a fireplace or a fireplace stove.

3.3.86 Hearth Extension. The noncombustible surfacing applied to the floor area extending in front of and at the sides of the hearth opening of a fireplace or a fireplace stove; also where applied to the floor area beneath a fireplace stove or beneath an elevated overhanging fireplace hearth.

3.3.87 Heat Exchanger. A chamber in which heat resulting directly from the combustion of fuel, or heat from a medium such as air, water, or steam, is transferred through the walls of the chamber to air passing through the exchanger; or a chamber in which heat from electric resistors is transferred to the air.

3.3.88 Heater.

3.3.88.1 ***Masonry Heater.*** A vented heating system of predominantly masonry construction having a mass of at least 1760 lb (800 kg) excluding the chimney and masonry heater base.

3.3.88.2 ***Room Heater.*** A heating appliance intended for installation in the space being heated and not intended for duct connection.

3.3.88.2.1 ***Circulating Room Heater.*** A room heater with an outer jacket surrounding the heat exchanger, arranged with openings at top and bottom so that air circulates between the heat exchanger and the outer jacket. Room heaters that have openings in an outer jacket to allow some direct radiation from the heat exchanger are classified as a radiant type.

3.3.88.2.2 ***Radiant Room Heater.*** A room heater designed to transfer heat primarily by direct radiation.

3.3.88.2.3 ***Solid Fuel Room Heater.*** A chimney-connected, solid fuel–burning room heater that is designed to be operated with the fire chamber closed.

3.3.88.3 ***Unit Heater.*** A self-contained heating appliance that is intended for the heating of the space in which it is installed. A unit heater can be an indirect-fired fuel-burning appliance or might utilize steam, hot water, or electricity.

3.3.88.4 ***Water Heater.*** A fuel-burning appliance for heating water to a temperature not more than 200°F (93°C).

3.3.89 Heat-Producing Appliance. See 3.3.4.5.

3.3.90 High-Pressure Boiler. See 3.3.14.2.

3.3.91 Incinerator. An appliance or combustion chamber for the reduction, by burning, of rubbish, garbage, and other wastes.

3.3.91.1 ***Chute-Fed Incinerator (Class IIA).*** An incinerator designed specifically to be fed refuse from one or more floors above the incinerator directly into the incinerator by a separate chute constructed with a positive means to avoid penetration by smoke or fumes and connected directly over the primary combustion chamber. The incinerator is built with a primary and a secondary combustion chamber and a settling chamber. It can include a flue gas washer or scrubber. A separate chimney serves to convey the combustion gases to the outdoors. This class of incinerator is suitable for Type 1 and Type 2 wastes. It generally is used in residential and institutional buildings, including apartments, clubs, dormitories, churches, schools, and other occupancies where Type 1 and Type 2 wastes are to be incinerated.

3.3.91.2 ***Commercial-Industrial-Type Incinerator (Classes III, IV, V, VI, and VII).*** An incinerator having a charging capacity in excess of 5 ft^3 (0.14 m^3) and suitable for a variety of wastes as follows: (1) Class III — Waste Type 0, Type 1, or Type 2; (2) Class IV — Waste Type 3; (3) Class V— Waste Types 0–4 (municipal incinerators); (4) Class VI — Waste Type 4; (5) Class VII — Waste Types 5 and 6.

3.3.91.3 ***Flue-Fed Incinerator (Class II).*** An incinerator served by a single chimney flue that serves also as the charging chute, where refuse is fed directly to the incinerator through this chimney flue from one or more floors above the incinerator. This class of incinerator is suitable for Type 1 and Type 2 waste materials and garbage incidental to residential occupancy in single-family and multifamily buildings. This class of incinerator is generally used in residential and institutional buildings, including apartments, clubs, dormitories, churches, schools, and other occupancies where Type 1 and Type 2 wastes are to be incinerated.

3.3.91.4 ***Residential-Type Incinerator.*** An incinerator for the burning of ordinary combustible waste material and garbage (Type 2 waste) incidental to residential occupancy and having a firebox or charging compartment not greater than 5 ft^3 (0.14 m^3) in capacity. Residential-type incinerators can be self-contained, factory-built units that do not necessitate field construction, or can be of a built-in type designed to be encased in masonry or installed in a masonry wall or chimney.

3.3.92 Low-Pressure Boiler. See 3.3.14.3.

3.3.93 Mantel. A shelf or facing ornament above a fireplace opening.

3.3.94 Manually Operated Damper. See 3.3.52.3.

3.3.95 Manufacturer. The person or persons, company, firm, corporation, partnership, or other organization responsible for turning raw materials or components into a finished product.

3.3.96 Masonry Chimney. See 3.3.29.5.

3.3.97 Masonry Fireplace. See 3.3.68.2.

3.3.98 Masonry Fireplace Lintel. The horizontal, noncombustible member, usually of masonry or steel, spanning the opening of a masonry fireplace to support the load above.

3.3.99 Masonry Heater. See 3.3.88.1.

3.3.100 Material.

3.3.100.1 ***Combustible Material.*** Material made of or surfaced with wood, compressed paper, plant fibers, plastics, or other material that can ignite and burn, whether flame-proofed or not, or whether plastered or unplastered.

3.3.100.2 ***Noncombustible Material.*** A material that, in the form in which it is used and under the conditions anticipated, will not ignite, burn, support combustion, or release flammable vapors, when subjected to fire or heat; materials that are reported as passing ASTM E136, *Standard Test Method for Behavior of Materials in a Vertical Tube Furnace at 750°C*, shall be considered noncombustible materials.

3.3.101 Mechanical Draft. See 3.3.56.1.

3.3.102 Natural Draft. See 3.3.56.2.

3.3.103 Noncombustible Material. See 3.3.100.2.

3.3.104 Nonresidential Appliance, 1400°F. See 3.3.4.6.

3.3.105 Nonresidential, High-Heat Appliance. See 3.3.4.7.

3.3.106 Nonresidential, Low-Heat Appliance. See 3.3.4.8.

3.3.107 Nonresidential, Medium-Heat Appliance. See 3.3.4.9.

3.3.108 Pellet Fuel. See 3.3.78.1.

3.3.109 Pellet Fuel–Burning Appliance. See 3.3.4.3.1.

3.3.110 Pellet Vent. See 3.3.142.2.

3.3.111 Qualified Agency. Any individual, firm, corporation, or company that, either in person or through a representative, is engaged in and is responsible for the connection, venting, installation, inspection, repair, or servicing of heat-producing appliances and who is experienced in such work, is familiar with all precautions required, and has complied with all the requirements of the AHJ.

3.3.112 Radiant Room Heater. See 3.3.88.2.2.

3.3.113 Readily Accessible. See 3.3.1.1.

3.3.114 Residential-Type Heating Appliance. See 3.3.4.4.3.

3.3.115 Residential-Type Incinerator. See 3.3.91.4.

3.3.116 Roof Jack. A factory-built assembly for conveying flue gases through a roof and that includes a flue gas passageway, an insulating means, flashing, and a cap.

3.3.117 Room Heater. See 3.3.88.2.

3.3.118 Smoke Chamber. The transitional area from the damper opening to the beginning of the flue liner in a fireplace system.

3.3.119 Smoke Test. A procedure for ascertaining the tightness of a chimney and for detecting any cracks in a masonry chimney flue or deterioration or breaks in the integrity of a metal chimney flue, and that involves igniting a smoke bomb or building a smoky fire in a fireplace or solid fuel–burning appliance, covering the chimney termination, and checking for smoke escapage through the chimney walls.

3.3.120 Solid Fuel. See 3.3.78.2.

3.3.121 Solid Fuel–Burning Appliance. See 3.3.4.3.2.

3.3.122 Solid Fuel Room Heater. See 3.3.88.2.3.

3.3.123 Solid Masonry Construction. A bonded assembly of stones or solid masonry units.

3.3.124 Solid Masonry Unit. A masonry unit whose net cross-sectional area in every plane parallel to the bearing surface is 75 percent or more of its gross cross-sectional area measured in the same plane.

3.3.125 Spark Arresters. Screening material or a screening device attached to a chimney termination to prevent the passage of sparks and brands to the outside atmosphere.

3.3.126 Special Gas Vent. See 3.3.142.1.1.

3.3.127 Splay. See 3.3.150, Wash.

3.3.128 Steel Fireplace Unit. A unit consisting of a steel firebox and an air chamber adjacent to the sides and rear of the firebox, used to construct a masonry fireplace. The unit usually has ducts to circulate air to and heated air from the air chamber to the living space.

3.3.129 Supplementary Boiler. See 3.3.14.4.

3.3.130 Supplementary Furnace. See 3.3.79.13.

3.3.131 System.

3.3.131.1* ***Engineered Venting or Chimney System.*** A system that has been sized and configured in accordance with approved engineering methods.

3.3.131.2 ***Venting System (Flue Gases).*** A continuous, open passageway from the flue collar or draft hood of a fuel-burning appliance to the outside atmosphere for the purpose of removing flue gases.

3.3.132 Thimble. A fixed or removable ring, tube, or lining usually located in the hole where the chimney connector or vent connector passes through a wall or enters a chimney or vent.

3.3.133 Trimmer. Where referring to chimneys, the longer floor or roof framing member around a rectangular opening into which the end of a header is joined.

3.3.134 Type 1 Clothes Dryer. See 3.3.39.1.

3.3.135 Type 2 Clothes Dryer. See 3.3.39.2.

3.3.136 Type B Gas Vent. See 3.3.142.1.2.

3.3.137 Type BW Gas Vent. See 3.3.142.1.3.

3.3.138 Type HT Factory-Built, Residential-Type and/or Building Heating Appliance Type Chimney. See 3.3.29.1.3.

3.3.139 Type L Vent. See 3.3.142.3.

3.3.140 Unit Heater. See 3.3.88.3.

3.3.141 Unlisted Metal (Smokestack) Chimney. See 3.3.29.6.

3.3.142* Vent. A flue gas–conveying system intended for use only with certain gas-, liquid-, or pellet fuel–fired appliances that do not produce flue gas outlet temperatures higher than a value specified in the listing vent standards.

3.3.142.1 ***Gas Vent.*** A passageway composed of listed factory-built components assembled in accordance with the manufacturer's installation instructions for conveying vent gases from appliances or their vent connectors to the outdoors. [**54,** 2015]

3.3.142.1.1 ***Special Gas Vent.*** A gas vent for venting listed Category II, III, and IV gas appliances.

3.3.142.1.2 ***Type B Gas Vent.*** A vent for venting listed gas appliances with draft hoods and other Category I appliances listed for use with Type B gas vents. [**54,** 2015]

3.3.142.1.3 ***Type BW Gas Vent.*** A vertical or nearly vertical gas vent for venting listed gas-fired vented wall furnaces.

3.3.142.2 ***Pellet Vent.*** A venting system composed of listed, factory-built components assembled in accordance with the manufacturer's instructions for conveying flue gases from a listed pellet fuel–burning appliance to the outside atmosphere.

3.3.142.3 ***Type L Vent.*** A vertical or nearly vertical vent composed of listed factory-built components assembled in accordance with the terms of a listing for conveying flue gases from oil and gas appliances or their vent connectors to the outside atmosphere.

3.3.143 Vent Cap. See 3.3.19.2.

3.3.144 Vent Connector. See 3.3.48.2.

3.3.145 Vent Gases. See 3.3.82.2.

3.3.146 Vented Appliance. See 3.3.4.10.

3.3.147 Venting. Removal of combustion products as well as noxious or toxic fumes to the outside atmosphere.

3.3.148 Venting System (Flue Gases). See 3.3.131.2.

3.3.149 Wall Protector (Shield). Noncombustible surfacing applied to a wall area for the purpose of reducing the clearance between the wall and a heat-producing appliance.

3.3.150 Wash. A slight slope or beveled edge on the top surface of a chimney designed to shed water away from the flue liner; also called a *splay*.

3.3.151 Water Heater. See 3.3.88.4.

3.3.152 Wythe. Where referring to masonry chimneys, a course, a thickness, or a continuous vertical section of masonry separating flues in a chimney.

Chapter 4 General Requirements

4.1* Sizing and Draft.

4.1.1 Minimum Performance. A chimney or vent shall be so designed and constructed to develop a flow sufficient to remove completely all flue or vent gases to the outside atmosphere.

4.1.1.1 Chimneys or vents shall be evaluated to ensure proper performance with respect to draft, creosote buildup, and condensation.

4.1.1.2 The venting system shall satisfy the draft requirements of the connected appliance(s) in accordance with the manufacturers' instructions or approved methods.

4.1.2 Mechanical Draft Systems. A listed mechanical draft system of either forced or induced draft design shall be permitted to be used to increase draft or capacity.

4.1.2.1 Where a mechanical draft system is installed, provision shall be made to prevent the flow of fuel to an automatically fired appliance(s) when that system is not operating.

4.1.2.2 The operation of a mechanical draft system shall not adversely affect the performance or safety of, or cause spillage of combustion products from, other combustion equipment operating within the same building.

4.1.2.3 Proper performance and safety of other combustion equipment shall be verified by testing prior to the mechanical draft system being put into service.

4.1.2.4 Such testing shall include operation of the mechanical draft system together with other exhaust equipment likely to operate simultaneously.

4.1.2.5 Mechanical draft systems of either forced or induced draft serving manually fired appliances shall be one of the following:

(1) A mechanical draft system that is an integral part of a listed appliance
(2) A solid-fuel cooking appliance as addressed in NFPA 96
(3)* An engineered mechanical draft system that includes the following provisions:
    (a) Line voltage devices, when installed, shall be provided with a battery backup system, and the following detection and warning devices shall be installed:
        i. A device that produces an audible and visible warning upon failure of the mechanical draft system. The device shall be activated by loss of electrical power supply or by operational failure of the mechanical draft system at any time while the mechanical draft system is switched on.
        ii. A smoke detector and alarm installed and maintained in accordance with *NFPA 72*. The detector shall be installed in the same room as the appliance served by the mechanical draft system.
        iii. A listed carbon monoxide warning device installed in accordance with the manufacturer's instructions.
    (b) The mechanical draft system shall be listed in accordance with UL 378, *Standard for Draft Equipment*, for use with the type of appliance and range of chimney service appropriate for the application. The mechanical draft system shall not cause or permit blockage of the flue or electrical hazard after exposure to a chimney fire or over-fire conditions. The mechanical draft system shall be installed in accordance with the terms of the listing and the manufacturer's instructions.
    (c) The mechanical draft system shall be sized to maintain draft within the range specified by the appliance manufacturer.

4.1.3 Natural Draft Sizing. Chimneys serving incinerators or other process equipment where the combustion process cannot be stopped completely by fuel shutoff alone shall be sized for natural draft conditions.

4.1.3.1 Where air pollution control devices or other devices in the chimney system require a mechanical draft system, the chimney system shall be so arranged that, upon a power failure, the natural draft chimney alone can satisfactorily remove the products of combustion until the combustible material is completely consumed.

4.1.4 Forced/Induced Draft Systems. Forced draft systems and all portions of induced draft systems under positive pressure during operation shall be designed and installed to be gastight or to prevent the leakage of combustion products into a building.

4.1.5 Natural Draft Vent Connectors. Vent connectors serving appliances vented by natural draft shall not be connected into any portion of mechanical draft systems operating under positive pressure.

4.2 Termination (Height). Chimneys and vents shall terminate above the roof level in accordance with the requirements of this standard and as illustrated in Figure 4.2(a) and Figure 4.2(b).

4.2.1 Masonry chimneys shall extend above the highest point at which they pass through the roof of a building by at least the distance specified in Table 7.2, Column VI, and shall also extend at least the specified distance above any portion of any structure within the specified proximity (measured horizontally from the vertical chimney line) in Table 7.2, Column VII.

4.2.2 Natural draft chimneys and vents shall not terminate at an elevation less than 5 ft (1.53 m) above the flue collar or the highest connected draft hood outlet.

Exception: As provided in Section 10.7.

4.3 Enclosure.

4.3.1 General. Interior residential chimneys shall be enclosed where they extend through closets, storage areas, or habitable spaces where the surface of the chimney could come into contact with persons or combustible materials.

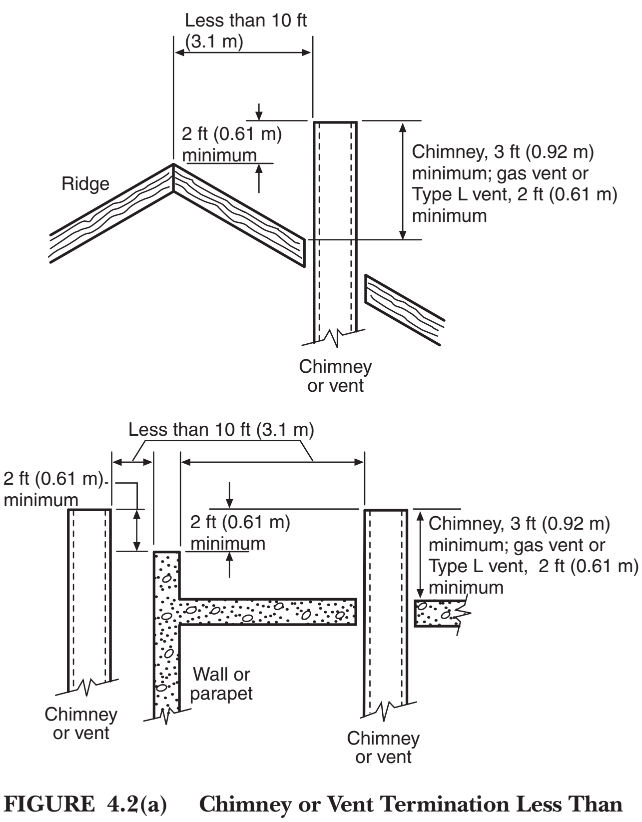

FIGURE 4.2(a) Chimney or Vent Termination Less Than 10 ft (3.1 m) from Ridge, Wall, or Parapet.

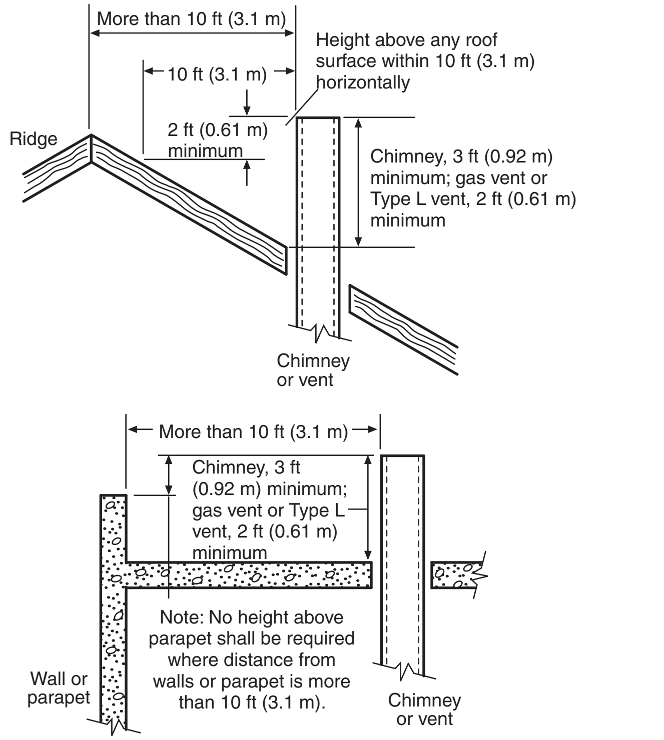

FIGURE 4.2(b) Chimney or Vent Termination More Than 10 ft (3.1 m) from Ridge, Wall, or Parapet.

4.3.2 Clearance. The space between the chimney and the enclosure shall be at least the minimum air space clearance specified in this standard *(see Table 7.2)* or the clearance specified in the manufacturer's instructions for listed chimneys.

4.4 Venting Systems in Ducts.

4.4.1 Circulating Air Ducts and Plenums. No portion of a venting system shall extend into or pass through a dedicated circulating air duct or plenum.

4.4.2 Above-Ceiling Spaces. Where a venting system passes through a space above a ceiling used as a return air plenum, it shall be installed according to one of the following methods:

(1) With joints within the above-ceiling return air plenum sealed airtight in a manner approved by the manufacturer of the venting system
(2) As a listed positive-pressure venting system
(3) Non-airtight venting system installed with no joints or fittings located within the above-ceiling return air plenum

4.5 Flue Lining.

4.5.1 Resistance Equivalency. Castable or plastic refractories used to line chimneys or connectors shall be the equivalent in resistance to heat and erosion by flue gases to that of the fireclay brick.

4.5.2 Lining Support. Lining made of castable or plastic refractories shall be secured to the supporting walls by anchors made of corrosion-resistant steel capable of supporting the refractory load at 1500°F (816°C).

4.5.3 Space Surrounding Liner or Vent. The remaining space surrounding a chimney liner, gas vent, special gas vent, or plastic piping installed within a chimney flue shall not be used to vent another appliance.

4.6 Caps and Spark Arresters for Chimneys and Vents.

4.6.1 Design. Chimney or vent caps, where required for the termination of chimneys or vents, shall be designed to prevent the entry of rain, snow, and birds and other animals.

4.6.2 Rain Cap Height. The minimum distance from the underside of an unlisted rain cap to the top of covered flues shall be the lesser dimension of the width or depth of the covered flue. Where more than one flue is covered, the lesser dimension of the highest flue shall be used.

4.6.3 Screening. Screening material attached to chimney or vent caps to prevent the entry of animals and insects shall not adversely affect the chimney or vent draft.

4.6.4 Spark Arresters.

4.6.4.1 Spark arresters, where required by the AHJ for chimneys attached to solid fuel–burning equipment, shall meet the following requirements:

(1) The net free area of the arrester shall be not less than three times the net free area of the outlet of the chimney flue it serves.
(2) The arrester screen shall have heat and corrosion resistance equivalent to 19 gauge [0.041 in. (1.04 mm)] galvanized steel or 24 gauge [0.024 in. (0.61 mm)] stainless steel.
(3) Openings shall not allow the passage of spheres having a diameter larger than ½ in. (12.7 mm) or block the passage of spheres having a diameter of less than ⅜ in. (9.5 mm).
(4) The spark screen shall be accessible for cleaning, and the screen or chimney cap shall be removable to allow cleaning of the chimney flue.

4.6.4.2 Where part of a listed chimney termination system, spark arresters shall be constructed and installed in accordance with the listing.

Chapter 5 Selection of Chimney and Vent Types

5.1 Chimney Types.

5.1.1 Selection. Chimney selection shall be limited to three basic chimney types: factory-built, masonry, and unlisted metal *[see Figure 5.1.1(a) through Figure 5.1.1(c)]*.

5.1.2 Application. Each basic chimney type is defined in Chapter 3, and the application of each is determined by Table 5.2.2.1, with specific construction or installation requirements in Chapters 6, 7, and 8.

5.2 Chimney or Vent Selection.

5.2.1 General. The selection of a chimney or vent shall be based on the following:

(1) Type of appliance connected thereto
(2) Fuel used by the appliance
(3) Temperature of the flue gases at the appliance outlet
(4) Pressure within the chimney or vent

5.2.2 Chimneys.

5.2.2.1 The chimney type shall be selected according to Table 5.2.2.1.

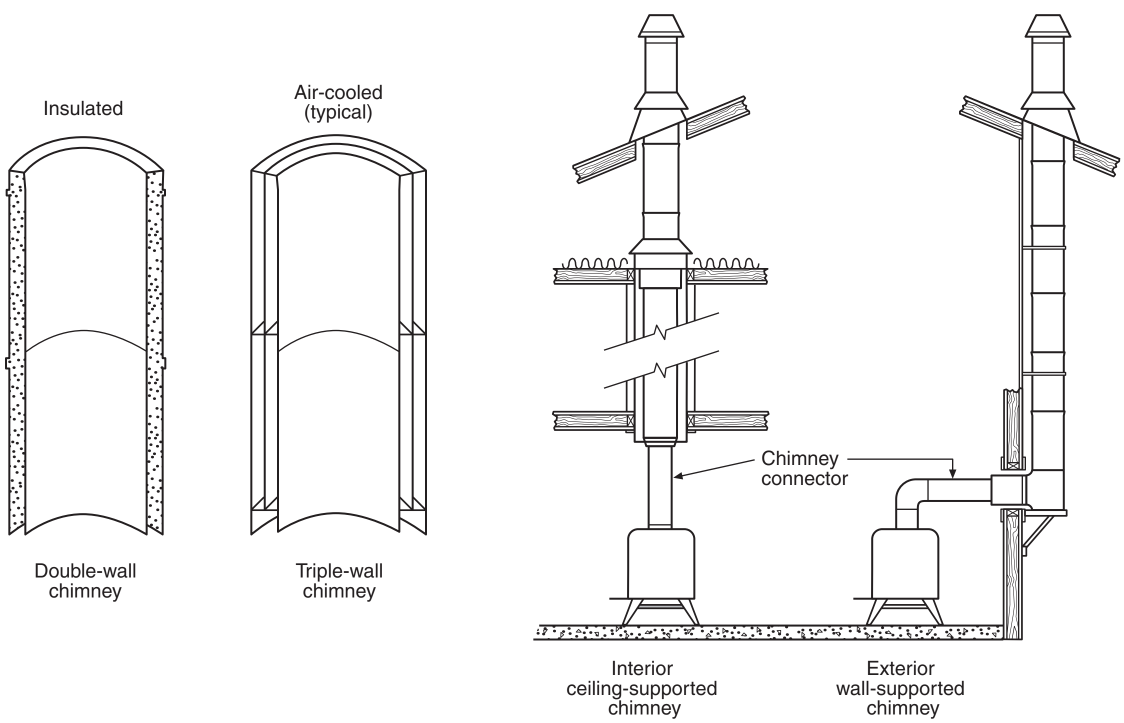

FIGURE 5.1.1(a) Typical Factory-Built Chimney Installation in a Single-Family Residence.

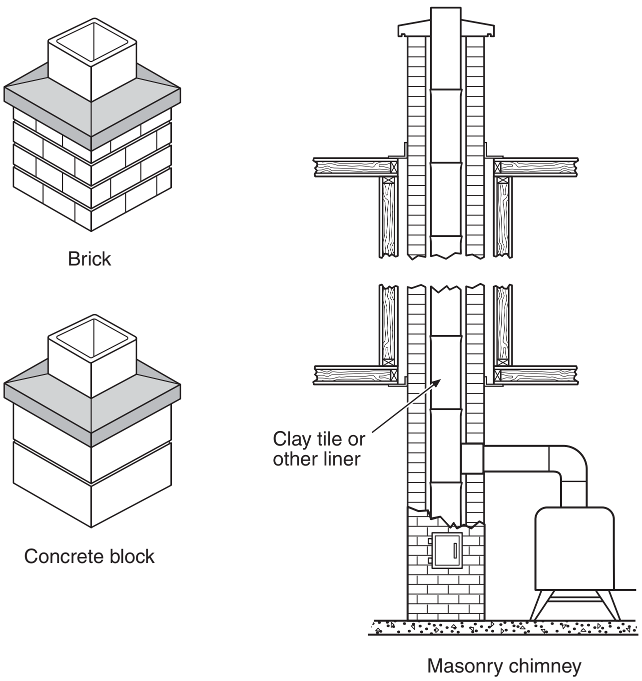

FIGURE 5.1.1(b) Masonry Chimney.

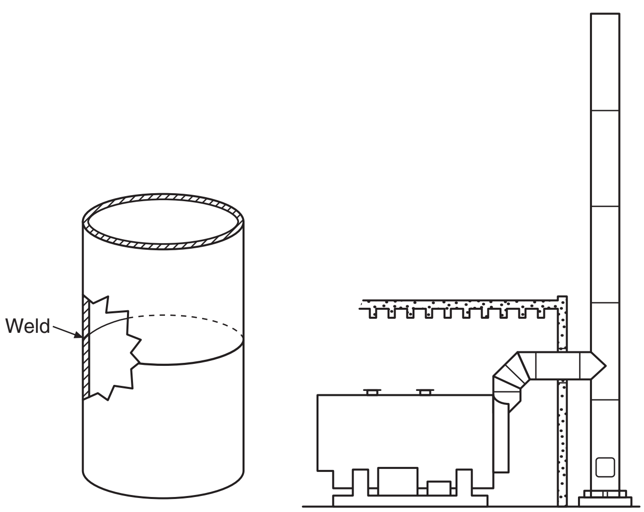

FIGURE 5.1.1(c) Typical Unlisted Metal Chimney Installation in a Commercial or Industrial Application.

5.2.2.2 Unlisted metal chimneys shall not be installed in one- and two-family dwellings.

5.2.3 Vents.

5.2.3.1 A vent shall be used only where appliances are listed for use with a vent.

5.2.3.2 The vent type shall be selected according to Table 5.2.3.2.

Chapter 6 Factory-Built Chimneys and Chimney Units

6.1 Type and Installation.

6.1.1 General. Factory-built chimneys and chimney units shall be listed and installed in accordance with the temperature and pressure conditions of the listing and the manufacturer's instructions.

6.1.2 Temperature and Pressure Limits. Flue gas temperatures and static pressures within the chimney shall not exceed the limits employed during listing tests.

6.1.3 Listing Requirements.

6.1.3.1 Factory-built chimneys shall comply with the requirements of ANSI/UL 103, *Standard for Factory-Built Chimneys for Residential Type and Building Heating Appliances*, or of ANSI/UL 959, *Standard for Medium Heat Factory-Built Appliance Chimneys*.

6.1.3.2* Factory-built chimneys for use with wood-burning appliances shall comply with the Type HT requirements of ANSI/UL 103, *Standard for Factory-Built Chimneys for Residential Type and Building Heating Appliances*.

6.1.3.3 Chimneys for factory-built fireplaces shall meet the requirements of ANSI/UL 127, *Standard for Factory-Built Fireplaces*.

6.1.3.4 Engineered appliance-venting systems that have been listed to operate without producing combustible deposits to the venting system shall be installed in accordance with the conditions of their listing and the manufacturer's instructions.

6.1.3.5 Open-front masonry fireplaces shall be permitted to use listed residential-type and building heating appliance chimneys without the Type HT designation.

6.1.4 Rated Enclosures. Factory-built chimneys that pass through floors of buildings requiring the protection of vertical openings shall be enclosed with approved walls having a fire resistance rating of not less than 1 hour where such chimneys are located in a building less than four stories in height and not less than 2 hours where such chimneys are located in a building four or more stories in height.

6.1.4.1* The enclosure shall not be constructed from any type of duct wrap or fire-rated duct wrap.

6.1.5 Decorative Shrouds. Unlisted decorative shrouds shall not be permitted at the termination of a factory-built chimney.

All listed gas appliances with draft hoods and other Category I gas appliances listed for use with Type B vents, such as: Central furnaces Duct furnaces Floor furnaces Heating boilers Ranges, residential and low-heat gas Built-in ovens Vented wall furnaces Room heaters Water heaters Horizontal furnaces Unit heaters Decorative appliances (gas fireplaces)	Vented wall furnaces listed for use with Type BW vents only	Listed Categories II, III, and IV gas appliances and Category I appliances listed for use with Special Gas Vents	Low-temperature flue gas appliances listed for use with Type L vents Gas appliances shown under Column I	Incinerators used outdoors, in open sheds, breezeways, or carports as provided in Section 8.2 Gas appliances shown under Column I Listed residential and low-heat gas appliances without draft hoods and unlisted residential and low-heat gas appliances with or without draft hoods	Listed pellet-burning appliances listed for use with pellet vents
Vent Type					
Listed Type B Gas Vent	**Listed Type BW Gas Vent**	**Listed Special Gas Vent**	**Listed Type L Vent**	**Unlisted Single-Wall Metal Pipe***	**Listed Pellet Vent**

Note: See Chapter 10 for requirements.
*See 10.6.4 for limitations on unlisted single-wall metal pipe.

6.2 Use. Factory-built chimneys shall be permitted to be used for exhaust systems and ducting from hoods, industrial ovens, furnaces, and process equipment of any temperature classification *(see Table 5.2.2.1)*, provided the system is engineered so that gas temperatures and pressures do not exceed the applicable limit for the type of chimney.

6.3* Sizing. Factory-built chimneys shall be sized and configured in accordance with the appliance and chimney manufacturers' instructions or approved methods.

6.4 Installation. Factory-built chimneys and chimney units installed through insulation or areas to be insulated shall be separated by a physical barrier to establish and maintain the minimum air space clearance required by the chimney manufacturer.

Chapter 7 Masonry Chimneys

7.1 General Requirements.

7.1.1 Support.

7.1.1.1 Masonry chimneys shall be supported on properly designed foundations of masonry or reinforced Portland or refractory cement concrete or on noncombustible material having a fire resistance rating of not less than 3 hours.

7.1.1.2 Such supports shall be independent of the building construction, and the load shall be transferred to the ground.

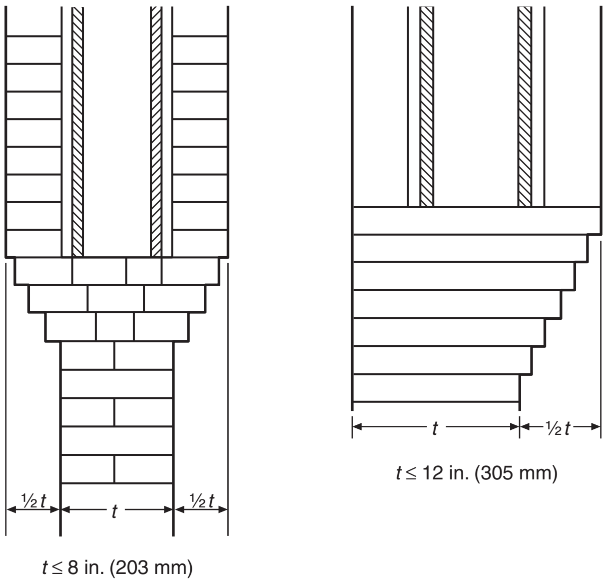
7.1.2 Corbeling. Individual and maximum projections of corbels in masonry chimneys shall comply with the requirements of this section. *[See Figure 7.1.2(a) through Figure 7.1.2(d).]*

7.1.2.1 Corbeling limitations shall be permitted to be varied for engineered, reinforced, brick masonry construction.

7.1.2.2 Individual corbels occurring at any point within a masonry chimney shall not exceed one-half the individual masonry unit height or one-third the thickness.

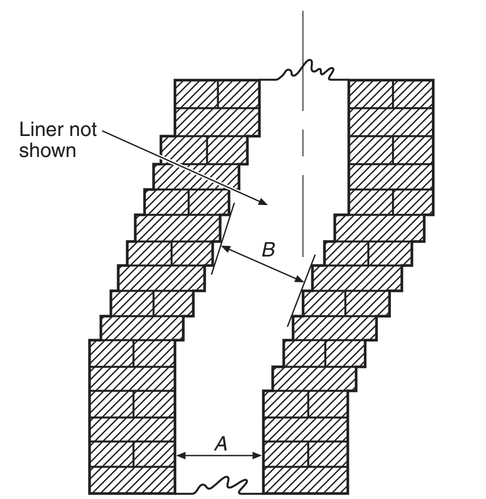
7.1.2.3 The following shall apply to masonry chimney supports:

(1) They shall be permitted to be formed by corbeling from a wall that is not less than 12 in. (305 mm) in thickness to form a maximum total projection of not more than one-half the wall thickness.
(2) Where the corbeling specified in 7.1.2.3(1) projects equally on each side of the wall, the masonry chimney support shall be permitted to be formed by corbeling



Note: t = masonry unit thickness.

FIGURE 7.1.2(a) Corbels for Supporting Chimneys.



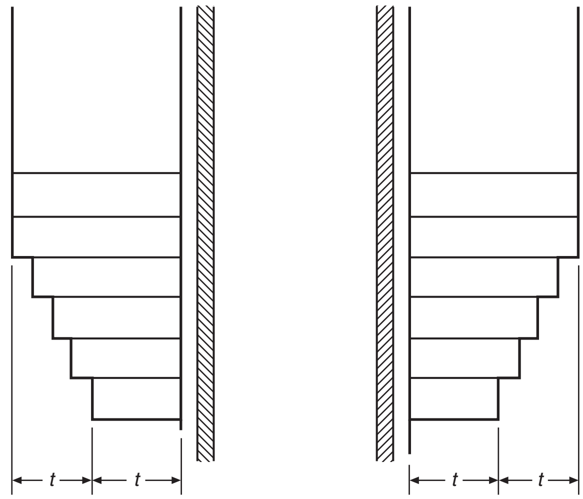
Chimney offset construction — centerline of upper flue does not fall beyond center of lower flue wall. Chimney size, A, and offset size, B, are equal.

FIGURE 7.1.2(b) Corbels to Change Chimney Direction.

from a wall that is not less than 8 in. (203 mm) in thickness to form a maximum total projection on each side of the wall that is not more than one-half the wall thickness.

7.1.2.4 Corbeling used to change the direction of a masonry chimney shall have a maximum offset so that the centerline of the upper flue does not fall beyond the center of the lower flue wall. The cross-sectional area of the flue shall not be reduced throughout the offset.

7.1.2.5 Corbeling used to increase the chimney wall thickness shall have a maximum total projection that does not exceed the thickness of the chimney wall.



Note: t = masonry unit thickness.

FIGURE 7.1.2(c) Corbels to Increase Chimney Wall Thickness.

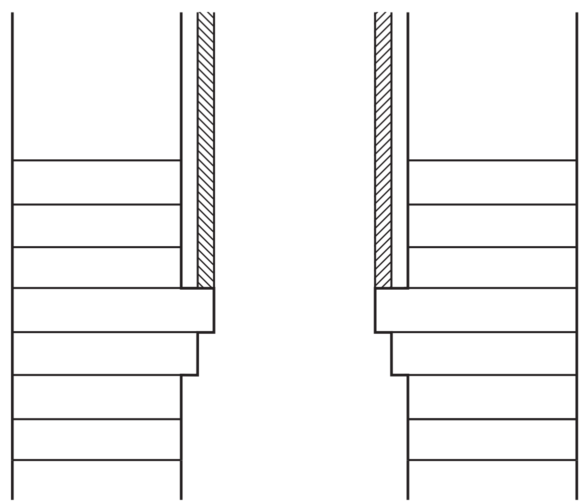


FIGURE 7.1.2(d) Corbels to Support Flue Lining.

7.1.2.6 Corbeled or solid masonry shall be provided in masonry chimneys to support the entire perimeter of flue liners.

7.1.2.7 Where a flue is constructed of two flue liners without a separation, three sides of each flue liner shall be supported entirely on corbeled masonry.

7.1.2.8 Corbels shall be made with solid units, and, where corbels are located on the walls of hollow masonry units, there shall be no fewer than three courses of solid masonry units below the corbels.

7.1.2.9 Corbeling used to incorporate wall pass-through shall be constructed in accordance with 7.1.2.

7.1.3 Change in Size or Shape of Flue at Combustible Members. A chimney flue shall not change in size or shape within 6 in. (152 mm) above or below any point where the chimney passes through combustible floor, ceiling, or roof components.

7.1.4 Cleanout Openings.

7.1.4.1 Cleanout openings shall be provided in all chimney flues serving freestanding appliances.

7.1.4.2 Cleanout openings shall be equipped with ferrous metal, stainless steel, precast cement, or other approved noncombustible doors and frames arranged to remain tightly closed and secured when not in use.

7.1.4.3 The lower edge of a cleanout opening inside a building shall be a minimum of 16 in. (406 mm) above the lowest accessible floor level.

7.1.4.4 The lower edge of a cleanout opening located outside a building shall be a minimum of 16 in. (406 mm) above grade, provided the cleanout opening is below the lowest chimney connector entrance.

7.1.4.5 Cleanout openings and doors shall not be obstructed. Combustible material located or projected beyond the face of the chimney shall be kept a minimum of 18 in. (457 mm) away from the cleanout opening.

7.1.4.6 Cleanout doors shall be permanently marked with a message equivalent to the following:

WARNING: DO NOT OBSTRUCT. KEEP COMBUSTIBLE MATERIAL AT LEAST 18 in. (457 mm) AWAY FROM THIS DOOR.

7.1.4.7 Listed cleanout doors shall be installed in accordance with the terms of their listing and the manufacturer's instructions.

7.1.5 Chimney Flue.

7.1.5.1 The base of the chimney flue shall start at a point at least 6 in. (152 mm) but not more than 12 in. (305 mm) below the bottom edge of the cleanout door opening.

7.1.5.2 Any space within the chimney below the level of the flue base shall be filled with noncombustible masonry material, mortar, concrete, or sand and topped with a wash or a cap that prevents the entry of moisture or creosote.

7.1.6 Firestopping.

7.1.6.1 Gaps between firestopping and the chimney shall not exceed $\frac{1}{16}$ in. (1.6 mm).

7.1.6.2 All spaces between chimneys and the floors and ceilings through which the chimneys pass shall remain fully open but shall be firestopped with noncombustible material.

7.1.6.3 The firestopping of spaces between chimneys and wood joists, beams, or headers shall be of galvanized steel not less than 26 gauge [0.019 in. (0.483 mm)] thick or of noncombustible sheet material not more than $\frac{1}{2}$ in. (12.7 mm) thick.

7.1.7 Smoke Test. Masonry chimneys shall be proved tight by a smoke test after construction and before being put into use.

7.1.8 Structural Design.

7.1.8.1 Chimneys shall be designed, anchored, supported, and reinforced as required in this standard.

7.1.8.2 A chimney shall not support any structural load other than its own weight, unless designed to act as a supporting member.

7.1.8.3 Seismic Reinforcing.

7.1.8.3.1 Reinforcement shall not be required in Seismic Design Category A, B, or C.

7.1.8.3.2 In structures of Seismic Design Category D, fireplaces with chimneys up to 40 in. (1016 mm) wide, four No. 4 continuous vertical bars, anchored in the foundation, shall be placed in the concrete, between wythes of solid masonry or within the cells of hollow unit masonry and grouted in accordance with ASTM C476, *Standard Specification for Grout for Masonry*.

7.1.8.3.2.1 For fireplaces with chimneys greater than 40 in. (1016 mm) wide, two additional No. 4 vertical bars shall be provided for each additional 40 in. (1016 mm) in width or fraction thereof.

7.1.8.3.2.2 Vertical reinforcement shall be placed enclosed within $\frac{1}{4}$ in. (6.4 mm) ties or other reinforcing of equivalent net cross-sectional area, spaced not to exceed 18 in. (457 mm) on center in concrete, or placed in the bed joints of unit masonry at a minimum of every 18 in. (457 mm) of vertical height.

7.1.8.3.2.3 Two such ties shall be provided at each bend in the vertical bars.

7.1.8.3.3 In structures of Seismic Design Category E or F, masonry and concrete chimneys shall be reinforced in accordance with the requirements of Sections 43.1 through 43.8 of *NFPA 5000*.

7.1.8.4 Seismic Anchorage.

7.1.8.4.1 Seismic anchorage shall not be required in Seismic Design Category A, B, or C.

7.1.8.4.2 In structures of Seismic Category D, masonry and concrete chimneys shall be anchored at each floor, ceiling, or roof line more than 6 ft (1.8 m) above grade except where constructed completely within the exterior walls.

7.1.8.4.3 Two $\frac{3}{16}$ in. by 1 in. (4.8 mm by 25 mm) straps shall be embedded a minimum of 12 in. (305 mm) into the chimney.

7.1.8.4.3.1 Straps shall be hooked around the outer bars and extend 6 in. (152 mm) beyond the bend.

7.1.8.4.3.2 Each strap shall be fastened to a minimum of four floor joists with two $\frac{1}{2}$ in. (12.7 mm) bolts.

7.1.8.5 Chimney design shall consider seismic and wind loading.

7.1.8.6 Masonry chimneys shall be permitted to be constructed as part of the masonry walls or reinforced concrete walls of buildings.

7.1.9 Thimbles.

7.1.9.1 Thimbles for chimneys or vent connectors shall be of fireclay *(see ASTM C315, Standard Specification for Clay Flue Liners and Chimney Pots)*, galvanized steel of a minimum thickness of 24 gauge [0.024 in. (0.61 mm)], or material of equivalent durability.

7.1.9.2 Thimbles shall be installed without damage to the liner.

7.1.9.3 The thimble shall extend through the wall to, but not beyond, the inner face of the liner and shall be cemented firmly to masonry.

7.1.9.4 Thimbles shall be located to provide pitch or rise of chimney or vent connectors.

7.1.9.5 Where the ceiling above the appliance is constructed of combustible material, the location of the thimble shall provide the minimum clearance required for the connector, as specified in Section 9.5.

7.1.9.6 The installation of thimbles through walls or partitions constructed of combustible materials shall conform with the requirements of Section 9.7.

7.1.10 Relining.

7.1.10.1 Where masonry chimneys are relined, the liner shall be listed or of approved material that resists corrosion, softening, or cracking from flue gases at temperatures appropriate to the class of chimney service.

7.1.10.2 Listed liner systems shall be installed in accordance with the listing.

7.1.10.3 Approved materials shall be installed in accordance with Section 7.2.

7.1.10.4 The relined chimney shall meet the requirements of the class of chimney service.

7.1.11* Sizing.

7.1.11.1 Masonry chimneys serving appliances shall be sized and configured in accordance with the appliance manufacturer's instructions, 13.4.4, or approved methods.

7.1.11.2 Masonry chimneys serving fireplaces shall be sized in accordance with the requirements of *ASHRAE Handbook: HVAC Systems and Equipment* or other approved methods.

7.1.11.3 Masonry chimneys serving fireplaces that are a minimum of 8 ft (2.44 m) in height above the top of the fireplace opening and are constructed with no offsets in the flue shall be permitted to be designed in accordance with 7.1.11.3.1 through 7.1.11.3.5.

7.1.11.3.1 Round chimney flues shall have a minimum net cross-sectional area of at least one-twelfth the fireplace opening.

7.1.11.3.2 Square chimney flues shall have a minimum net cross-sectional area of at least one-tenth the fireplace opening.

7.1.11.3.3 Rectangular and oval chimney flues with an aspect ratio of less than 2 to 1 shall have a minimum net cross-sectional area of at least one-tenth the fireplace opening.

7.1.11.3.4 Rectangular and oval chimney flues with an aspect ratio of 2 to 1 or more shall have a minimum net cross-sectional area of at least one-eighth the fireplace opening.

7.1.11.3.5 The aspect ratio shall be the ratio of the longer inside dimension to the shorter inside dimension.

7.1.12* Positive-Pressure Applications. Masonry chimneys used for positive internal pressure applications shall incorporate a lining system either listed for positive internal pressure applications or otherwise approved for such use.

7.2 Construction of Masonry Chimneys. Masonry chimneys shall be constructed as detailed in this section and Table 7.2.

Table 7.2 Construction, Termination, and Clearances for Masonry Chimneys

	Column															
	I		II		III	IV		V	VI		VII		VIII		IX	
	Chimney Wall Thickness				Chimney Liner (*See 7.2.2.3.*)				Termination				Minimum Air Space Clearances (*See 7.2.2.3.*)			
	Brick or Concrete		Rubble Stone			Thickness			Highest Point		Nearby Structures		Interior Chimney		Exterior Chimney	
Chimney Type	in.	mm	in.	mm	Type	in.	mm	Cement	ft	m	ft	m	in.	mm	in.	mm
Residential	4	102	12	305	Fireclay	$\frac{5}{8}$	16	Medium duty	3	0.91	2 within 10	0.61 3.05	2	51	1	25
Low-heat	8	203	12	305	Fireclay	$\frac{5}{8}$	16	Medium duty	3	0.91	2 within 10	0.61 3.05	2	51	2	51
Medium-heat	8	203	12	305	Fireclay brick	$4\frac{1}{2}$	114	Medium duty	10	3.05	10 within 25	3.05 7.6	4	102	4	102
High-heat	See 7.2.1.3.				Fireclay brick	$4\frac{1}{2}$	114	High duty	20	6.1	20 within 50	6.1 15.2	See 7.3.1.5.			

7.2.1 Construction.

7.2.1.1 Masonry chimneys shall be constructed of one of the following materials and laid with full, push-filled, head, and bed mortar joints:

(1) Solid masonry or solid, waterproofed, modular concrete blocks in nominal thicknesses not less than those specified in Table 7.2, Column I
(2) Reinforced Portland or refractory cement concrete in actual thicknesses not less than those specified in Table 7.2, Column I
(3) Rubble stone masonry in actual thicknesses not less than those specified in Table 7.2, Column II

7.2.1.2 Reinforced masonry chimneys for residential-type appliances shall be permitted to be constructed of hollow masonry units not less than 6 in. (152 mm) nominal thickness, with cells fully filled with mortar.

7.2.1.3 Masonry chimneys for high-heat appliances shall meet the following criteria:

(1) They shall be constructed with double walls of solid masonry or reinforced Portland or refractory cement concrete.
(2) Each double wall shall be not less than 8 in. (203 mm) thick with an air space of not less than 2 in. (51 mm) between walls.

7.2.2 Chimney Lining.

7.2.2.1 Masonry chimneys shall be lined.

7.2.2.2 The selection of the lining material shall be appropriate for the class of chimney service and the type of appliance connected, in accordance with the terms of the appliance listing and the manufacturer's instructions.

7.2.2.3 Listed materials used as chimney linings shall be installed in accordance with the terms of their listings and the manufacturer's instructions.

7.2.2.4 The materials specified in 7.2.3 through 7.2.8 shall be permitted for the indicated class of chimney service.

7.2.3 Low-, Medium-, and High-Heat Appliances. The following materials shall be permitted for low-, medium-, and high-heat appliances (Table 5.2.2.1, Columns II, III, IV, and V):

(1) Clay flue lining complying with the requirements of ASTM C315, *Standard Specification for Clay Flue Liners and Chimney Pots*, or the equivalent, as specified in Table 7.2, Columns III and IV
(2) Fireclay brick complying with the requirements of ASTM C27, *Standard Classification of Fireclay and High-Alumina Refractory Brick*, or the equivalent, as specified in Table 7.2, Columns III and IV

7.2.4 Residential-Type and Building Heating Appliances. The following materials shall be permitted for residential-type and building heating appliances (Table 5.2.2.1, Columns I and II):

(1) Clay flue lining or fireclay brick complying with 7.2.3, as specified in Table 7.2, Columns III and IV
(2) Listed chimney lining systems
(3) Factory-built chimneys or chimney units listed for installation within masonry chimneys
(4) Other approved materials that resist corrosion, erosion, softening, or cracking from flue gases and condensate at temperatures up to 1800°F (982°C)

7.2.5 Category I Gas Appliances. The following materials shall be permitted for Category I gas appliances (Table 5.2.3.2, Column I):

(1) Chimney liners complying with 7.2.4
(2) Chimney lining systems listed for use with listed gas appliances with draft hoods and other Category I appliances listed for use with Type B vents *(See 7.2.9 for marking.)*
(3) Type B vents listed for installation within masonry chimneys *(See 7.2.9 for marking.)*

7.2.6 Categories II, III, and IV Gas Appliances. Special gas vents listed for installation within masonry chimneys shall be permitted (Table 5.2.3.2, Column III). *(See 7.2.9 for marking.)*

7.2.7 Pellet Fuel–Burning Appliances. The following materials shall be permitted for pellet fuel–burning appliances (Table 5.2.3.2, Column VI):

(1) Chimney liners complying with 7.2.4
(2) Pellet vents listed for installation within masonry chimneys *(See 7.2.9 for marking.)*

7.2.8 Listed or Approved Materials. Other materials listed for installation within masonry chimneys for the class of chimney service and for the appliance type shall be permitted. Other approved materials that resist corrosion, erosion, softening, or cracking from flue gases and condensate at temperatures appropriate for the class of chimney service and appliance type shall be permitted.

7.2.9 Notice of Usage.

7.2.9.1 Where a Type B gas vent, special gas vent, pellet vent, or other material not suitable for use under Columns I and II of Table 5.2.2.1 is used as a liner for a masonry chimney, the chimney shall be plainly and permanently identified by a label attached to the wall or ceiling or at another conspicuous location adjacent to the point where the connector enters the chimney.

7.2.9.2 The label shall read as follows or the equivalent:

"This [*type of product*] Is for [*type or category of appliance*] Appliances That Burn [*type of fuel*] Only. Do Not Connect Other Types of Appliances."

7.2.10 Fireclay Flue Liners.

7.2.10.1 Fireclay flue liners shall be installed ahead of the construction of the chimney as it is carried up.

7.2.10.2 Liners shall be bedded one on the other in a medium-duty, non-water-soluble calcium aluminate refractory cement mixture, or its equivalent.

7.2.10.3 Joints shall be left smooth on the inside.

7.2.10.4 Portland cement–bonded mixtures shall not be used.

7.2.11 Fireclay Brick Flue Liners. Fireclay brick flue liners shall be installed laid in full-width refractory mortar as specified in Table 7.2, Column V, or the equivalent.

7.2.12 Fireclay Flue Lining for Residential and Low-Heat Masonry Chimneys.

7.2.12.1 Fireclay flue lining for residential and low-heat masonry chimneys shall be separated from the chimney wall by a minimum of ½ in. (12.7 mm) and a maximum of 4 in. (102 mm) of air space.

7.2.12.2 The air space shall not be filled, and only enough mortar to make a good joint and hold the liners in position shall be used.

7.2.12.3 Where masonry chimneys are lined with a listed chimney liner system, the system shall be installed in accordance with the listing.

7.2.13 Installation of Fireclay Flue Liners.

7.2.13.1 The fireclay flue liner shall start at or below the base of the chimney flue and shall be supported by solid masonry.

7.2.13.2 The lining shall be carried up as nearly vertically as possible, with a maximum slope no greater than 30 degrees from the vertical.

7.2.13.3 The lining shall extend for the entire height of the chimney to a level not less than 2 in. (51 mm) above the crown, splay, or wash.

7.2.13.4 The crown, splay, or wash shall be constructed to allow for unrestricted vertical movement of the flue lining due to thermal expansion without allowing the introduction of moisture into the chimney.

7.2.14 Multiple Flues.

7.2.14.1 Where a chimney contains more than one flue, a separation shall be provided between adjacent flues.

7.2.14.2 The separation shall be of solid masonry wythes (partitions) bonded or securely tied to the chimney walls and constructed according to one of the following:

(1) Not less than 4 in. (102 mm), nominal, in thickness
(2) Of reinforced Portland or refractory cement concrete not less than 4 in. (102 mm), actual, in thickness

7.2.14.3 Where two flues are used to vent a single fireplace or appliance, the provisions of 7.2.14.1 shall not be required.

7.2.14.4 Multiple flues in one chimney shall not be permitted for medium-heat appliances, high-heat appliances, or commercial and industrial incinerators.

7.2.14.5 For chimney liners that have been listed for use as multiple flues installed in accordance with the terms of the listing, the provisions of 7.2.14.1 shall not be required.

7.3 Clearance from Combustible Material.

7.3.1 Minimum Air Space.

7.3.1.1 The minimum air space clearance between interior masonry chimneys (where any portion of the chimney is located within the exterior wall of the building) and combustible materials shall be at least the distance specified in Table 7.2, Column VIII.

7.3.1.2 The minimum air space clearance between exterior masonry chimneys (where the chimney is located completely outside the exterior wall of the building, excluding the soffit or cornice area) and combustible material shall be at least the distance specified in Table 7.2, Column IX.

7.3.1.3* The air space shall not be filled.

7.3.1.4 For residential and low-heat chimneys, noncombustible trim shall be permitted to be used to prevent the entry of debris into the air space.

7.3.1.5 Masonry chimneys for high-heat appliances shall have clearance from buildings and structures based on good engineering practice and acceptable to the AHJ to avoid overheating combustible material, to allow inspection and maintenance operations on the chimney, and to avoid the danger of burns to persons.

7.3.2 Listed Chimney Liners. Chimneys constructed with listed chimney liners shall be built with clearances in conformance with the listing of the liner system.

7.4 Masonry Chimneys for Incinerators.

7.4.1 In addition to the requirements in Section 7.1 through Section 7.3, masonry chimneys for incinerators shall meet the requirements of 7.4.2 through 7.4.3.3.

7.4.2 Chute-Fed Incinerators. Chute-fed incinerators shall meet the requirements of NFPA 82.

7.4.3 Commercial and Industrial Incinerators. Masonry chimneys for commercial and industrial incinerators shall be supported on foundations of one of the following:

(1) Masonry
(2) Reinforced Portland cement concrete
(3) Refractory cement concrete
(4) Noncombustible material having a fire resistance rating of not less than 3 hours

7.4.3.1 Foundations and supports shall be independent of the building construction and transfer the load to the ground.

7.4.3.2 Chimneys shall be permitted to be supported on incinerator walls if the incinerator foundation and walls are built to support the load imposed and shall be constructed to prevent excessive stress on the roof of the combustion chamber.

7.4.3.3 The terminus of the chimney for commercial and industrial incinerators shall be equipped with an approved spark arrester if the incinerator does not include effective means for arresting sparks and fly ash. *(See NFPA 82.)*

Chapter 8 Unlisted Metal Chimneys (Smokestacks) for Nonresidential Applications

8.1 General Requirements.

8.1.1 One- and Two-Family Dwellings. Single-wall metal chimneys or unlisted metal chimneys shall not be used inside or outside one- and two-family dwellings.

8.1.2 Construction.

8.1.2.1 Unlisted metal chimneys shall be constructed of steel or cast iron.

8.1.2.2 Sheet steel shall have a thickness not less than that indicated in Table 8.1.2.2.

8.1.3 Connection and Support.

8.1.3.1 Unlisted metal chimneys shall be attached by one of the following:

(1) Rivets
(2) Welds
(3) Bolts

Table 8.1.2.2 Minimum Thickness of Sheet Steel Chimneys

	Minimum Thickness		Area		Equivalent Round Diameter	
Gauge	in.	mm	in.^{2}	m^2	in.	mm
16	0.053	1.35	≤154	≤0.0994	≤14	≤356
14	0.067	1.70	155 to 201	0.0999 to 0.1296	>14 to ≤16	>356 to ≤406
12	0.093	2.36	202 to 254	0.1303 to 0.1638	>16 to ≤18	>406 to ≤457
10	0.123	3.12	>254	>0.1638	>18	>457

Note: Regardless of minimum thicknesses specified in this table, the thickness of sheet metal must be adequate to meet the requirements of 8.1.3.

8.1.3.2 Chimneys shall be securely supported and constructed in accordance with the following:

(1) Strength to resist stresses due to steady or gusting wind loads
(2) Adequate anchoring, bracing, and inherent strength to withstand seismic and wind-induced vibrational stresses
(3) Proper material thickness for durability considering fuel analysis, gas temperature, and exposure
(4) Security against leakage of flue gases under positive pressure
(5) Allowance for thermal expansion of breeching and vertical sections

8.1.4 Prohibited Uses. Unlisted metal chimneys shall not be used inside ventilating ducts.

8.1.5 Clearances.

8.1.5.1 Unlisted metal chimneys shall have clearance from buildings and structures to avoid heating combustible material to a temperature in excess of 90°F (50°C) above ambient and to allow inspection and maintenance operations on the chimney.

8.1.5.2 Chimneys shall be located or shielded to avoid the danger of burns to persons.

8.1.6 Foundations and Supports.

8.1.6.1 Unlisted metal chimneys shall be independent of the building construction, transfer the load to the ground, and be supported on foundations of one of the following:

(1) Masonry
(2) Reinforced Portland cement concrete
(3) Refractory cement concrete
(4) Noncombustible material having a fire resistance rating of not less than 3 hours

8.1.6.2 An unlisted metal chimney also can be supported at intervals by the building structure, in which case expansion joints shall be provided at each support level.

8.1.6.3 All joints shall be liquidtight or of a design that allows liquid to drain to the interior of the chimney.

8.1.7 Flue Gases Below 350°F (177°C). Unlisted metal chimneys serving appliances producing flue gases having a temperature below 350°F (177°C) at the entrance to the chimney at full load or partial load shall be one of the following:

(1) Constructed of or lined with acid- and condensate-resistant stainless steel
(2) Lined with acid- and condensate-resistant refractory material or other approved materials

8.1.8* Sizing. Unlisted metal chimneys shall be sized and configured in accordance with the appliance manufacturer's instructions or approved methods.

8.2 Unlisted Metal Chimneys for Residential-Type or Low-Heat Appliances.

8.2.1 Termination (Height).

8.2.1.1 Unlisted metal chimneys for residential-type or low-heat appliances shall extend to the following:

(1) At least 3 ft (0.92 m) above the highest point at which they pass through the roof of a building
(2) At least 2 ft (0.61 m) higher than any portion of a building within 10 ft (3.1 m) *[See Figure 4.2(a).]*

8.2.1.2 The outlet of an unlisted metal chimney for residential-type and low-heat appliances equipped with a mechanical exhaust system shall be permitted to terminate at a location that meets the following stipulations:

(1) Not less than 3 ft (0.92 m) from an adjacent building or building opening
(2) At least 10 ft (3.1 m) abovegrade or above walkways

8.2.1.3 The outlet shall be arranged such that the flue gases are not directed so that they jeopardize people, overheat combustible structures, or enter building openings in the vicinity of the outlet.

8.2.2 Clearances.

8.2.2.1 Exterior.

8.2.2.1.1 Exterior unlisted metal chimneys used only for residential-type or low-heat appliances shall have a clearance of not less than 18 in. (457 mm) from a wall of wood frame construction and from any combustible material.

8.2.2.1.2 Exterior unlisted metal chimneys over 18 in. (457 mm) in diameter shall have a clearance of not less than 4 in. (102 mm) from a building wall of noncombustible construction.

8.2.2.1.3 Exterior unlisted metal chimneys 18 in. (457 mm) or less in diameter shall have a clearance of not less than 2 in. (51 mm) from a building wall of noncombustible construction.

8.2.2.1.4 An unshielded, unlisted metal chimney erected on the exterior of a building shall not be installed less than 2 ft (0.61 m) from any door, window, or walkway.

8.2.2.2 Interior.

8.2.2.2.1 Where an unlisted metal chimney extends through any story(ies) of a building above that in which the appliances connected to the chimney are installed, it shall be enclosed in those upper stories within a continuous enclosure constructed of noncombustible materials complying with the following:

(1) The enclosure shall extend from the ceiling of the appliance room to or through the roof so that it maintains the integrity of the fire separations required by the applicable building code provisions.
(2) Where the building is less than four stories in height, the enclosure walls shall have a fire resistance rating of not less than 1 hour.
(3) Where the building is four stories or more in height, the enclosure walls shall have a fire resistance rating of not less than 2 hours.
(4) The enclosure walls shall provide a space not less than 12 in. (305 mm) on all sides of the chimney sufficient to allow inspection and repair.
(5) Only doorways for inspection purposes equipped with approved self-closing fire doors shall be permitted.

8.2.2.2.2 Where an unlisted metal chimney serving only residential-type or low-heat appliances is located in the same story of a building as that story in which the appliances connected thereto are located, it shall have a clearance of not less than 18 in. (457 mm) from a wall of wood frame construction and from any combustible material.

8.2.2.2.3 Interior unlisted metal chimneys over 18 in. (457 mm) in diameter shall have a clearance of not less than 4 in. (102 mm) from a building wall of noncombustible construction.

8.2.2.2.4 Interior unlisted metal chimneys 18 in. (457 mm) or less in diameter shall have a clearance of not less than 2 in. (51 mm) from a building wall of noncombustible construction.

8.2.2.2.5 Where an unlisted metal chimney serving only residential-type or low-heat appliances passes through a roof constructed of combustible material, it shall be guarded by a ventilating thimble of galvanized steel or approved corrosion-resistant metal that adheres to the following criteria:

(1) Is not less than 0.024 in. (0.61 mm) in thickness
(2) Extends not less than 9 in. (229 mm) below and 9 in. (229 mm) above the roof construction

8.2.2.2.6 Where combustible material in the roof construction is cut away to provide not less than 18 in. (457 mm) clearance on all sides of the chimney, using entirely noncombustible material to close such an opening, the requirements of 8.2.2.2.5 shall not apply.

8.2.2.2.7 The ventilating thimble shall be constructed of galvanized steel not less than 24 gauge [0.024 in. (0.61 mm)] in thickness and provide the following:

(1) A clearance of not less than 9 in. (229 mm) from the chimney surface to the nearest combustibles
(2) A minimum 1 in. (25 mm) air space between the thimble wall and combustible material
(3) A ventilated space between the chimney and the thimble wall *(See Figure 8.2.2.2.7.)*

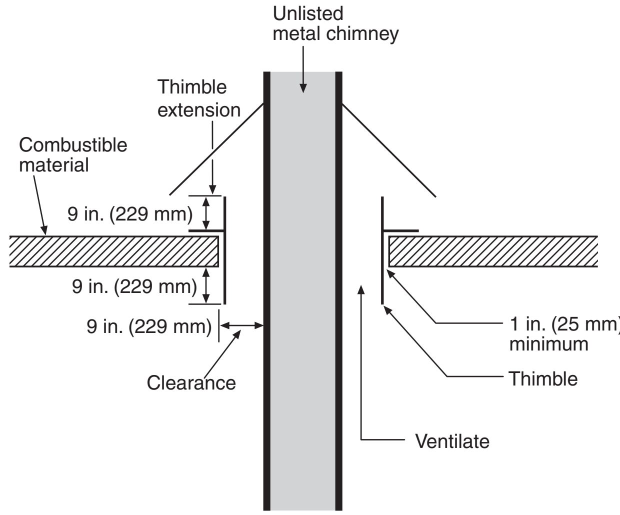

FIGURE 8.2.2.2.7 Ventilating Thimble.

8.3 Unlisted Metal Chimneys for Medium-Heat Appliances.

8.3.1 Construction. Unlisted metal chimneys serving medium-heat appliances shall be constructed as follows:

(1) Lined with medium-duty fireclay brick (ASTM C27, *Standard Classification of Fireclay and High-Alumina Refractory Brick*) or its equivalent
(2) Laid in medium-duty refractory mortar (ASTM C199, *Standard Test Method for Pier Test for Refractory Mortars*) or its equivalent

8.3.1.1 The lining shall be at least 2 in. (51 mm) thick for chimneys having a diameter or greatest cross-sectional dimension of 18 in. (457 mm) or less.

8.3.1.2 The lining shall have a thickness of not less than 4 in. (102 mm) laid on a full-width bed for chimneys having a diameter or greatest cross-sectional dimension greater than 18 in. (457 mm), and the following criteria also shall be met:

(1) The lining shall start 2 ft (0.61 m) or more below the lowest chimney connector entrance.
(2) The lining shall extend to a height of at least 25 ft (7.6 m) above the highest chimney connector entrance.
(3) Chimneys terminating 25 ft (7.6 m) or less above a chimney connector entrance shall be lined to the top.

8.3.2 Termination (Height). Unlisted metal chimneys for medium-heat appliances shall extend not less than 10 ft (3.1 m) higher than any portion of any building within 25 ft (7.6 m).

8.3.3 Clearances.

8.3.3.1 Exterior.

8.3.3.1.1 Exterior unlisted metal chimneys used for medium-heat appliances shall have a clearance of not less than 24 in. (0.61 m) from a wall of wood frame construction and from any combustible material.

8.3.3.1.2 Exterior unlisted metal chimneys over 18 in. (457 mm) in diameter shall have a clearance of not less than 4 in. (102 mm) from a building wall of noncombustible construction.

8.3.3.1.3 Exterior unlisted metal chimneys 18 in. (457 mm) or less in diameter shall have a clearance of not less than 2 in. (51 mm) from a building wall of noncombustible construction.

8.3.3.1.4 An uninsulated, unlisted metal chimney erected on the exterior of a building shall not be installed less than 24 in. (0.61 m) from any door or window or from any walkway.

8.3.3.2 Interior.

8.3.3.2.1 Where an unlisted metal chimney extends through any story(ies) of a building above that story in which the appliances connected to the chimney are installed, it shall be enclosed in those upper stories within a continuous enclosure constructed of noncombustible materials complying with the following:

(1) The enclosure shall extend from the ceiling of the appliance room to or through the roof so that it maintains the integrity of the fire separations required by the applicable building code provisions.
(2) Where the building is less than four stories in height, the enclosure walls shall have a fire resistance rating of not less than 1 hour.
(3) Where the building is four stories or more in height, the enclosure walls shall have a fire resistance rating of not less than 2 hours.
(4) The enclosure walls shall provide a space not less than 12 in. (305 mm) on all sides of the chimney to allow inspection and repair.
(5) Only doorways for inspection purposes equipped with approved self-closing 1-hour fire doors shall be permitted.

8.3.3.2.2 Where an unlisted metal chimney serving a medium-heat appliance passes through a roof constructed of combustible material, it shall be as follows:

(1) Guarded by a ventilating thimble of galvanized steel or approved corrosion-resistant metal extending not less than 9 in. (229 mm) below and 9 in. (229 mm) above the roof construction
(2) Of a size that allows a minimum clearance of 18 in. (457 mm) on all sides of the chimney

8.3.3.2.3 Where an unlisted metal chimney serving medium-heat appliances is located in the same story of a building as that story in which the appliances connected thereto are located, it shall have a clearance of not less than 36 in. (0.92 m) from a wall of wood frame construction and from any combustible material.

8.3.3.2.4 Interior unlisted metal chimneys over 18 in. (457 mm) in diameter shall have a clearance of not less than 4 in. (102 mm) from a building wall of noncombustible construction.

8.3.3.2.5 Interior unlisted metal chimneys 18 in. (457 mm) or less in diameter shall have a clearance of not less than 2 in. (51 mm) from a building wall of noncombustible construction.

8.4 Unlisted Metal Chimneys for High-Heat Appliances.

8.4.1 Construction.

8.4.1.1 Unlisted metal chimneys for high-heat appliances shall be lined with high-duty fireclay brick (ASTM C27, *Standard Classification of Fireclay and High-Alumina Refractory Brick*) or its equivalent, not less than 4 in. (102 mm) thick, laid on a full-width bed in high-duty refractory mortar (ASTM C199, *Standard Test Method for Pier Test for Refractory Mortars*) or its equivalent.

8.4.1.2 The lining shall start 2 ft (0.61 m) or more below the lowest chimney connector entrance, and the following criteria also shall be met:

(1) The lining shall extend to a height of at least 25 ft (7.6 m) above the highest chimney connector entrance.
(2) Chimneys terminating 25 ft (7.6 m) or less above a chimney connector entrance shall be lined to the top.

8.4.2 Termination (Height). Unlisted metal chimneys for high-heat appliances shall extend not less than 20 ft (6.1 m) higher than any portion of any building within 50 ft (15.3 m).

Chapter 9 Chimney Connectors and Vent Connectors

9.1 Connectors Required. Connectors shall be used to connect appliances to the vertical chimney or vent unless the chimney or vent is attached directly to the appliance.

9.2 Materials.

9.2.1 Connectors shall be as follows:

(1) Made of noncombustible, corrosion-resistant material
(2) Capable of withstanding the flue gas condensate, pressures, and temperatures produced by the appliances
(3) Of sufficient thickness to withstand physical damage

9.2.2 Connectors for residential-type appliances shall conform to the requirements of this chapter.

9.2.2.1 Vent connectors for listed gas appliances and appliances listed for use with Type B gas vents that are installed in attics shall be one of the following:

(1) Type B or Type L vent material
(2) Listed vent connector material having at least an equivalent insulating value

9.2.2.2 Vent connectors for appliances that are listed for use with Type B gas vents and for appliances with draft hoods and equipped with listed conversion burners and that are not installed in attics shall be of Type B or Type L material or other material listed for use as connectors or shall be smooth interior-wall metal pipe having strength and resistance to heat and corrosion equivalent to that of galvanized sheet steel not less than 0.018 in. (0.46 mm) thick, aluminum (1100 or 3003 alloy or the equivalent) not less than 0.027 in. (0.69 mm) thick, or stainless steel not less than 0.012 in. (0.31 mm) thick.

9.2.2.2.1 Where reduced clearance is necessary, listed reduced clearance connectors shall be permitted to be used if they are installed in accordance with the manufacturer's installation instructions.

9.2.2.3 Connectors for oil appliances, solid fuel–burning appliances, domestic-type incinerators, and gas appliances other than those specified in 9.2.2.1 and 9.2.2.2 shall be constructed of one of the following:

(1) Factory-built chimney material
(2) Type L vent material
(3) Steel pipe having resistance to corrosion and heat not less than that of pipe specified in Table 9.2.2.3

9.2.3 Connectors for low-heat appliances shall be constructed of one of the following:

(1) Listed factory-built chimney material
(2) Steel pipe having resistance to corrosion and heat and not less than the thickness of steel pipe specified in Table 9.2.2.3

9.2.4 Connectors for medium-heat appliances and commercial and industrial incinerators shall conform to the requirements

Table 9.2.2.3 Metal Thickness for Steel Pipe Connectors

Diameter of Connector		Sheet Gauge No.	Minimum Thickness	
in.	mm		in.	mm
<6	<152	26	0.019	0.48
≥6 to ≤10	≥152 to ≤254	24	0.024	0.61
>10 to ≤16	>254 to ≤406	22	0.029	0.74
>16	>406	16	0.056	1.42

of 9.2.4.1 through 9.2.4.2.2 and shall be constructed of one of the following:

(1) Listed medium-heat chimney sections
(2) Steel not lighter than that designated for unlisted metal chimneys in Table 8.1.2.2

9.2.4.1 Connector sections of listed medium-heat chimneys shall be joined using one of the following:

(1) Continuous welds
(2) Flanges
(3) Couplings

9.2.4.2 Steel connectors shall be lined with medium-duty fireclay brick (ASTM C27, *Standard Classification of Fireclay and High-Alumina Refractory Brick*) laid in medium-duty refractory mortar (ASTM C199, *Standard Test Method for Pier Test for Refractory Mortars*) or the equivalent.

9.2.4.2.1 The lining shall be at least 2 in. (51 mm) thick for connectors having an inside diameter or greatest inside cross-sectional dimension of 18 in. (457 mm) or less.

9.2.4.2.2 The lining shall be at least 4 in. (102 mm) thick laid on the 4 in. (102 mm) bed for connectors having an inside diameter or greatest inside cross-sectional dimension greater than 18 in. (457 mm).

9.2.5 Metal connectors for high-heat appliances shall conform to the requirements of 9.2.5.1 and 9.2.5.2.

9.2.5.1 Metal connectors for high-heat appliances shall be made of steel not lighter than that designated for chimneys in Table 8.1.2.2.

9.2.5.2 The connectors shall be lined with high-duty fireclay brick (ASTM C27, *Standard Classification of Fireclay and High-Alumina Refractory Brick*) or its equivalent having a thickness of not less than 4 in. (102 mm) laid on the 4 in. (102 mm) bed in high-duty refractory mortar (ASTM C199, *Standard Test Method for Pier Test for Refractory Mortars*) or its equivalent.

9.2.6 Masonry connectors or breeching shall be made of refractory material equivalent in resistance to heat and corrosion to high-duty fireclay brick (ASTM C27, *Standard Classification of Fireclay and High-Alumina Refractory Brick*) not less than 4 in. (102 mm) thick.

9.3 Length. A connector shall be as short and straight as practicable. The appliance shall be located as close as practicable to the chimney or vent.

9.3.1 The horizontal length of a connector to a natural draft chimney or vent serving a single appliance shall be in accordance with one of the following:

(1) Not more than 50 percent of the height of the vertical portion of the chimney above the connector for a connector serving a solid fuel–burning appliance
(2) Not in excess of the design specifications for a connector that is part of an engineered venting system
(3)* In accordance with NFPA 54 for Category I or draft hood–equipped gas appliances
(4) Not more than 75 percent of the height of the vertical portion of the chimney or vent above the connector for all other fuels

9.3.2 The horizontal length, design, and construction of combined connectors or connectors to a manifold joining two or more appliances to a chimney or vent shall be determined in accordance with approved engineering methods.

9.4 Size.

9.4.1 The connector shall be sized for its entire length in accordance with 9.4.2 and 9.4.3.

9.4.2 The effective area of a connector for a single appliance shall be not less than the area of the appliance flue collar, unless it is part of an engineered venting system.

9.4.3 A connector or manifold serving two or more appliances shall have an effective area equivalent to the combined areas of the appliance flue collars or individual connectors, unless it is part of an engineered venting system.

9.5 Clearance.

9.5.1 Clearances from connectors to combustible material shall be in accordance with the requirements of 9.5.1.1 through 9.5.5.3 for both unprotected and protected installations.

9.5.1.1 Clearances from connectors to unprotected combustible material shall be in accordance with Table 9.5.1.1 and Figure 9.5.1.1.

9.5.1.2 Clearances from connectors to combustible material shall be permitted to be reduced, provided the combustible material is protected by an engineered protection system acceptable to the AHJ, using materials or products listed for protection purposes, or is in accordance with Table 9.5.1.2 and Figure 9.5.1.1 chimney or vent connectors.

9.5.1.2.1 Where the required clearance with no protection is 18 in. (457 mm), clearances shall be permitted to be reduced to the distances in the Minimum Clearance column of Table 9.5.1.2.

9.5.1.2.2 For other required clearances, calculate the allowable clearance from the Maximum Allowable Reduction in Clearance column of Table 9.5.1.2.

9.5.1.2.3 Spacers and ties shall meet the following criteria:

(1) Spacers and ties shall be of noncombustible material.
(2) No spacers or ties shall be used directly behind an appliance or a connector.

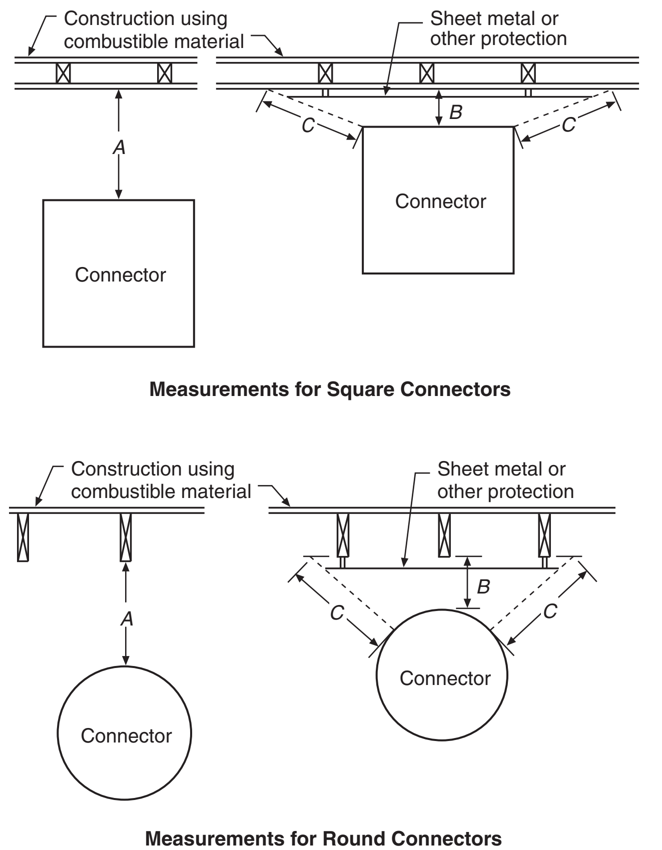
9.5.1.2.4 Mineral wool batts (blanket or board) shall have a minimum density of 8 lb/ft^3 (128 kg/m^3) and have a minimum melting point of 1500°F (816°C).

9.5.1.2.5 Insulation material used as part of a clearance reduction system shall have a thermal conductivity of 1.0 Btu-in./hr-ft^2-°F (0.14 W/m-K) or less. Insulation board shall be formed of noncombustible material.

Table 9.5.1.1 Chimney Connector and Vent Connector Clearances from Combustible Materials

Description of Appliance	Minimum Clearance[a] in.	Minimum Clearance[a] mm
Residential-Type Appliances		
Single-Wall Metal Pipe Connectors		
Gas appliances without draft hoods	18	457
Electric, gas, and oil incinerators	18	457
Oil and solid-fuel appliances	18	457
Unlisted gas appliances with draft hoods	9	229
Boilers and furnaces equipped with listed gas burners and with draft hoods	9	229
Oil appliances listed as suitable for use with Type L vents	9	229
Listed gas appliances with draft hoods and other Category I gas appliances listed for use with Type B vents[c]	6	152
Type L Vent Piping Connectors		
Gas appliances without draft hoods	9	229
Electric, gas, and oil incinerators	9	229
Oil and solid-fuel appliances	9	229
Unlisted gas appliances with draft hoods	6	152
Boilers and furnaces equipped with listed gas burners and with draft hoods	6	152
Oil appliances listed as suitable for use with Type L vents[b]		
Listed gas appliances with draft hoods and other Category I gas appliances listed for use with Type B vents[c]		
Type B Gas Vent Piping Connectors		
Listed gas appliances with draft hoods and other Category I gas appliances listed for use with Type B vents[c]		
Low-Heat Appliances		
Single-Wall Metal Pipe Connectors		
Gas, oil, and solid-fuel boilers, furnaces, and water heaters	18	457
Restaurant-type ranges	18	457
Oil unit heaters	18	457
Unlisted gas unit heaters	18	457
Listed gas unit heaters with draft hoods	6	152
Other low-heat nonresidential appliances	18	457
Medium-Heat Appliances		
Single-Wall Metal Pipe Connectors		
All gas, oil, and solid-fuel appliances	36	914
High-Heat Appliances		
Masonry or Metal Connectors		
All gas, oil, and solid-fuel appliances[d]		

[a]If the listing of an appliance specifies a different clearance, the listed clearance takes precedence.
[b]If listed Type L vent piping is used, the clearance is permitted to be in accordance with the vent listing.
[c] If listed Type B or Type L vent piping is used, the clearance is permitted to be in accordance with the appliance and vent listing.
[d]See 9.5.1.2.



Notes:
(1) *A* equals the required clearance with no protection.
(2) *B* equals the reduced clearance permitted.
(3) The protection applied to the construction using combustible material shall extend far enough in each direction to make *C* equal to *A*.

FIGURE 9.5.1.1 Extent of Protection Required to Reduce Clearances from Chimney or Vent Connectors.

9.5.1.2.6 If a single-wall connector passes through a masonry wall used as a wall shield, there shall be at least ½ in. (12.7 mm) of open, ventilated air space between the connector and the masonry.

9.5.1.2.7 There shall be at least 1 in. (25 mm) between the connector and the protector.

9.5.1.2.8 In no case shall the clearance between the connector and the wall surface be reduced below that allowed in Table 9.5.1.2.

9.5.2* Engineered systems installed for the protection of combustible materials shall reduce the temperature rise of such materials to 90°F (50°C) above ambient.

9.5.3 The following shall apply to clearance protection material:

(1) All clearances shall be measured from the outer surface of the connector to the combustible material, disregarding any intervening protection applied to the combustible material.
(2) The clearance protection material shall not interfere with the accessibility of the connector.

Table 9.5.1.2 Reduction of Connector Clearance with Specified Forms of Protection

Clearance Reduction Applied to and Covering All Combustible Surfaces Within the Distance Specified as Required Clearance with No Protection*	Maximum Allowable Reduction in Clearance (%)		Minimum Clearance			
			As Wall Protector		As Ceiling Protector	
	As Wall Protector	As Ceiling Protector	in.	mm	in.	mm
3½ in. (90 mm) thick masonry wall without ventilated air space	33	—	12	305	—	—
½ in. (12.7 mm) thick noncombustible insulation board over 1 in. (25 mm) glass fiber or mineral wool batts without ventilated air space	50	33	9	229	12	305
0.024 in. (0.61 mm), 24 gauge sheet metal over 1 in. (25 mm) glass fiber or mineral wool batts reinforced with wire, or equivalent, on rear face with ventilated air space	66	50	6	152	9	229
3½ in. (90 mm) thick masonry wall with ventilated air space	66	—	6	152	—	—
0.024 in. (0.61 mm), 24 gauge sheet metal with ventilated air space	66	50	6	152	9	229
½ in. (12.7 mm) thick noncombustible insulation board with ventilated air space	66	50	6	152	9	229
0.024 in. (0.61 mm), 24 gauge sheet metal with ventilated air space over 0.024 in. (0.61 mm), 24 gauge sheet metal with ventilated air space	66	50	6	152	9	229
1 in. (25 mm) glass fiber or mineral wool batts sandwiched between two sheets 0.024 in. (0.61 mm), 24 gauge sheet metal with ventilated air space	66	50	6	152	9	229

Notes:
(1) All clearances and thicknesses are minimum; larger clearances and thicknesses may be permitted.
(2) To calculate the minimum allowable clearance, the following formula can be used: $C_{pr} = C_{un}\ (1 - R/100)$, where C_{pr} is the minimum allowable clearance, C_{un} is the required clearance with no protection, and R is the maximum allowable reduction in clearance.
*See 9.5.1 and Table 9.5.1.1.

9.5.4 Materials and products listed for the purpose of reducing clearance to combustibles shall be installed in accordance with the conditions of the listings and the manufacturers' instructions.

9.5.5 For clearance reduction systems using an air space between the combustible wall and the wall protector, air circulation shall be provided by one of the methods specified in 9.5.5.1 through 9.5.5.3.

9.5.5.1 Air circulation shall be provided by leaving all edges of the wall protector open with at least a 1 in. (25 mm) air gap.

9.5.5.2 Where wall protectors are installed on a single flat wall away from corners, air circulation shall be provided by leaving only the bottom and top edges or only the side and top edges open with at least a 1 in. (25 mm) air gap.

9.5.5.3 Wall protectors that cover two walls in a corner shall be open at the bottom and top edges with at least a 1 in. (25 mm) air gap.

9.6 Location. Where the connector used for a gas appliance having a draft hood or for Category I appliances is located in or passes through an attic, crawl space, or other cold area, that portion of the connector shall be one of the following:

(1) Listed Type B or Type L vent material
(2) Listed vent connector material having at least an equivalent insulating value

9.7 Installation.

9.7.1 The following criteria shall apply to a connector to a masonry chimney:

(1) It shall extend through the wall to the inner face or liner but not beyond.
(2) It shall be firmly cemented to masonry.
(3) If a thimble is used to facilitate removal of the chimney connector for cleaning, the thimble shall be permanently cemented in place with high-temperature cement.

9.7.2 A chimney connector or vent connector shall not pass through any floor or ceiling or through a fire wall or fire partition.

9.7.3 Connectors for listed gas appliances with draft hoods, other listed Category I gas appliances (Table 5.2.3.2, Column I), and oil appliances listed for Type L vents (Table 5.2.3.2, Column III) shall be permitted to pass through walls or partitions constructed of combustible material, provided one of the following conditions is met:

(1) They are made of listed Type B or Type L vent material for gas appliances or of listed Type L vent material for oil

appliances and are installed with not less than listed clearances to combustible material.
(2) They are made of single-wall metal pipe and guarded by a ventilated metal thimble not less than 4 in. (102 mm) larger in diameter than the vent connector.

9.7.4 Connectors for residential-type appliances (Table 5.2.2.1, Column I) shall be permitted to pass through walls or partitions constructed of combustible material if one of the following is true of the connector:

(1) It is listed for wall pass-through and is installed in accordance with the conditions of the listing.
(2) It is incorporated into the chimney construction in accordance with 7.1.2.9.
(3) It is installed in accordance with one of the methods described in Figure 9.7.4.

9.7.5 A connector for a medium- or high-heat appliance (Table 5.2.2.1, Columns IV and V) shall not pass through walls or partitions constructed of combustible material.

9.7.6 Connectors shall maintain a pitch or rise of at least $\frac{1}{4}$ in./ft (6.4 mm/305 mm) of horizontal length of pipe from the appliance to the chimney.

9.7.7 Connectors shall be installed without sharp turns or other construction features that would create excessive resistance to the flow of flue gases.

9.7.8* The following shall apply to a device, other than a damper, that obstructs the free flow of flue gas:

(1) It shall not be installed in a connector, chimney, or vent unless listed for such use. *(For requirements regarding dampers, see Section 9.9.)*
(2) Approved economizers, heat reclaimers, and recuperators shall be permitted in venting systems of equipment that are not required to be equipped with draft hoods in accordance with the fuel-burning appliance listing, provided performance is in accordance with Section 4.1.

9.7.9 Connectors shall be supported and joints fastened using sheet metal screws, rivets, or other approved means.

9.7.10 The entire length of a connector shall be accessible for inspection, cleaning, and replacement.

9.7.11 A connector serving a gas or oil appliance shall not be connected to a chimney flue serving a factory-built fireplace unless specifically listed for such installation.

9.7.12 The following shall apply to gas or oil appliances:

(1) A connector serving a gas or oil appliance shall be permitted to be connected to a masonry fireplace flue if one of the following conditions is met:
    (a) The fireplace opening is sealed.
    (b) The fireplace is abandoned and the chimney flue that vents the fireplace is permanently sealed below the connection.
(2) Listed gas or oil appliances shall be installed in accordance with the listing.

9.7.13 The following shall apply to vent and chimney connectors:

(1) They shall not be covered with insulation.
(2) Listed insulated vent and chimney connectors shall be installed in accordance with the terms of their listing.

9.8 Interconnection.

9.8.1 Connectors serving appliances operating under natural draft shall not be connected into any portion of a mechanical draft system operating under positive pressure.

9.8.2 Unless listed for such connection, solid fuel–burning appliances shall not be connected to a chimney flue serving another appliance.

9.8.3 Gas appliances and appliances burning liquid fuel shall be permitted to be connected to one chimney flue through separate openings or to be connected through a single opening, provided they are joined by a suitable fitting located as close as practicable to the chimney and provided both of the following apply:

(1) Sufficient draft is available for the safe combustion of each appliance and for the removal of all products of combustion.
(2) The appliances so connected are equipped with primary safety controls and all appliances are located in the same room.

9.8.4 If two or more openings are provided into one chimney flue, the following stipulations shall apply:

(1) They shall be at different levels.
(2) The smaller connector shall enter at the highest level consistent with available head room or clearance to combustible material.

9.9 Dampers.

9.9.1 Manually operated dampers shall not be placed in chimneys, vents, or connectors of stoker-fired, liquid fuel–burning, or gas-burning appliances.

9.9.2 Fixed baffles on the appliance side of draft hoods and draft regulators shall not be classified as dampers.

9.9.3 Manually operated dampers shall be permitted to be installed in the chimney connector of hand-fired solid fuel–burning appliances, provided such dampers do not obstruct more than 80 percent of the connector area.

9.9.4 Automatically operated dampers shall meet the following criteria:

(1) They shall be listed.
(2) They shall be installed by a qualified installer in accordance with the terms of the damper and appliance listings.

9.9.5 The installation of dampers on gas appliances shall be in accordance with NFPA 54.

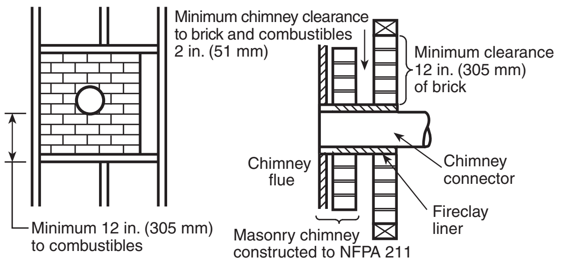
9.10 Draft Hoods. See NFPA 54.

9.11* Draft Regulators.

9.11.1 Gas appliances connected to chimneys, other than those required to be installed with draft hoods by NFPA 54 shall be permitted to be installed with draft regulators in accordance with the appliance manufacturer's instructions.

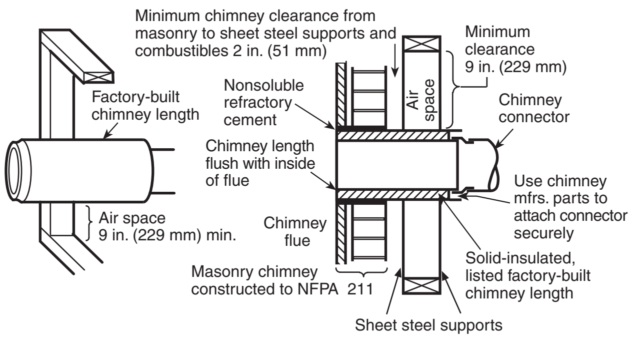
9.11.2 The following shall apply to solid fuel–burning appliances:

(1) They shall be permitted to be installed with draft regulators.
(2) The draft regulators shall be installed and set in accordance with the instructions furnished with the appliance or the draft regulator.



System A. Minimum 3.5 in. (90 mm) thick brick masonry wall framed into combustible wall with a minimum of 12 in. (305 mm) brick separation from clay liner to combustibles. Fireclay liner (ASTM C 315, *Standard Specification for Clay Flue Liners and Chimney Pots*, or equivalent), minimum ⅝ in. (16 mm) wall thickness, shall run from outer surface of brick wall to, but not beyond, the inner surface of chimney flue liner and shall be firmly cemented in place.

Clearance: 12 in. (305 mm)

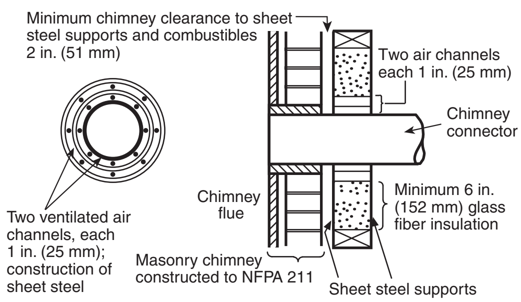


System B. Solid-insulated, listed factory-built chimney length of the same inside diameter as the chimney connector and having 1 in. (25 mm) or more of insulation with a minimum 9 in. (229 mm) air space between the outer wall of the chimney length and combustibles.

The inner end of the chimney length shall be flush with the inside of the masonry chimney flue and shall be sealed to the flue and to the brick masonry penetration with non-water-soluble refractory cement. Supports shall be securely fastened to wall surfaces on all sides.

Fasteners between supports and the chimney length shall not penetrate the chimney liner.

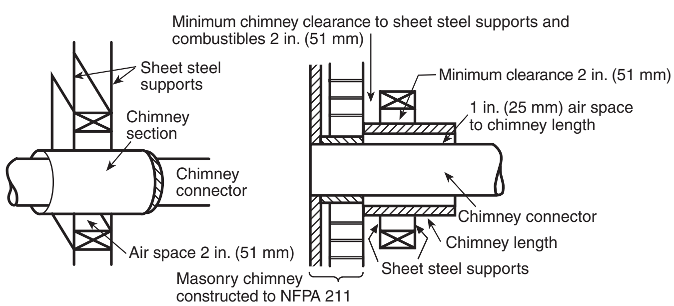
Clearance: 9 in. (229 mm)



System C. Sheet steel chimney connector, minimum 24 gauge [0.024 in. (0.61 mm)] in thickness, with a ventilated thimble, minimum 24 gauge [0.024 in. (0.61 mm)] in thickness, having two 1 in. (25 mm) air channels, separated from combustibles by a minimum of 6 in. (152 mm) of glass fiber insulation. Opening shall be covered, and thimble supported with a sheet steel support, minimum 24 gauge [0.024 in. (0.61 mm)] in thickness.

Supports shall be securely fastened to wall surfaces on all sides and shall be sized to fit and hold chimney section. Fasteners used to secure chimney section shall not penetrate chimney flue liner.

Clearance: 6 in. (152 mm)



System D. Solid-insulated, listed factory-built chimney length with an inside diameter 2 in. (51 mm) larger than the chimney connector and having 1 in. (25 mm) or more of insulation, serving as a pass-through for a single wall sheet steel chimney connector of minimum 24 gauge [0.024 in. (0.61 mm)] thickness, with a minimum 2 in. (51 mm) air space between the outer wall of chimney section and combustibles.

Minimum length of chimney section shall be 12 in. (305 mm). Chimney section concentric with and spaced 1 in. (25 mm) away from connector by means of sheet steel support plates on both ends of chimney section. Opening shall be covered, and chimney section supported on both sides with sheet steel supports of minimum 24 gauge [0.024 in. (0.61 mm)] thickness.

Supports shall be securely fastened to wall surfaces on all sides and shall be sized to fit and hold chimney section. Fasteners used to secure chimney section shall not penetrate chimney flue liner.

Clearance: 2 in. (51 mm)

Note: All clearances and thicknesses are minimums; larger clearances and thicknesses are permitted.

FIGURE 9.7.4 Chimney Connector Systems and Clearances from Combustible Walls for Residential Heating Appliances.

9.11.3 A barometric draft regulator, if used, shall be installed in the same room or enclosure as the appliance in such a manner that no difference in pressure between the air in the vicinity of the regulator and the combustion air supply will be permitted.

Chapter 10 Vents

10.1 Types and Uses. See 5.2.3.2.

10.1.1 Type B gas vents shall be used to vent only listed gas appliances with draft hoods and other Category I gas appliances listed for use with Type B gas vents.

10.1.2 Type B gas vents shall not be used for venting the following:

(1) Vented wall furnaces listed for use with Type BW gas vents only
(2) Incinerators
(3) Appliances that can be converted readily to the use of solid or liquid fuels
(4) Combination gas/oil-burning appliances
(5) Appliances listed for use with chimneys only
(6) Listed Categories II, III, and IV gas appliances

10.1.3 Type BW vents shall be used only with listed vented gas wall furnaces having a capacity not greater than that of the listed Type BW gas vent.

10.1.4* A Special Gas Vent shall be listed and used in accordance with the terms of its listing and the appliance and vent manufacturers' instructions.

10.1.5 Type L vents shall be used only with appliances listed as suitable for such use and with gas appliances listed as suitable for use with Type B gas vents.

10.1.6 Single-wall metal pipe other than Special Gas Vents used to vent Categories II, III, and IV gas appliances shall conform to the requirements of 10.1.6.1 through 10.1.6.4.

10.1.6.1 Single-wall metal pipe shall not be used to vent incinerators.

10.1.6.2 The pipe shall be of sheet copper with a thickness not less than 24 B & S gauge [0.0201 in. (0.51 mm)] or of galvanized steel with a thickness not less than 20 gauge [0.036 in. (0.914 mm)].

10.1.6.3 Single-wall metal pipe shall be used only for runs directly from the space in which the appliance is located, through the roof or exterior wall to the outer air.

10.1.6.4 Single-wall metal pipe shall not originate in any unoccupied attic or concealed space and shall not pass through any attic, inside wall, concealed space, floor, or ceiling.

10.2 Size.

10.2.1 General. Vents shall be sized and configured in accordance with approved methods and the appliance and vent manufacturers' instructions.

10.2.2 Gas Vents. Gas vents shall be sized in accordance with NFPA 54 or other approved methods, and the appliance and vent manufacturers' instructions.

10.3 Location. Single-wall outside vents for appliances used in cold climates shall not be permitted.

10.4 Termination (Height).

10.4.1 All vents shall terminate above the roof surface.

Exception: Pellet vents and other vents as provided in 10.4.5 and Section 10.7.

10.4.1.1 Vents installed with mechanical exhausters shall terminate not less than 12 in. (305 mm) above the highest point where they pass through the roof surface.

10.4.1.2 Vents installed with a listed cap shall terminate in accordance with the terms of the cap's listing.

10.4.1.3 Vents installed without listed caps or mechanical exhausters shall extend 2 ft (0.61 m) above the highest point where they pass through the roof surface of a building and at least 2 ft (0.61 m) higher than any portion of a building within 10 ft (3.1 m). *[See Figure 4.2(a).]*

10.4.2 Natural draft vents for gas appliances shall terminate at an elevation not less than 5 ft (1.52 m) above the highest connected appliance outlet.

Exception: As provided in 10.4.3 and 10.7.2.

10.4.3 Natural draft gas vents serving vented wall furnaces shall terminate at an elevation not less than 12 ft (3.7 m) above the bottom of the furnace.

10.4.4 Vents passing through roofs shall extend through the roof flashing.

10.4.5 Mechanical draft systems shall not be required to comply with 10.4.1 and 10.4.3, provided they comply with the following:

(1) The exit terminal of a mechanical draft system other than a gas-, oil-, or pellet-fired direct vent appliance shall be located in accordance with the following:
    (a) Not less than 3 ft (0.92 m) above any forced air inlet located within 10 ft (3.1 m)
    (b) Not less than 4 ft (1.2 m) below, 4 ft (1.2 m) horizontally from, or 1 ft (305 mm) above any door, window, or gravity air inlet into any building
    (c) Not less than 2 ft (0.61 m) from an adjacent building and not less than 7 ft (2.1 m) above grade where located adjacent to public walkways
(2) The exit terminal shall be arranged such that flue gases are not directed so they jeopardize people, overheat combustible structures, or enter buildings.
(3) Forced draft systems and all portions of induced draft systems under positive pressure during operation shall be designed and installed to be gastight or to prevent leakage of combustion products into a building.
(4) Through-the-wall vents for gas appliances shall not terminate over public walkways or over an area where condensate or vapor could create a nuisance or hazard or could be detrimental to the operation of regulators, relief valves, or other equipment.

10.4.6 Unlisted decorative shrouds shall not be permitted at the termination of a listed Type B gas vent.

10.5 Notice of Usage.

10.5.1 In those localities where solid and liquid fuels are used, gas vents shall be plainly and permanently identified by a label attached to the wall or ceiling at a point where the vent connector enters the gas vent. The label shall read as follows:

"This Gas Vent Is for Appliances That Burn Gas. Do Not Connect to Solid or Liquid Fuel–Burning Appliances or Incinerators."

10.5.2 Where a Type B gas vent, Special Gas Vent, or pellet vent is used as the liner for a masonry chimney, the chimney shall be plainly and permanently identified by a label attached to the wall or ceiling adjacent to the point where the connector enters the chimney and that reads as follows:

"This Chimney Liner Is for [*type, category of appliance*] Appliances That Burn [*type of fuel*] Only. Do Not Connect Other Types of Appliances."

10.6* Installation.

10.6.1 Type B, Type BW, and Type L vents shall be listed and installed in full compliance with the terms of their listing and the manufacturers' installation instructions.

10.6.2 Vents installed through insulation or areas to be insulated shall be separated by a physical barrier to establish and maintain the minimum air space clearance required by the vent manufacturer.

10.6.3 Vents that pass through the floors of buildings requiring the protection of vertical openings shall be enclosed within an approved enclosure.

10.6.3.1 The enclosure walls shall have a fire resistance rating of not less than 1 hour where a vent as described in 10.6.3 is located in a building less than four stories in height.

10.6.3.2 The enclosure walls shall have a fire resistance rating of not less than 2 hours where a vent as described in 10.6.3 is located in a building four or more stories in height.

10.6.4 Unlisted single-wall metal pipe shall be installed as specified in 10.6.4.1 through 10.6.4.3.

10.6.4.1 Unlisted single-wall metal pipe shall be installed with minimum clearances from combustible material as follows:

(1) Unlisted gas appliances without draft hoods — 18 in. (457 mm)
(2) Unlisted gas appliances equipped with draft hoods — 9 in. (229 mm)
(3) Boilers and furnaces equipped with listed conversion gas burners and with draft hoods — 9 in. (229 mm)
(4) Listed gas appliances with draft hoods and other Category I gas appliances listed for use with Type B vents — 6 in. (152 mm)

Exception: Residential incinerators.

10.6.4.2 Where a single-wall metal pipe passes through an exterior wall constructed of combustible material, it shall be guarded at the point of passage by a ventilating metal thimble not smaller than the following:

(1) For listed gas-burning appliances with draft hoods and other Category I gas appliances listed for use with Type B vents, the thimble shall be 4 in. (102 mm) larger in diameter than the pipe.
(2) For unlisted gas-burning appliances with draft hoods, the thimble shall be 6 in. (152 mm) larger in diameter than the pipe.
(3) For unlisted gas appliances without draft hoods, the thimble shall be 12 in. (305 mm) larger in diameter than the pipe.

10.6.4.2.1 The requirement of 10.6.4.2 shall not apply where all combustible material in the wall is cut away from the pipe a sufficient distance to provide the clearance required by 10.6.4.1 from such pipe to combustible material, with entirely noncombustible material used to close such an opening.

10.6.4.2.2 The requirement of 10.6.4.2(1) shall not apply to residential incinerators.

10.6.4.2.3 Where there is a run of not less than 6 ft (1.8 m) of pipe in the opening between the draft hood outlet or flue collar and the thimble, the thimble required by 10.6.4.2(1) shall be permitted to be 2 in. (51 mm) larger in diameter than the pipe.

10.6.4.3 Where an unlisted single-wall metal pipe passes through a roof constructed of combustible material, it shall be guarded at the point of passage according to one of the following:

(1) As specified for passage through a combustible exterior wall by 10.6.4.2
(2) With listed gas appliances that can be connected to Type B gas vents by a noncombustible, nonventilating thimble not less than 4 in. (102 mm) larger in diameter than the vent pipe and extending not less than 18 in. (457 mm) above and 6 in. (152 mm) below the roof with the annular space open at the bottom and closed only at the top

10.7 Special Venting Arrangements.

10.7.1 Direct Vent Appliances Fired with Gas, Oil, or Pellet Fuels.

10.7.1.1 Direct vent appliances shall be listed and installed in accordance with their listing and the manufacturer's instructions.

10.7.1.2 The vent terminal of a direct vent appliance with an input of 10,000 Btu/hr (2930 W) or less shall be located at least 6 in. (152 mm) from any opening into a building, and such an appliance with an input of over 10,000 Btu/hr (2930 W) but not over 50,000 Btu/hr (14,650 W) shall be located not less than 9 in. (229 mm) from any opening through which vent gases could enter a building, and the vent terminal of such appliance having an input over 50,000 Btu/hr (14,650 W) shall be located not less than 12 in. (305 mm) from the opening.

10.7.1.3 The bottom of the vent terminal and the air intake shall be located at least 12 in. (305 mm) above grade.

10.7.2 Ventilating Hoods and Exhaust Systems.

10.7.2.1* Where ventilating hoods and exhaust systems serving commercial cooking appliances are used to vent gas-burning appliances installed in commercial applications, the connector from the appliance shall terminate under the hood not less than 18 in. (457 mm) from any grease filter or screen installed in the hood.

10.7.2.2 Where automatically operated appliances, such as water heaters, are vented through natural draft ventilating hoods, dampers shall not be installed in the ventilating system.

10.7.2.3 Where automatically operated appliances, such as water heaters, are vented through a ventilating hood or exhaust system equipped with a mechanical exhaust system, the appliance control system shall be interlocked to allow appliance operation only when the mechanical exhaust system is in operation. *[See 10.4.5(3).]*

10.7.2.4 A ventilating hood shall be installed above an open-top broiler in a residence.

10.7.2.4.1 The hood shall be made with tight joints and shall be constructed of copper with a thickness not less than 24 B & S gauge [0.0201 in (0.51 mm)] or of galvanized steel with a thickness not less than 28 gauge [0.016 in. (0.406 mm)].

10.7.2.4.2 A clearance of not less than ¼ in. (6.4 mm) between the hood and the underside of combustible material or metal cabinets shall be provided.

10.7.2.4.3 The vertical clearance above the broiler to the underside of combustible material or a metal cabinet protected by the hood shall be not less than 24 in. (610 mm).

10.7.2.4.4 The width and breadth of the hood shall be not less than that of the open-top broiler unit.

10.7.2.4.5 The hood shall be centered over the unit.

10.7.2.4.6 The hood shall be exhausted directly through an outside wall to the outside or connected to a suitable chimney flue used for no other purpose. The connecting duct shall conform to the following:

(1) Connecting ducts shall be made of galvanized steel not less than 28 gauge [0.016 in. (0.406 mm)].
(2) A clearance of not less than 6 in. (152 mm) shall be provided between the exhaust duct and unprotected combustible material.

Exception: This clearance shall be permitted to be reduced where the combustible material is protected in accordance with Table 9.5.1.2.

10.7.3 Clothes Dryers.

10.7.3.1 All ducts expelling lint shall be provided with a lint collector.

10.7.3.2 Requirements for gas-fired clothes dryer exhaust shall be in accordance with NFPA 54.

10.7.3.3 All clothes dryers shall be exhausted to the outside air.

10.7.3.4 Maximum Run. Clothes dryer exhaust ducts shall have a maximum length not exceeding 35 ft (10.7 m) as measured from the dryer terminal to the outlet.

10.7.3.4.1 Reductions of 2½ ft (0.76 m) shall be made in the maximum length of the duct for each 45-degree bend and 5 ft (1.5 m) in the maximum length of the duct for each 90-degree bend.

10.7.3.4.2 The transition duct shall not be included in the maximum length of the duct.

10.7.3.4.3 Where the dryer manufacturer's installation instructions regarding maximum length of exhaust ducts is different from the maximum length specified in 10.7.3.4, the exhaust duct shall be installed in accordance with the dryer manufacturer's installation instructions.

10.7.3.5 A clothes dryer exhaust duct shall not be connected into any chimney connector, vent connector, chimney, or vent.

10.7.3.6 Ducts for exhausting clothes dryers shall not be put together with sheet metal screws or other fastening means that extend into the duct.

10.7.3.7 Supporting Dryer Exhaust Ducts. Dryer exhausts shall be supported with metal straps where additional support is needed.

10.7.3.8 Exhaust ducts for clothes dryers shall meet the following criteria:

(1) They shall be constructed of rigid sheet metal or other noncombustible material and shall have a smooth interior surface.
(2) They shall have a minimum thickness equivalent to No. 24 galvanized steel gauge [0.024 in. (0.61 mm)] for Type 2 ducts and No. 28 gauge [0.016 in. (0.406 mm)] for Type 1 ducts.

10.7.3.9 Electrical wires shall maintain a minimum 1 in. (25 mm) clearance from exhaust ducts for Type 1 clothes dryers.

10.7.3.10 Transition ducts used to connect the dryer to the exhaust duct shall be listed for that application or installed in accordance with the clothes dryer manufacturer's installation instructions.

10.7.3.11 Exhaust ducts for Type 2 clothes dryers shall have a clearance of at least 6 in. (152 mm) to combustible material.

10.7.3.11.1 If such a duct passes through a wall, floor, or partition constructed of combustible material, all such material in the wall, floor, or partition shall be cut away from the duct to provide a clearance of at least 6 in. (152 mm), and the opening shall be closed in accordance with 10.7.3.12.

10.7.3.11.2 Exhaust ducts for Type 2 clothes dryers shall be permitted to be installed with reduced clearances to combustible material, provided the combustible material is protected as described in Table 9.5.1.2.

10.7.3.12 Where ducts pass through walls, floors, or partitions, the space around the duct shall be sealed with noncombustible material.

10.7.3.13 The following shall apply to multiple installations of Type 1 and Type 2 clothes dryers:

(1) The installations shall be made in a manner to prevent adverse operation due to backpressures that might be created in the exhaust.
(2) Common exhaust vents that pass through floors of buildings requiring the protection of vertical openings shall be enclosed with approved walls having a fire resistance rating of not less than the following:
    (a) 1 hour, where such chimneys are located in a building less than four stories in height
    (b) 2 hours, where such chimneys are located in a building four or more stories in height

10.7.4 Appliances with Integral Vents. Gas appliances incorporating integral venting means shall be installed in accordance with the manufacturer's installation instructions and 10.4.5. [**54:**12.3.6]

Chapter 11 Fireplaces

11.1 Factory-Built Fireplaces.

11.1.1 Factory-built fireplaces shall be listed and installed in accordance with the terms of the listing.

11.1.2 Hearth extensions shall be provided in accordance with the manufacturers' instructions or be of masonry on noncombustible construction in accordance with Section 11.3.

11.1.3 Factory-built fireplaces shall be secured to the floor or structural framing of the building in order to prevent shifting.

11.1.4 Only listed decorative shrouds at the termination of a factory-built fireplace chimney shall be permitted.

11.2* Masonry Fireplaces.

11.2.1 Construction.

11.2.1.1 Fireplaces shall be constructed of solid masonry units or of reinforced Portland or refractory cement concrete.

11.2.1.2 Masonry fireplaces shall be supported on foundations of one of the following:

(1) Masonry
(2) Reinforced Portland cement concrete
(3) Refractory cement concrete
(4) Other noncombustible construction having a fire resistance rating of not less than 3 hours, provided such supports are adequate for the load

11.2.1.2.1 Footings for masonry fireplaces and their chimneys shall be constructed of concrete or solid masonry at least 12 in. (305 mm) thick and shall extend at least 6 in. (152 mm) beyond the face of the fireplace or foundation wall on all sides.

11.2.1.2.2 Footings shall be founded on natural undisturbed earth or engineered fill below frost depth.

11.2.1.2.3 In areas not subject to freezing, footings shall be at least 12 in. (305 mm) below finished grade.

11.2.1.3 The firebox of a concrete or masonry fireplace shall have a minimum depth of 20 in. (508 mm).

11.2.1.3.1 The throat shall not be less than 8 in. (203 mm) above the fireplace opening.

11.2.1.3.2 The throat opening shall not be less than 4 in. (102 mm) in depth.

11.2.1.3.3 The cross-sectional area of the passageway above the firebox, including the throat, damper, and smoke chamber, shall not be less than the cross-sectional area of the flue.

11.2.1.3.4 Rumford fireplaces shall be permitted, provided that the depth of the fireplace is at least 12 in. (305 mm) and at least one-third the width of the fireplace opening, and the throat is at least 12 in. (305 mm) above the lintel and at least one-twentieth the cross-sectional area of the fireplace opening.

11.2.1.4 Where a lining of low-duty fireclay brick (ASTM C27, *Standard Classification of Fireclay and High-Alumina Refractory Brick*), firebox brick (ASTM C1261, *Standard Specification for Firebox Brick for Residential Fireplaces*), or the equivalent, at least 2 in. (51 mm) thick laid in medium-duty refractory mortar (ASTM C199, *Standard Test Method for Pier Test for Refractory Mortars*), or the equivalent, or other approved lining is provided, the total thickness of back and sides, including the lining, shall be not less than 8 in. (203 mm).

11.2.1.5 All joints and intersections between the hearth extension/fireplace facing and the fire chamber (firebox) shall be fully sealed with medium-duty refractory mortar (ASTM C199, *Standard Test Method for Pier Test for Refractory Mortars*). Gaps or voids at supporting lintels and joints between steel fireplace units and the fireplace face or between the frames of dampers and the fireplace face shall be sealed with the same material or with a high-temperature [2000°F (1093°C) service rating] insulating mortar.

11.2.1.6 Where the lining described in 11.2.1.4 is not provided, the thickness of the back and sides of the fireplace shall be not less than 12 in. (305 mm).

11.2.1.7 Where the masonry supporting a fireplace is designed to support vertical loads from the building and corbels are used to support beams or girders, corbeling shall be in accordance with 7.1.2 for masonry chimneys.

11.2.1.8 Masonry over a fireplace opening shall be supported by a lintel of noncombustible material.

11.2.1.8.1 The minimum required bearing length on each end of the fireplace opening shall be a nominal 4 in. (102 mm).

11.2.1.8.2 The fireplace throat or damper shall be located a minimum of 8 in. (203 mm) above the top of the fireplace opening.

11.2.1.9 Where a lining of low-duty fireclay brick (ASTM C27, *Standard Classification of Fireclay and High-Alumina Refractory Brick*), firebox brick (ASTM C1261, *Standard Specification for Firebox Brick for Residential Fireplaces*), or the equivalent, at least 2 in. (51 mm) thick laid in medium-duty refractory mortar (ASTM C199, *Standard Test Method for Pier Test for Refractory Mortars*), or the equivalent, or other approved lining is provided, the total thickness of the smoke chamber walls, including the lining, shall be not less than 6 in. (152 mm).

11.2.1.10 Where unlined, the smoke chamber wall thickness shall be not less than 8 in. (203 mm).

11.2.1.11 The smoke chamber height shall not be greater than the inside width of the fireplace room opening.

11.2.1.12 The smoke chamber depth shall not be greater than the depth of the fireplace fire chamber. *(See Figure 11.2.1.12.)*

11.2.1.13 The inner surfaces of the smoke chamber shall be parge coated smooth, with an insulating refractory mortar, and not inclined more than 45 degrees from vertical.

11.2.1.14 Masonry fireplaces shall be provided with chimneys designed and constructed in compliance with one of the following:

(1) In accordance with the requirements for construction of masonry chimneys *(See Section 7.2.)*
(2) Where permitted by the individual listing, with approved factory-built chimneys having approved adapters in accordance with the requirements for factory-built chimneys *(See Chapter 5.)*

11.2.1.15 Hearth Thickness. The minimum thickness of fireplace hearths shall be 4 in. (102 mm).

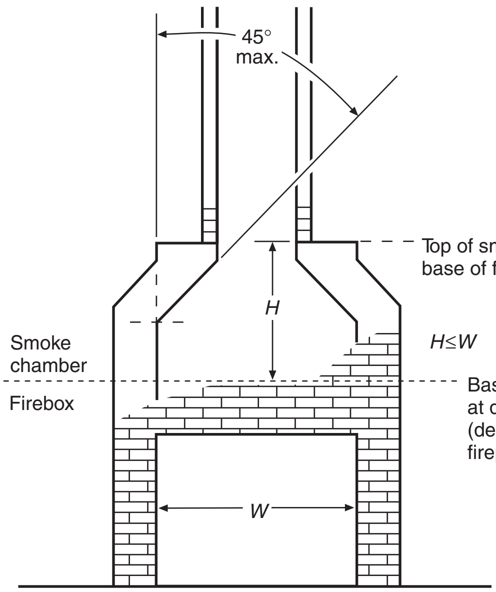


FIGURE 11.2.1.12 Sectional View of Fireplace Showing Smoke Chamber.

11.2.2 Seismic Reinforcing.

11.2.2.1 Reinforcement shall not be required in Seismic Design Category A, B, or C.

11.2.2.2 In structures of Seismic Design Category D, fireplaces with chimneys up to 40 in. (1016 mm) wide, four No. 4 continuous vertical bars, anchored in the foundation, shall be placed in the concrete, between wythes of solid masonry or within the cells of hollow unit masonry and grouted in accordance with ASTM C476, *Standard Specification for Grout for Masonry*.

11.2.2.2.1 For fireplaces with chimneys greater than 40 in. (1016 mm) wide, two additional No. 4 vertical bars shall be provided for each additional 40 in. (1016 mm) in width or fraction thereof.

11.2.2.2.2 Vertical reinforcement shall be placed enclosed within ¼ in. (6.4 mm) ties or other reinforcing of equivalent net cross-sectional area, spaced not to exceed 18 in. (457 mm) on center in concrete, or placed in the bed joints of unit masonry at a minimum of every 18 in. (457 mm) of vertical height.

11.2.2.2.3 Two such ties shall be provided at each bend in the vertical bars.

11.2.2.2.4 In structures of Seismic Design Category E or F, masonry and concrete chimneys shall be reinforced in accordance with the requirements of Sections 43.1 through 43.8 of *NFPA 5000*.

11.2.3 Seismic Anchorage.

11.2.3.1 Seismic anchorage shall not be required in Seismic Design Category A, B, or C.

11.2.3.2 In structures of Seismic Category D, masonry and concrete chimneys shall be anchored at each floor, ceiling, or roof line more than 6 ft (1.8 m) above grade except where constructed completely within the exterior walls.

11.2.3.3 Two 3⁄16 in. by 1 in. (4.8 mm by 25 mm) straps shall be embedded a minimum of 12 in. (305 mm) into the chimney.

11.2.3.3.1 Straps shall be hooked around the outer bars and extend 6 in. (152 mm) beyond the bend.

11.2.3.3.2 Each strap shall be fastened to a minimum of four floor joists with two ½ in. (12.7 mm) bolts.

11.2.4 Steel Fireplace Units.

11.2.4.1 Steel fireplace units incorporating a firebox liner of not less than ¼ in. (6.4 mm) thick steel and an air chamber shall be installed with masonry to provide a total thickness at the back and sides of not less than 8 in. (203 mm), not less than 4 in. (102 mm) of which shall be solid masonry.

11.2.4.2 Listed firebox liners shall be installed in accordance with the terms of the listing.

11.2.4.3 Warm-air ducts employed with steel fireplace units of the circulating air type shall be constructed of metal or masonry.

11.2.5 Clearance.

11.2.5.1 All wood beams, joists, studs, and other combustible material shall have a clearance to masonry fireplaces as follows:

(1) Not less than 2 in. (51 mm) from the front faces and sides
(2) Not less than 4 in. (102 mm) from the back faces of masonry fireplaces *(See Figure 11.2.5.1.)*

11.2.5.2 Spaces between headers or trimmers of combustible material and masonry fireplaces shall be firestopped with one of the following noncombustible materials:

(1) Galvanized steel not less than 26 gauge [0.019 in. (0.483 mm)] in thickness
(2) Noncombustible sheet material not more than ½ in. (12.7 mm) thick

11.2.5.3 Woodwork, such as wood trim, mantels, and other combustible material, shall not be placed within 6 in. (152 mm) of a fireplace opening.

11.2.5.4 Combustible material above and projecting more than 1½ in. (38 mm) from a fireplace opening shall not be placed less than 12 in. (305 mm) from the top of the fireplace opening. *(See Figure 11.2.5.4.)*

11.2.6 Accessibility. For cleaning purposes, means shall be provided for access to the venting area above and immediately behind any movable damper valve plate in masonry fireplaces and steel fireplace units by one of the following methods:

(1) A damper plate that can be removed with common hand tools
(2) A cleanout opening located to provide access to the smoke chamber area

11.2.7 Cleanout Openings. Cleanout openings shall be equipped with ferrous metal, stainless steel, precast cement, or other approved noncombustible doors and frames arranged to remain tightly closed and secured when not in use.

11.2.8 Ash Dumps. Cleanouts, if provided, shall be accessible and located so that ash removal will not create a hazard to combustible materials.

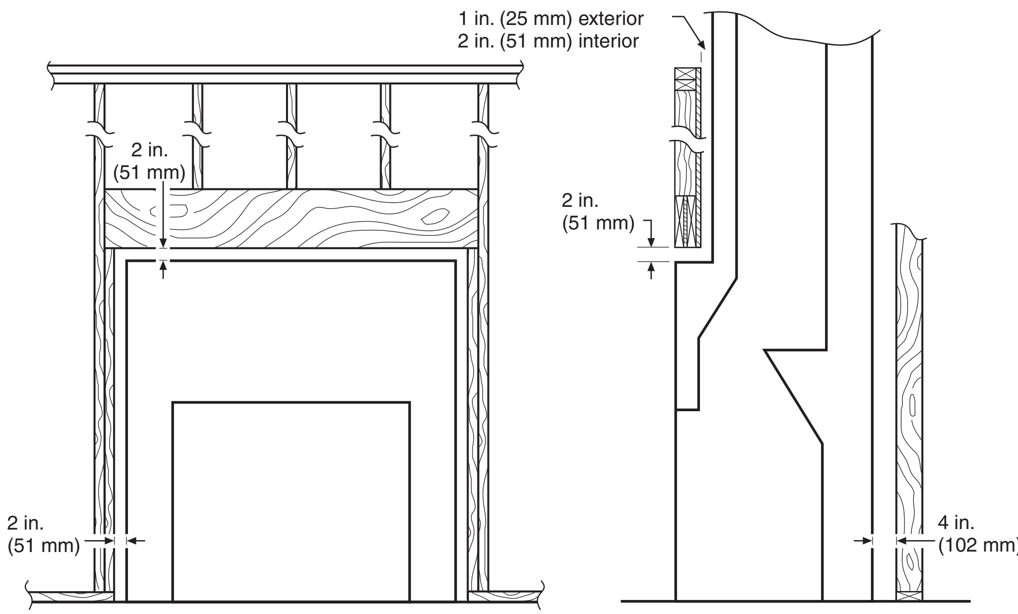

FIGURE 11.2.5.1 Fireplace Clearance to Combustible Material.

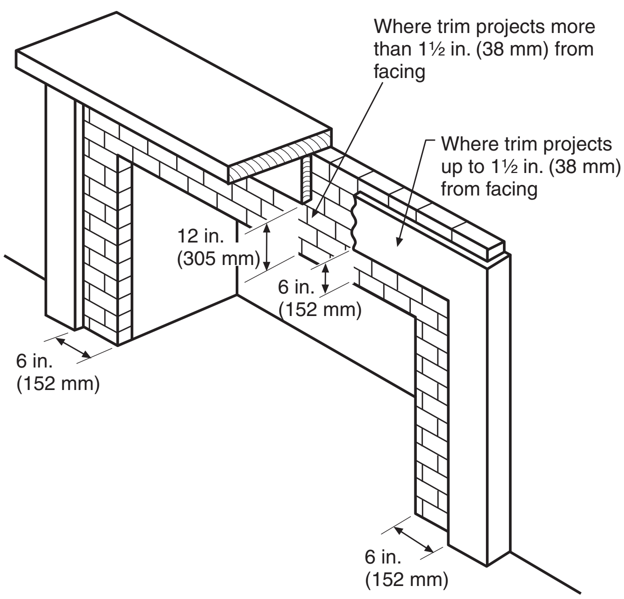

FIGURE 11.2.5.4 Fireplace Clearance to Combustible Material.

11.2.9 Dampers.

11.2.9.1 Masonry fireplaces shall be equipped with a ferrous metal damper located at least 8 in. (203 mm) above the top of the fireplace opening.

11.2.9.2 Dampers shall be installed in the fireplace or at the top of the flue venting the fireplace and shall be operable from the room containing the fireplace.

11.2.9.3 A nonferrous metal damper shall be permitted to be installed at the top of the flue specified in 11.2.9.2.

11.2.9.4 Damper controls shall be permitted to be located in the fireplace.

11.2.10* Masonry Fireplace Accessories. Fireplace accessories shall be one of the following:

(1) Installed by a qualified agency
(2) Listed and installed in accordance with the terms of their listing
(3) Installed in accordance with the accessory manufacturer's installation instructions

11.3 Hearth Extensions.

11.3.1 Masonry fireplaces shall have hearth extensions of brick, concrete, stone, tile, or other approved noncombustible material wholly supported by and integral with the chimney structure, and a minimum 4 in. (102 mm) clearance shall be maintained directly below the underside.

11.3.1.1 Support for the hearth shall be provided by a structural slab or corbeled brickwork.

11.3.1.2 Wooden forms used during the construction of the hearth and hearth extension shall be removed when the construction is completed.

11.3.2 The minimum thickness of the hearth extension shall be 2 in. (51 mm).

11.3.3 Where the fireplace opening is less than 6 ft^2 (0.56 m^2), the hearth extension shall extend as follows:

(1) At least 16 in. (406 mm) in front of the facing material
(2) At least 8 in. (203 mm) beyond each side of the fireplace opening *(See Figure 11.3.3.)*

11.3.4 Where the fireplace opening is 6 ft^2 (0.56 m^2) or larger, the hearth extension shall extend as follows:

(1) At least 20 in. (508 mm) in front of the facing material
(2) At least 12 in. (305 mm) beyond each side of the fireplace opening *(See Figure 11.3.3.)*

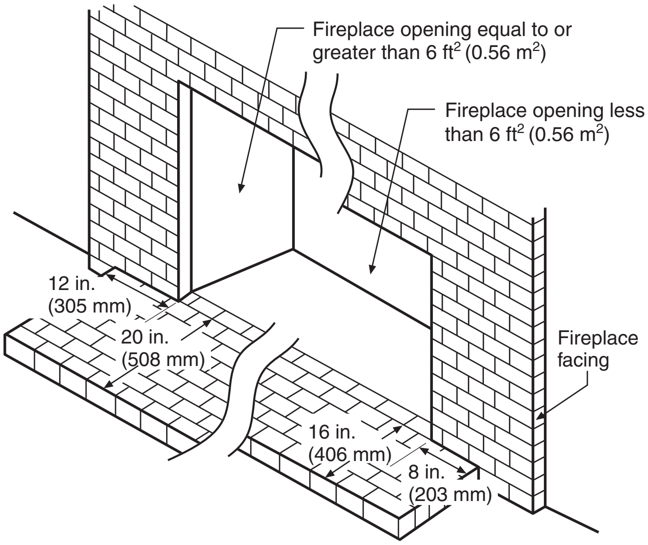

FIGURE 11.3.3 Fireplace Hearth Extension Requirements.

11.3.5 Where a fireplace is elevated above or overhangs a floor, the hearth extension also shall extend over the area under the fireplace.

11.4 Combustion Air Ducts.

11.4.1 Where installed, combustion air ducts shall be installed in accordance with this section.

11.4.1.1 Combustion air ducts for factory-built fireplaces shall be a listed component of the fireplace and installed according to the manufacturer's instructions.

11.4.1.2 Listed combustion air duct systems for masonry fireplaces shall be installed according to the terms of their listing and the manufacturers' instructions.

11.4.2 Combustion air ducts shall extend as directly as practicable from the outdoors (inlet) to a termination outside the fire chamber (outlet).

11.4.3 Combustion air ducts shall be constructed of one of the following:

(1) Masonry
(2) Galvanized steel with a thickness not less than 26 gauge [0.019 in. (0.483 mm)]
(3) Other approved noncombustible material

11.4.4 Combustion air ducts shall be equipped with a damper that is capable of being fully closed.

11.4.5 Combustion air ducts that terminate outside the fire chamber but within 6 in. (152 mm) of the fire chamber shall be designed and installed to prevent the direct entry of flame, embers, or ashes from the fire chamber into the duct.

11.4.6 Unlisted combustion air ducts shall be installed with a minimum 1 in. (25 mm) clearance to combustibles for all parts of the duct construction within 5 ft (1.53 m) of the duct outlet.

11.4.7 The exterior inlet of the combustion air duct shall be screened.

11.4.8 Combustion air ducts shall not originate in any of the following:

(1) Attic
(2) Basement
(3) Garage
(4) Other interior space

Chapter 12 Masonry Heaters

12.1 Listed Masonry Heaters. Listed masonry heaters shall be installed in accordance with the manufacturer's installation instructions.

12.2 Unlisted Masonry Heaters. Unlisted masonry heaters shall be constructed in accordance with ASTM E1602, *Standard Guide for Construction of Solid Fuel Burning Masonry Heaters.*

12.3 Clearances to Combustibles.

12.3.1 Listed masonry heaters shall be installed with clearances according to their listing.

12.3.2 Unlisted masonry heaters shall be installed with clearances in accordance with ASTM E1602, *Standard Guide for Construction of Solid Fuel Burning Masonry Heaters.*

Chapter 13 Solid Fuel–Burning Appliances

13.1 Appliances. Solid fuel–burning appliances shall be one of the following:

(1) Listed and installed in accordance with the terms of their listing and this chapter
(2) Approved by the AHJ

13.1.1 Unlisted appliances approved by the AHJ shall be installed as follows:

(1) In accordance with the manufacturer's instructions
(2) As specified in this chapter

13.1.2 The requirements in 13.1.1 shall not apply to mobile home installations.

13.2 Location of Appliances.

13.2.1* Every appliance shall be located with respect to building construction and other equipment to allow access to the appliance.

13.2.2 Solid fuel–burning appliances shall not be installed in alcoves or enclosed spaces less than 512 ft^3 (14.5 m^3) unless specifically listed for such use.

13.2.2.1 Solid fuel–burning appliances listed for installation in enclosed spaces or alcoves less than 512 ft^3 (14.5 m^3) shall be installed in accordance with the requirements of the listing and the manufacturer's instructions.

13.2.2.2 The space or room shall be sized to allow circulation of heated air.

13.2.2.3 Appliances shall be so located as not to interfere with the circulation of air within the heated space.

13.2.3 Solid fuel–burning appliances shall not be installed in any location where gasoline or any other flammable vapors or gases are present.

13.2.4 Solid fuel–burning appliances shall not be installed in any garage.

13.3 Air for Combustion and Ventilation.

13.3.1 Solid fuel–burning appliances shall be installed in a location and manner so as to provide ventilation and combustion air supply to allow proper combustion of fuel, chimney draft, and maintenance of safe temperatures.

13.3.2 Where buildings are so tight that normal infiltration does not provide the necessary air, outside air shall be introduced.

13.4 Chimney Connections and Usage.

13.4.1 Chimney Connection. All solid fuel–burning appliances shall be connected to chimneys in accordance with Chapter 9.

13.4.1.1 The chimney provided shall be in accordance with Table 5.2.2.1.

13.4.1.2 Galvanized steel pipe shall not be used for solid fuel–burning appliances.

13.4.2 Clearance. The clearance of chimney connectors to combustible material shall be in accordance with Table 9.5.1.1.

13.4.3 Inspection and Cleaning Access. Connectors and chimneys for solid fuel–burning appliances shall be designed, located, and installed to allow access for internal inspection and cleaning.

13.4.4* Flue Cross-Sectional Area. For residential-type, natural draft solid fuel–burning appliances, the flue shall meet the following conditions:

(1) The cross-sectional area of the flue shall not be less than the cross-sectional area of the appliance flue collar, unless specified by the appliance manufacturer.
(2) The cross-sectional area of the flue of a chimney with no walls exposed to the outside below the roofline shall not be more than three times the cross-sectional area of the appliance flue collar.
(3) The cross-sectional area of the flue of a chimney with one or more walls exposed to the outside below the roofline shall not be more than two times the cross-sectional area of the appliance flue collar.

13.4.5 Connection to Masonry Fireplaces.

13.4.5.1 A natural draft solid fuel–burning appliance such as a stove or insert shall be permitted to use a masonry fireplace flue where the following conditions are met:

(1) There is a connector that extends from the appliance to the flue liner.
(2) Any unexposed metal that is used as a connector and is exposed to flue gases is constructed of stainless steel or other equivalent material that resists corrosion, softening, or cracking from flue gases at temperatures up to 1800°F (982°C).
(3) The cross-sectional area of the flue is no smaller than the cross-sectional area of the flue collar of the appliance, unless otherwise specified by the appliance manufacturer.
(4)* The cross-sectional area of the flue of a chimney with no walls exposed to the outside below the roofline is no more than three times the cross-sectional area of the appliance flue collar.
(5) The cross-sectional area of the flue of a chimney with one or more walls exposed to the outside below the roofline is no more than two times the cross-sectional area of the appliance flue collar.
(6) If the appliance vents directly through the chimney wall above the smoke chamber, there is a noncombustible seal below the entry point of the connector.
(7) The installation is such that the chimney system can be inspected and cleaned.
(8) Means are provided to prevent dilution of combustion products in the chimney flue with air from the habitable space.

13.4.5.2 Listed fireplace accessories shall be permitted to use a masonry fireplace flue in accordance with their listing.

13.4.6 Existing Flue Use. Another solid fuel–burning appliance shall not be installed using an existing flue serving a factory-built fireplace unless the appliance is specifically listed for such installation.

13.5 Installation of Residential-Type Appliances

13.5.1 General Requirements.

13.5.1.1 Residential-type solid fuel–burning appliances that are tested and listed by a recognized testing laboratory for installation on floors constructed of combustible materials shall be placed on floors in accordance with the requirements of the listing and the conditions of approval.

13.5.1.2 Appliances that are not listed by a recognized testing laboratory shall be provided with floor protection in accordance with the provisions of 13.5.2 or 13.5.3.

13.5.1.3 Residential-type solid fuel–burning appliances shall be permitted to be placed without floor protection in any of the following manners:

(1) On concrete bases adequately supported on compacted soil, crushed rock, or gravel
(2) On concrete slabs or masonry arches that do not have combustible materials attached to the underside
(3) On approved assemblies constructed of only noncombustible materials and having a fire resistance rating of not less than 2 hours, with floors constructed of noncombustible material
(4) On properly stabilized ground that can support the load of the appliance

13.5.1.4 Any floor assembly, slab, or arch shall extend not less than 18 in. (457 mm) beyond the appliance on all sides.

13.5.1.5 In lieu of the requirements for floor protection specified herein, a floor protector listed by a recognized testing laboratory and installed in accordance with the installation instructions shall be permitted to be employed.

13.5.1.6 Concrete bases, concrete slabs, masonry arches, and floor–ceiling assemblies and their supports shall be designed and constructed to support the appliances.

13.5.2 Room Heaters, Fireplace Stoves, Room Heater/Fireplace Stove Combinations, and Ranges.

13.5.2.1 Room heaters, fireplace stoves, room heater/fireplace stove combinations, or ranges that are set on legs or pedestals that provide not less than 6 in. (152 mm) of ventilated open space beneath the fire chamber or base of the appliance shall be permitted to be placed on floors of combustible construction, provided the following conditions exist:

(1) The floor under the appliance is protected with closely spaced solid masonry units not less than 2 in. (51 mm) in thickness.
(2) The top surface of the masonry is covered with sheet metal not less than 24 gauge [0.024 in. (0.61 mm)].
(3) The floor protection extends not less than 18 in. (457 mm) beyond the appliance on all sides.

13.5.2.2 Room heaters, fireplace stoves, room heater/fireplace stove combinations, or ranges that are set on legs or pedestals providing 2 in. to 6 in. (51 mm to 152 mm) of ventilated open space beneath the fire chamber or base of the appliance shall be permitted to be placed on floors of combustible construction, provided the following conditions exist:

(1) The floor under the appliance is protected with one course of hollow masonry units not less than 4 in. (102 mm) in nominal thickness.
(2) The masonry units are laid with ends unsealed and joints matched in such a way as to provide free circulation of air through the core spaces of the masonry.
(3) The top surface of the masonry is covered with sheet metal not less than 24 gauge [0.024 in. (0.61 mm)].
(4) The floor protection extends not less than 18 in. (457 mm) beyond the appliance on all sides.

13.5.2.3 Room heaters, fireplace stoves, room heater/fireplace stove combinations, or ranges with legs or pedestals that provide less than 2 in. (51 mm) of ventilated open space beneath the fire chamber or base of the appliance shall not be placed on floors of combustible construction.

13.5.3 Furnaces and Boilers.

13.5.3.1 Furnaces or boilers with legs or pedestals that provide not less than 6 in. (152 mm) of ventilated open space beneath the fire chamber or base of the appliance shall be permitted to be placed on floors of combustible construction, provided the floor under the appliance has the following characteristics:

(1) It is protected with one course of hollow masonry units not less than 4 in. (102 mm) in thickness.
(2) The masonry units are laid with ends unsealed and joints matched in such a way as to provide free circulation of air through the core spaces of the masonry.
(3) The top surface of the masonry is covered with a steel plate not less than $\frac{3}{16}$ in. (4.8 mm) in thickness.
(4) The floor protection extends not less than 18 in. (457 mm) beyond the appliance on all sides.

13.5.3.2 Furnaces or boilers that are set on legs or pedestals that provide 2 in. to 6 in. (51 mm to 152 mm) of ventilated open space beneath the fire chamber or base of the appliance shall be permitted to be placed on floors of combustible construction, provided the floor under the appliance has the following characteristics:

(1) It is protected with two courses of hollow masonry units, each not less than 4 in. (102 mm) in thickness.
(2) The masonry units are laid with ends unsealed and joints matched in such a way as to provide free circulation of air through the core spaces of the masonry.
(3) The top surface of the masonry is covered with a steel plate not less than $\frac{3}{16}$ in. (4.8 mm) in thickness.
(4) The floor protection extends not less than 18 in. (457 mm) beyond the appliance on all sides.

13.5.3.3 Furnaces or boilers with legs or pedestals that provide less than 2 in. (51 mm) of ventilated open space beneath the fire chamber or base of the appliance shall not be placed on floors of combustible construction.

13.5.4 Installation of Low-Heat Nonresidential Appliances.

13.5.4.1 Low-heat nonresidential solid fuel–burning appliances that have been tested and listed by a recognized testing laboratory for placement on floors constructed with a combustible material shall be placed on floors in accordance with the requirements of the listing and conditions of approval.

13.5.4.1.1 Appliances that are not listed by a recognized testing laboratory shall be provided with floor protection in accordance with the provisions of 13.5.4.3 or 13.5.4.4.

13.5.4.1.2 Low-heat nonresidential solid fuel–burning appliances shall be permitted to be placed without floor protection in any of the following manners:

(1) On floors constructed of noncombustible materials that have a fire resistance rating of not less than 2 hours and that extend not less than 18 in. (457 mm) beyond the appliance on all sides
(2) On concrete bases adequately supported on compacted soil, crushed rock, or gravel
(3) On properly stabilized ground that can support the load of the appliance

13.5.4.2 Concrete bases, concrete slabs, and floors shall be designed and constructed to support the appliances.

13.5.4.3 Low-heat nonresidential solid fuel–burning appliances that are set on legs or pedestals that provide not less than 18 in. (457 mm) of ventilated open space beneath the fire chamber or base of the appliance shall be permitted to be placed on floors of combustible construction, provided the following conditions exist:

(1) The floor under the appliance is protected with one course of hollow masonry units not less than 4 in. (102 mm) in thickness.
(2) The masonry units are laid with ends unsealed and joints matched in such a way as to provide free circulation of air through the core spaces of the masonry.
(3) The top surface of the masonry is covered with a steel plate not less than $\frac{3}{16}$ in. (4.8 mm) in thickness.
(4) The floor protection extends not less than 18 in. (457 mm) beyond the appliance on all sides.

13.5.4.4 Low-heat nonresidential solid fuel–burning appliances that are set on legs or pedestals that provide 6 in. to 18 in. (152 mm to 457 mm) of ventilated open space beneath the fire chamber or base of the appliance shall be permitted to be placed on floors of combustible construction, provided the following conditions exist:

(1) The floor under the appliance is protected with two courses of hollow masonry units, each not less than 4 in. (102 mm) in thickness.
(2) The masonry units are laid with ends unsealed and joints matched in such a way as to provide free circulation of air through the core spaces of the masonry.
(3) The top surface of the masonry is covered with a steel plate not less than $\frac{3}{16}$ in. (4.8 mm) in thickness.
(4) The floor protection extends not less than 18 in. (457 mm) beyond the appliance on all sides.

13.5.4.5 Low-heat nonresidential solid fuel–burning appliances with legs or pedestals that provide less than 6 in. (152 mm) of ventilated open space beneath the fire chamber or base of the appliance shall not be placed on floors of combustible construction.

13.5.5 Installation of Medium-Heat Nonresidential Appliances.

13.5.5.1 Medium-heat nonresidential solid fuel–burning appliances that have been tested and listed by a recognized testing laboratory for placement on floors constructed with a combustible material shall be placed on floors in accordance with the requirements of the listing and conditions of approval.

13.5.5.1.1 Appliances that are not listed by a recognized testing laboratory shall be provided with floor protection in accordance with the provisions of 13.5.5.3 or 13.5.5.4.

13.5.5.1.2 Medium-heat nonresidential solid fuel–burning appliances shall be permitted to be placed without floor protection in any of the following manners:

(1) On concrete bases adequately supported on compacted soil, crushed rock, or gravel
(2) On floors constructed of noncombustible materials that have a fire resistance rating of not less than 2 hours and that extend not less than 3 ft (0.92 m) beyond the appliance on all sides and 8 ft (2.45 m) beyond the front or side where ashes are removed
(3) On properly stabilized ground that can support the load of the appliance

13.5.5.2 Concrete bases, concrete slabs, and floors shall be designed and constructed to support the appliances.

13.5.5.3 Medium-heat nonresidential solid fuel–burning appliances that are set on legs or pedestals that provide not less than 24 in. (610 mm) of ventilated open space beneath the fire chamber or base of the appliance shall be permitted to be placed on floors of combustible construction, provided the floor under the appliance has the following characteristics:

(1) It is protected with one course of hollow masonry units not less than 4 in. (102 mm) in thickness.
(2) The masonry units are laid with ends unsealed and joints matched in such a way as to provide free circulation of air through the core spaces of the masonry.
(3) The top surface of the masonry is covered with a steel plate not less than $\frac{3}{16}$ in. (4.8 mm) in thickness.
(4) The floor protection extends not less than 3 ft (0.92 m) beyond the appliance on all sides and 8 ft (2.45 m) beyond the front or side where ashes are removed.

13.5.5.4 Medium-heat nonresidential solid fuel–burning appliances that are set on legs or pedestals that provide 18 in. to 24 in. (457 mm to 610 mm) of ventilated open space beneath the fire chamber or base of the appliance shall be permitted to be placed on floors of combustible construction, provided the floor under the appliance has the following characteristics:

(1) It is protected with two courses of hollow masonry units, each not less than 4 in. (102 mm) in thickness.
(2) The masonry units are laid with ends unsealed and joints matched in such a way as to provide free circulation of air through the core spaces of the masonry.
(3) The top surface of the masonry is covered with a steel plate not less than $\frac{3}{16}$ in. (4.8 mm) in thickness.
(4) The floor protection extends not less than 3 ft (0.92 m) beyond the appliance on all sides and 8 ft (2.45 m) beyond the front or side where ashes are removed.

13.5.5.5 Medium-heat nonresidential solid fuel–burning appliances with legs or pedestals that provide less than 18 in. (457 mm) of ventilated open space beneath the fire chamber or base of the appliance shall not be placed on floors of combustible construction.

13.5.6 Installation of High-Heat Nonresidential Appliances.

13.5.6.1 High-heat nonresidential solid fuel–burning appliances shall be placed in one of the following manners:

(1) On concrete bases adequately supported on compacted soil, crushed rock, or gravel
(2) On floors constructed of noncombustible materials that have a fire resistance rating of not less than 2 hours and that extend not less than 10 ft (3.1 m) beyond the appliance on all sides and not less than 30 ft (9.2 m) beyond the front or side where hot products are removed
(3) On properly stabilized ground that can support the load of the appliance

13.5.6.2 Concrete bases and floors shall be designed and constructed to support the appliances.

13.5.6.3 High-heat nonresidential solid fuel–burning appliances shall not be placed on floors of combustible construction.

13.6 Clearances from Solid Fuel–Burning Appliances.

13.6.1 The clearance shall be not less than specified in Table 13.6.1.

13.6.1.1 Appliances listed for installation with clearances less than specified in Table 13.6.1 shall be permitted to be installed in accordance with the terms of their listing and the manufacturer's instructions.

13.6.1.2 Heating furnaces and boilers and water heaters specifically listed for installation in spaces such as alcoves shall be permitted to be so installed in accordance with the terms of their listing, provided the specified clearance is maintained regardless of whether the enclosure is of combustible or noncombustible material.

13.6.1.3 These clearances shall apply to appliances installed in rooms that are large in comparison with the size of the appliances.

13.6.2 Clearance Reduction.

13.6.2.1 Clearances from listed and unlisted solid fuel–burning appliances to combustible material shall be permitted to be reduced if the combustible material is protected as described in Table 13.6.2.1 and in Figure 13.6.2.1(a) through Figure 13.6.2.1(f).

13.6.2.2 Where the required clearance with no protection is 36 in. (914 mm), the clearances in Table 13.6.2.1 shall be the minimum allowable clearances. For other required clearances with no protection, minimum allowable clearance shall be calculated from maximum allowable reduction.

13.6.2.3 Unless the appliance is specifically listed for lesser clearance, the clearance after reduction shall be not less than the following:

(1) 12 in. (305 mm) to combustible walls
(2) 18 in. (457 mm) to combustible ceilings

13.6.2.4 Spacers and ties shall be of noncombustible material. No spacers or ties shall be used directly behind the appliance or the conductor.

Table 13.6.1 Standard Clearances for Solid Fuel–Burning Appliances

Type of Appliance	Above Top of Casing or Appliance; Above Top and Sides of Furnace Plenum or Bonnet		From Front		From Back[a]		From Sides[a]	
	in.	mm	in.	mm	in.	mm	in.	mm
Residential Appliances	6	152	48	1219	6[b]	152[b]	6[b]	152[b]
Steam boilers — 15 psi (103 kPa)								
Water boilers — 250°F (121°C) max.								
Water boilers — 200°F (93°C) max.								
All water walled or jacketed appliances								
Furnaces								
Gravity and forced air[c]	18	457	48	1219	18	457	18	457
Room Heaters, Fireplace Stoves,	36	914	36	914	36	914	36	914
Room Heater/Fireplace Stove Combinations,								
Ranges					**Firing Side**		**Opposite Side**	
Lined fire chamber	30[d]	762[d]	36	914	24	610	18	457
Unlined fire chamber	30[d]	762[d]	36	914	36	914	18	457

[a]Provisions for fuel storage must be located at least 36 in. (914 mm) from any side of the appliance.
[b]Adequate clearance for cleaning and maintenance must be provided.
[c]For clearances from air ducts, see NFPA 90B.
[d]Clearance to combustible material or metal cabinets. If the underside of such combustible material or metal cabinet is protected with sheet metal of not less than 24 gauge [0.024 in. (0.61 mm)], spaced out 1 in. (25 mm), the distance is permitted to be reduced to not less than 24 in. (610 mm).

13.6.2.5 With all clearance reduction systems using a ventilated air space, adequate air circulation shall be provided as described in 13.6.2.15. There shall be at least 1 in. (25 mm) between the clearance reduction system and combustible walls and ceilings for clearance reduction systems using a ventilated air space.

13.6.2.6 Mineral wool batts (blanket or board) shall have a minimum density of 8 lb/ft^3 (128.7 kg/m^3) and have a minimum melting point of 1500°F (816°C).

13.6.2.7 Insulation material used as part of a clearance reduction system shall have a thermal conductivity of 1.0 Btu-in./hr-ft^2-°F (0.14 W/m-K) or less. Insulation board shall be formed of noncombustible material.

13.6.2.8 If a single-wall connector passes through a masonry wall used as a wall shield, there shall be at least ½ in. (13 mm) of open, ventilated air space between the connector and the masonry.

13.6.2.9 There shall be at least 1 in. (25 mm) between the appliance and the protector. In no case shall the clearance between the appliance and the wall surface be reduced below that allowed in Table 13.6.2.1.

13.6.2.10 Clearances in front of the loading door, ash removal door, or both of the appliance shall not be reduced from those in Section 13.5.

13.6.2.11 Clearances from solid fuel–burning appliances to combustible material shall be permitted to be reduced, provided the combustible material is protected by an engineered protection system acceptable to the AHJ.

13.6.2.12 Engineered systems installed for the protection of combustible material shall reduce the temperature of such materials to 90°F (50°C) rise above ambient.

13.6.2.13 System design shall be based on applicable heat transfer principles, taking into account the following:

(1) The geometry of the system
(2) The heat loss characteristics of the structure behind the combustible material
(3) The possible abnormal operating conditions of the heat-producing sources

13.6.2.14 The following shall apply to clearances from solid fuel–burning appliances to combustible material:

(1) They shall be permitted to be reduced by the use of materials or products listed for protection purposes.
(2) Materials and products listed for the purpose of reducing clearance to combustibles shall be installed in accordance with the conditions of the listing and the manufacturer's instructions.

13.6.2.15 For clearance reduction systems using an air space between the combustible wall and the wall protector, adequate

Table 13.6.2.1 Reduction of Appliance Clearance with Specified Forms of Protection

Clearance Reduction Applied to and Covering All Combustible Surfaces Within the Distance Specified as Required Clearance with No Protection*	Maximum Allowable Reduction in Clearance (%)		Minimum Clearance			
			As Wall Protector		As Ceiling Protector	
	As Wall Protector	As Ceiling Protector	in.	mm	in.	mm
(a) 3½ in. (90 mm) thick masonry wall without ventilated air space	33	—	24	610	—	—
(b) ½ in. (13 mm) thick noncombustible insulation board over 1 in. (25 mm) glass fiber or mineral wool batts without ventilated air space	50	33	18	457	24	610
(c) 0.024 in. (0.61 mm), 24 gauge sheet metal over 1 in. (25 mm) glass fiber or mineral wool batts reinforced with wire or equivalent on rear face with ventilated air space	66	50	12	305	18	457
(d) 3½ in. (90 mm) thick masonry wall with ventilated air space	66	—	12	305	—	—
(e) 0.024 in. (0.61 mm), 24 gauge sheet metal with ventilated air space	66	50	12	305	18	457
(f) ½ in. (13 mm) thick noncombustible insulation board with ventilated air space	66	50	12	305	18	457
(g) 0.024 in. (0.61 mm), 24 gauge sheet metal with ventilated air space over 0.024 in. (0.61 mm), 24 gauge sheet metal with ventilated air space	66	50	12	305	18	457
(h) 1 in. (25 mm) glass fiber or mineral wool batts sandwiched between two sheets 0.024 in. (0.61 mm), 24 gauge sheet metal with ventilated air space	66	50	12	305	18	457

Notes:

(1) All clearances and thicknesses are minimums; larger clearances and thicknesses are permitted.

(2) To calculate the minimum allowable clearance, the following formula can be used: $C_{pr} = C_{un} \times [1 - (R/100)]$, where C_{pr} is the minimum allowable clearance, C_{un} is the required clearance with no protection, and R is the maximum allowable reduction in clearance.

(3) Refer to Figure 13.6.2.1(e) and Figure 13.6.2.1(f) for other reduced clearances using materials found in this table.

*See 13.6.1 through 13.6.1.3.

air circulation shall be provided by one of the methods following and illustrated in Figure 13.6.2.15.

(1) Air circulation shall be permitted to be provided by leaving all edges of the wall protector open with at least a 1 in. (25 mm) air gap.
(2) If the wall protector is installed on a single flat wall away from corners, air circulation shall be permitted to be provided by leaving only the bottom and top edges or only the side and top edges open with at least a 1 in. (25 mm) air gap.
(3) Wall protectors that cover two walls in a corner shall be open at the bottom and top edges with at least a 1 in. (25 mm) air gap.

13.6.2.16 All clearances shall be measured from the outer surface of the combustible material to the nearest point on the surface of the solid fuel–burning appliance, disregarding any intervening protection applied to the combustible material.

13.6.2.17 All clearances provided between solid fuel–burning appliances and combustible materials shall be large enough to maintain sufficient clearances between chimney connectors and combustible material as required in Section 9.5.

13.7 Accessories.

13.7.1 Factory-built accessories for solid fuel–burning appliances such as heat exchangers, stove mats, floor pads, and protection shields shall be listed and shall be installed in accordance with the terms of their listing.

13.7.2 Unlisted accessories that are acceptable to the AHJ shall be permitted to be installed in accordance with the approval of the AHJ and the appliance and accessory manufacturers' installation instructions.

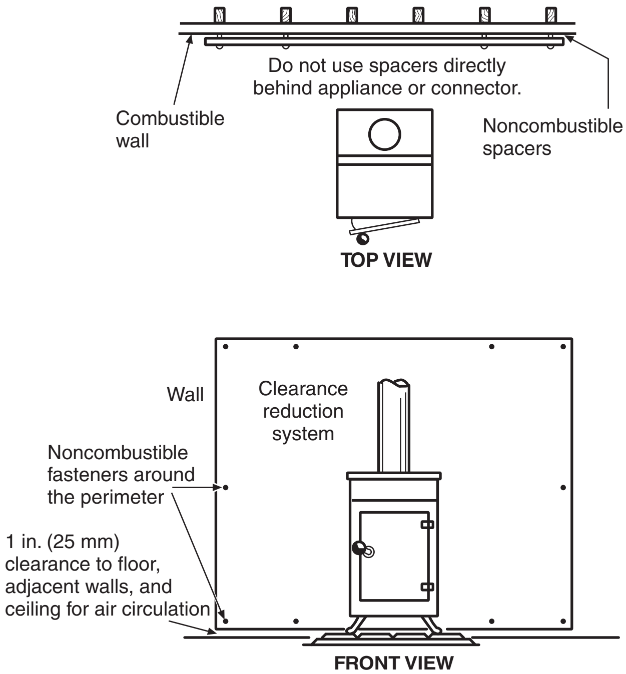

FIGURE 13.6.2.1(a) Clearance Reduction System — Fastener Location.

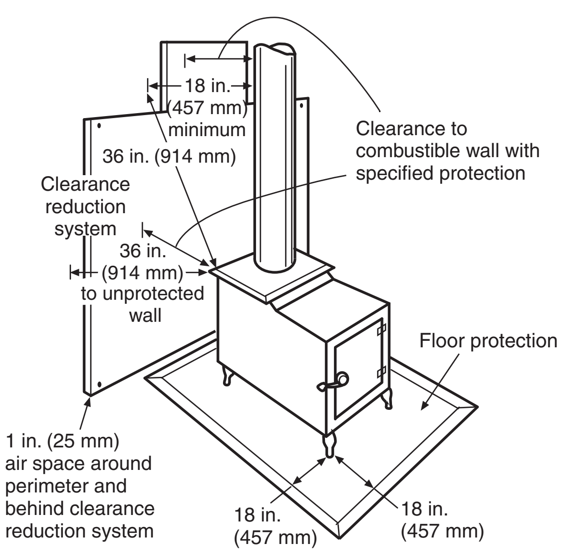

FIGURE 13.6.2.1(b) Distance to Combustible Wall/Floor.

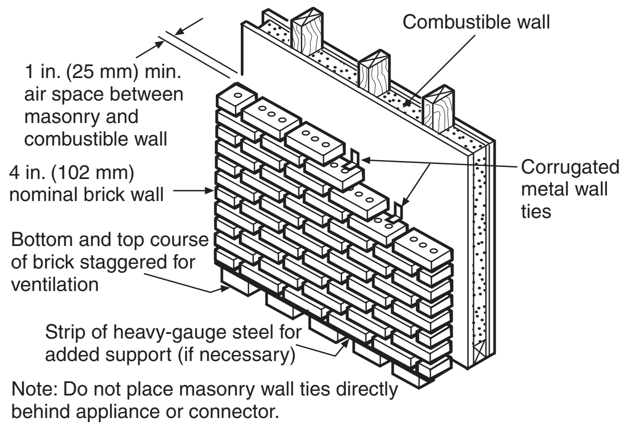

FIGURE 13.6.2.1(c) Masonry Clearance Reduction System.

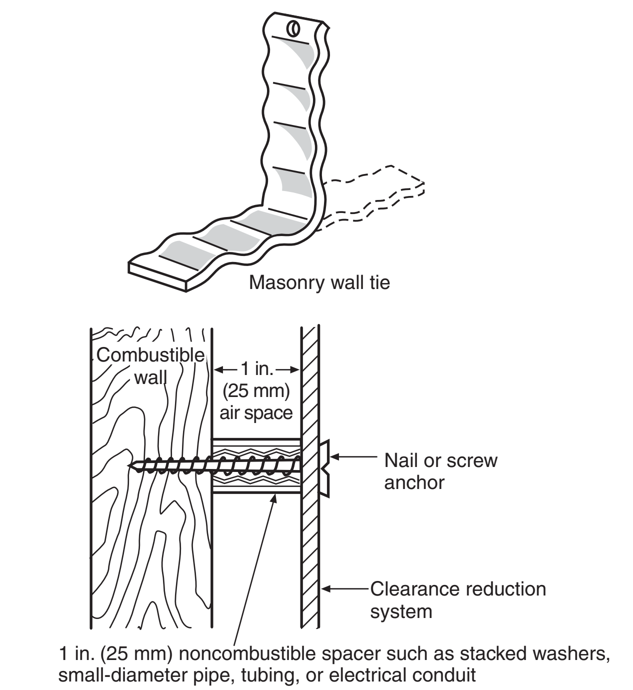
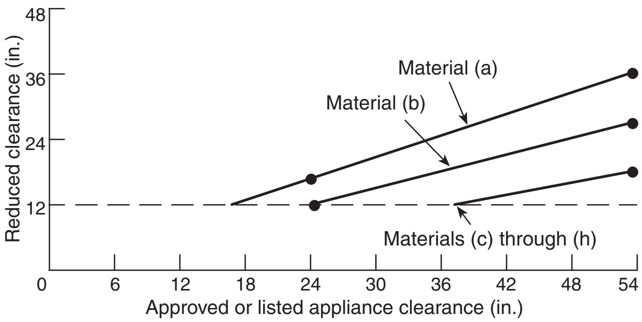


Notes:

(1) Masonry walls can be attached to combustible walls using wall ties.

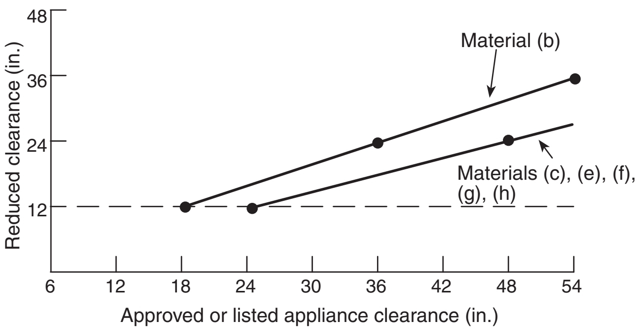
(2) Do not use spacers directly behind appliance or connector.

FIGURE 13.6.2.1(d) Fastener Detail.



For SI units: 1 in. = 25.4 mm.

FIGURE 13.6.2.1(e) Wall Protection Using Materials in Table 13.6.2.1.



Notes:

(1) Materials (a) and (d) are not expected to be used as ceiling protection.

(2) For SI units: 1 in. = 25.4 mm.

FIGURE 13.6.2.1(f) Ceiling Protection Using Materials in Table 13.6.2.1.

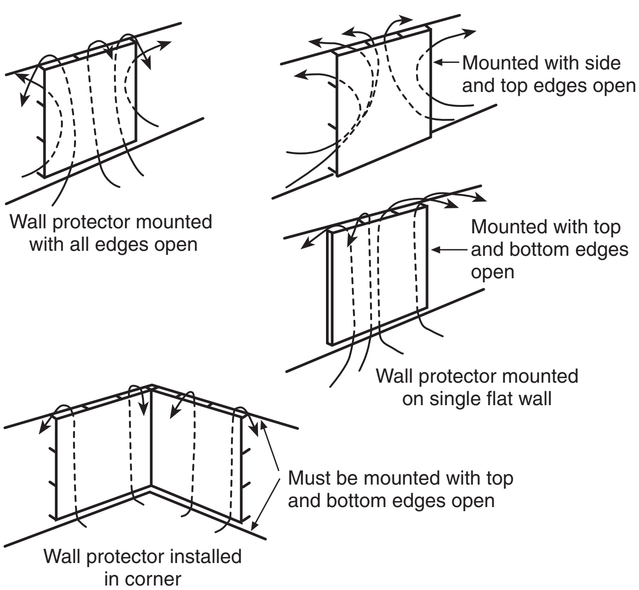


FIGURE 13.6.2.15 Air Circulation Methods.

Chapter 14 Maintenance

14.1 Initial Installation. Initial installation of chimneys, fireplaces, and vents shall allow inspection of the surroundings to determine that the required clearances have been maintained and that correct provisions for support, stabilization, future inspection, and maintenance are in place.

14.2 Annual Inspection. Chimneys, fireplaces, and vents shall be inspected at least once a year in accordance with the requirements of Section 15.2.

Exception: Type B and Type BW gas venting systems.

14.2.1 Cleaning, maintenance, and repairs shall be done if necessary.

14.3 Inspection — Connections. Connectors, spark arresters, cleanouts, and tee fittings for chimneys and for oil and pellet venting systems shall be inspected at least once a year for soundness and deposits.

Exception: Connectors for Type B gas venting systems.

14.4 Appliance or Connector Replacement.

14.4.1 When an existing appliance or connector is replaced or a new appliance is connected to a chimney, the chimney flue shall be inspected in accordance with Chapter 15.

14.4.2 The chimney shall be cleaned, lined or relined, or repaired as necessary.

14.5 Cleanout Doors. After any inspection or maintenance operation, cleanout doors and caps or plugs for cleanout tee fittings shall be closed tightly or secured in place.

14.6 Cleaning Methods. Cleaning of chimneys, if necessary, shall be done by methods that do not impair structural or thermal performance.

14.7 Evidence of Damage.

14.7.1 Chimneys, vents, and fireplaces shall be inspected, cleaned, and repaired if there is any evidence of damage to the chimney, fireplace, or vent or to the surroundings.

14.7.1.1 Factory-built chimney components or accessories shall be listed or approved for use with the specific model of factory-built chimney system if the components or accessories are available.

14.7.1.1.1 If original manufacturer's listed components or accessories are unavailable, components or accessories acceptable to and installed by a qualified agency shall be installed in accordance with the component or accessory manufacturer's installation instructions.

14.7.1.2 Factory-built fireplace components or accessories shall be listed or approved for use with the specific model of factory-built fireplace system if the components or accessories are available.

14.7.1.2.1 If original manufacturer's listed components or accessories are unavailable, components or accessories acceptable to and installed by a qualified agency shall be installed in accordance with the component or accessory manufacturer's installation instructions.

14.7.2 Inspections required by 14.7.1 shall comply with the requirements for a Level II inspection in accordance with Section 15.4.

14.8 Operating Malfunction. When inspection or an operating malfunction shows that an existing chimney, fireplace, or vent is damaged, unsuitable, or improperly sized, it shall be repaired, rebuilt, or resized to the construction and functional requirements of this standard.

14.9* Damaged or Deteriorated Liners. If the flue liner in a chimney has softened, cracked, or otherwise deteriorated so that it no longer has the continued ability to contain the products of combustion (i.e., heat, moisture, creosote, and flue gases), the liner shall be either removed and replaced, repaired, or relined with a listed liner system or other approved material that will resist corrosion, softening, or cracking from flue gases at temperatures appropriate to the class of chimney service. *(See Table 5.2.2.1.)*

14.10 Unused Openings. Unused openings in chimney flues and chimney walls shall be sealed by solid masonry with a minimum thickness equal to that of the chimney flue and wall thickness or with a listed sealing device.

Chapter 15 Inspection of Existing Chimneys

15.1* General. Inspections shall be conducted by a qualified agency.

15.1.1* Observations that are incidental to a chimney maintenance or repair task not shown in Table 15.2.1 shall not be required to comply with the minimum levels of inspection set forth in this chapter.

15.1.2 Defects that are observed during the course of such work shall be reported to the property owner, occupant, or responsible party.

15.2 Type of Inspection. The scope of the inspection, the areas of the chimney examined, and the degree of invasiveness of the inspection shall be appropriate for the conditions giving rise to the inspection.

15.2.1 The type of inspection shall be determined in accordance with Table 15.2.1.

15.2.2 The type of inspection performed shall be based on the circumstances that give rise to the inspection.

15.2.3 For situations shown in the Circumstances row of Table 15.2.1, the minimum level of inspection shall be that indicated by the column in which the situation is found.

15.2.4 For situations not shown in the Circumstances row, the type of inspection shall be based on the descriptions in the Indications row.

15.2.5 The following shall apply to examination of the chimney at a level higher than that indicated by Table 15.2.1:

(1) Nothing shall prevent the examination of all or part of the chimney at a higher level than the minimum indicated by Table 15.2.1.
(2) Partial examination of the chimney at a higher level shall not require that the entire inspection be conducted at that higher level.

15.3* Level I Inspections. A Level I inspection shall be utilized when verification of the suitability of the chimney or flue for continued service, under the same conditions and with the same or similar appliance or appliances, is needed.

15.3.1 Circumstances. A Level I inspection shall be conducted under the following circumstances:

(1) During annual inspections in accordance with Section 14.2
(2) During routine cleaning of a flue or flues within the chimney
(3) At the time of replacement of one or more connected appliances with an equal number of appliances of similar type, input rating, and efficiency, in accordance with Section 14.4
(4) At other times as indicated in Section 15.3

15.3.2 Scope and Access. Level I inspections shall include examination of readily accessible portions of the chimney and accessible portions of the connected appliance and chimney connection.

15.3.2.1 The following shall apply to the inspection of locations with panels, doors, or coverings:

(1) The chimney exterior and surroundings shall be inspected at locations that can be accessed without removal of panels, doors, or coverings.
(2) Where panels, doors, or coverings are opened as part of the performance of another task, such as chimney cleaning, such locations shall be examined as part of a Level I inspection.

15.3.2.2 Readily accessible areas of the chimney flue that can be observed through existing openings, such as a thimble, cleanout opening, or flue termination, shall be examined for the presence of a continuous flue liner, proper installation, and no damage or deterioration.

15.3.2.3 The following shall apply to inspection of flues:

(1) Where an inspection is conducted in accordance with Section 14.2, the inspection shall include all flues within the chimney and connected appliances.
(2) An inspection conducted during cleaning or appliance replacement shall include the flue or flues being cleaned and the appliance or appliances connected to each.

15.3.2.4 The inspection shall include verification that the flue or flues being inspected are free of combustible deposits and blockage or obstruction.

15.3.2.5 The connected appliance or appliances, their chimney connectors, and surroundings shall be examined for proper clearances, protection, damage or deterioration, and observable evidence of operating malfunction.

15.3.2.6 Chimney connector inspection shall meet the following criteria:

(1) Connectors shall be examined for proper support and fastening of joints, pitch, and securement to the chimney.
(2) Connectors shall be examined for damage, deterioration, internal blockage or obstruction, and freedom from combustible deposits.

15.3.2.7 Internal surfaces of fireplaces and smoke chambers shall be examined for damage and deterioration, combustible deposits, and evidence of operating malfunction.

Table 15.2.1 Selection of Inspection Type

	Inspection Types		
Criteria	**Level I**	**Level II**	**Level III**
Scope	Readily accessible areas of chimney, structure, and flue; lack of obstruction or combustible deposits in flue; basic appliance installation and connection	All subjects of a Level I inspection; proper construction and condition of accessible portions of the chimney structure and all enclosed flues; proper clearances from combustibles in accessible locations; size and suitability of flues for connected appliances	All subjects of Level I and Level II inspections; proper construction and condition of concealed portions of chimney structure and enclosed flues; proper clearances from combustibles
Degree of access required	Readily accessible portions of chimney exterior and interior; accessible portions of appliance and chimney connection	All accessible portions of the chimney exterior and interior, including areas within accessible attics, crawl spaces, and basements, and accessible portions of the appliance and chimney connection; includes inspection by video scanning or other means	External and internal portions of chimney structure, including concealed areas of the building or chimney; includes removal of components of building or chimney where necessary, but only as necessary to gain access to areas that are the subject of the inspection
Circumstances	Annual inspection as required by Section 14.2; during routine cleaning of chimney flue; upon direct replacement of connected appliance with one of similar type, input rating, and efficiency	Upon addition or removal of one or more connected appliances or replacement of appliance with one of dissimilar type, input rating, or efficiency; prior to relining or replacement of flue lining; upon sale or transfer of the property; after operating malfunction or external event likely to have caused damage to the chimney	Where necessary for the investigation of an incident that has caused damage to the chimney or building; where a hazard detected or suspected as the result of a Level I or II inspection cannot be fully evaluated without access to concealed areas
Indications	For verification of suitability of the chimney for continued service, under the same conditions and with the same appliance or appliances	For verification of suitability of the chimney for new or changed conditions of service; Level I inspection not sufficient to determine serviceability of the chimney	When construction of all or part of chimney is deemed critical to its renewed or continued use; required only for those areas that cannot be properly evaluated by a Level I or Level II inspection

Note: The inspection is not required when the last connected appliance is removed and chimney use is discontinued.

15.3.2.7.1 Fireplace inserts, stoves, or accessories shall be removed from the fireplace as necessary to permit such examination.

15.3.2.7.2 The means of connecting a fireplace insert or stove to the chimney flue shall be examined for compliance with 13.4.5.

15.3.2.7.3* Fireplace inserts, stoves, or accessories shall not be required to be removed when the venting system can be thoroughly cleaned without such removal.

15.4* Level II Inspections. A Level II inspection is indicated when verification of the suitability of the chimney for new or changed conditions of service is needed or when a Level I inspection is not sufficient to determine the serviceability of the chimney.

15.4.1 Circumstances. A Level II inspection shall be conducted under the following circumstances:

(1)* Upon addition or removal of one or more connected appliances or upon replacement of an appliance with one or more of dissimilar type, input rating, or efficiency, unless the last connected appliance is removed and chimney use will be discontinued
(2) Prior to relining of a flue or replacement of flue lining, in accordance with 7.1.10
(3) Upon sale or transfer of the property

(4) After a building or chimney fire, weather or seismic event, or other incident likely to have caused damage to the chimney
(5) At other times as indicated in Section 15.3

15.4.2 Scope and Access. Level II inspections shall include all accessible portions of the chimney exterior and interior, including the following:

(1) Areas within accessible attics, crawl spaces, and basements
(2) Accessible portions of the appliance and chimney connection

15.4.2.1 The inspection shall include examination of all areas covered in 15.3.2 for Level I inspections.

15.4.2.2 All areas of the chimney and its surroundings that can be accessed without the removal or destruction of permanently attached portions of the chimney or building structure shall be inspected, including examination of the following:

(1) Locations within attics
(2) Crawl spaces
(3) Basements that can be accessed through doors, hatches, or other openings that do not require removal of permanently attached parts of the building

15.4.2.3 The inspection shall include examination of accessible areas of all chimney flues and the internal surfaces of all flue liners incorporated within the chimney with video scanning equipment or other means used as necessary to observe those areas.

15.4.2.4 The inspection shall include verification of proper clearances from the chimney to combustibles at all locations that can be accessed as described in 15.3.2.2.

15.4.2.5 The inspection shall include evaluation of the proper type of flue lining material and flue sizing for the type and input rating of the connected appliances.

15.4.2.5.1 Sizing of flues for solid fuel–burning and pellet fuel–burning equipment shall be in accordance with this standard.

15.4.2.5.2 Sizing of flues for gas appliances shall be in accordance with NFPA 54.

15.4.2.5.3 Sizing of flues for liquid fuel appliances shall be in accordance with NFPA 31.

15.5* Level III Inspections. A Level III inspection shall be utilized for concealed areas.

15.5.1 Areas Required. A Level III inspection shall be required only for those areas suspected of malfunction or damage that cannot be properly evaluated by a Level I or Level II inspection.

15.5.2 Circumstances. A Level III inspection shall be conducted under the following circumstances:

(1) Where necessary for the investigation of a building or chimney fire, weather or seismic event, or other incident known to have caused damage to the chimney or building
(2) Where a hazard detected or suspected as the result of Level I or II inspection cannot be fully evaluated without access to concealed areas
(3) At other times as indicated in Section 15.5

15.5.3 Scope and Access. A Level III inspection shall include examination of concealed areas of the chimney suspected of damage or malfunction.

15.5.3.1 The inspection shall include examination of all areas covered in 15.3.2 for Level I inspections and in 15.4.2 for Level II inspections.

15.5.3.2 Examination of the chimney shall include concealed areas that can be accessed only by removal or destruction of permanently attached portions of the chimney or building structure, as necessary to determine compliance with this standard.

Annex A Explanatory Material

Annex A is not a part of the requirements of this NFPA document but is included for informational purposes only. This annex contains explanatory material, numbered to correspond with the applicable text paragraphs.

A.3.2.1 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

A.3.2.2 Authority Having Jurisdiction (AHJ). The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A.3.2.4 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A.3.3.1 Accessible (for Inspections). Access can be described as the capability of being reached for the purpose of inspection, maintenance, or repair. Access could first require the movement or removal of a panel, door, or other covering, the use of ladders, or the use of a common tool, such as a screwdriver or wrench. Access does not require any destructive actions to the building or property.

A.3.3.1.1 Readily Accessible (for Inspections). Readily accessible can be described as being quickly or easily reached for inspection, maintenance, or repair. Readily accessible would not require the use of tools for opening or removal of any panel, door, or other covering, nor would it require the use of ladders.

A.3.3.2.1 Factory-Built Fireplace Accessories. These accessories include, but are not limited to, such items as decorative shrouds, glass or screen door assemblies, grates, blowers, log lighters intended for the ignition of solid fuel, gas log decorative appliances, spark arrestors, and chimney caps.

A.3.3.2.2 Masonry Fireplace Accessories. These accessories include, but are not limited to, such items as heat exchangers, glass or screen door assemblies, grates, andirons, blowers, log lighters intended for the ignition of solid fuel, fire backs intended to reflect heat or reduce heat exposure, dampers, gas log decorative appliances, spark arrestors, chimney caps, and ash receptacle doors.

A.3.3.4.2 Direct Vent Appliance. Direct vent appliances are sometimes called sealed combustion system applicances.

A.3.3.29.1.3 Type HT Factory-Built, Residential-Type and/or Building Heating Appliance–Type Chimney. Chimneys designated as Type HT are listed for venting flue products not exceeding 1000°F (538°C) continuous. In addition, they comply with the 10-minute 2100°F (1149°C) temperature test requirements of ANSI/UL 103, *Standard for Factory-Built Chimneys for Residential Type and Building Heating Appliances*. Such test requirements were developed to simulate the effects of a chimney fire. Type HT chimneys are required on certain controlled-combustion solid fuel–burning appliances because such appliances are often associated with a higher likelihood of creosote buildup and associated occurrence of chimney fires.

A.3.3.51 Crown. Masonry chimney termination includes considerations of weather protection for the chimney and thermal expansion of the flue liner.

A chimney crown offers the advantages of extension beyond the sides of the chimney to direct water away from both the flue and the chimney. A properly sealed space between the liner and the crown to allow vertical movement of the flue should be a design feature of prefabricated or site-constructed masonry or metal crowns.

A site-applied wash or splay may require frequent maintenance to ensure that it remains impervious to water penetration. Because a splay or a wash does not extend out past the chimney, it allows water to run down the sides of a chimney, which can result in chimney deterioration. Care must be taken to provide for vertical movement of the flue liner as required in 7.2.13.4.

See Figure A.3.3.51.

A.3.3.56.1 Mechanical Draft. When a fan is located so as to push the flue gases through the chimney or vent, a forced mechanical draft is created. When a fan is located so as to pull the flue gases through the chimney or vent, an induced mechanical draft is created.

A.3.3.80 Gas Appliance Categories. For additional information on appliance categorization, see the appropriate Z21 and Z83 American National Standards.

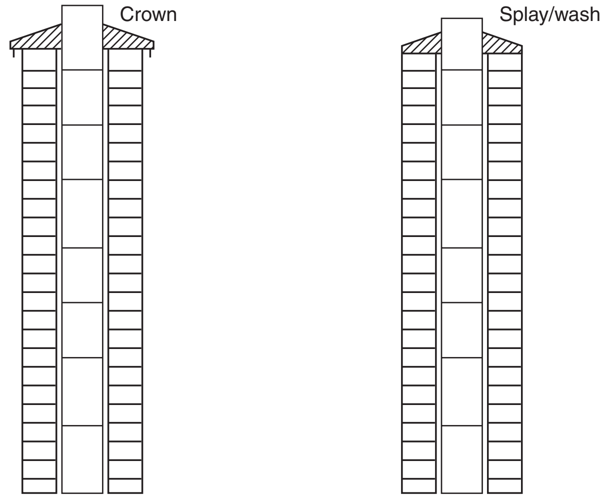

FIGURE A.3.3.51 Chimney Crown and Splay/Wash.

A.3.3.131.1 Engineered Venting or Chimney System. Approved engineering methods can include the following:

(1) The vent capacity tables in NFPA 54
(2) The fuel-burning equipment manufacturers' venting instructions
(3) Drawings, calculations, and specifications provided by the venting equipment manufacturer or a professional engineer
(4) Use of calculations from *ASHRAE Handbook: HVAC Systems and Equipment*, Chapter 31
(5) Application of the VENTII (version 4.1 or more current) computer program, developed under Gas Research Institute sponsorship for vent design and analysis
(6) The listed metal liner sizing and listed cast-in-place liner sizing tables in NFPA 31

A.3.3.142 Vent. Type B gas vents are tested with flue gases at 400°F (204°C) above ambient. Type BW gas vents are tested with flue gases at 480°F (249°C) above ambient and are limited to use only with certain gas-fired wall furnaces. Special Gas Vents may be certified at a variety of flue gas temperature rises up to 480°F (249°C) above ambient. Pellet vents are tested with flue gases at 500°F (260°C) above ambient. Type L vents are tested with flue gases at 500°F (260°C) above ambient.

A.4.1 See 3.3.131.1.

A.4.1.2.5(3) Documents that provide listing requirements include ANSI/UL 2034, *Standard for Single and Multiple Station Carbon Monoxide Alarms*, and IAS 6-96, *IAS-US Requirements for Carbon Monoxide Alarms for Residential Use*. Additionally, NFPA 720 provides guidance for the installation of carbon monoxide warning equipment.

A.6.1.3.2 See 3.3.131.1.

A.6.1.4.1 Duct wrap systems, such as those listed to ASTM E2336, *Standard Test Methods for Fire Resistive Grease Duct Enclosure Systems*, are generally used with commercial kitchen vent systems and are not appropriate for preventing heat transfer from the chimney to nearby combustibles. In addition, factory-built chimneys are listed products that have not been tested in conjunction with duct wrap. Therefore, there is no way of determining if the duct wrap/chimney combination will provide the necessary fire resistance. If duct wrap is used within a rated enclosure, it should be properly secured and should not violate the chimney air space requirements.

A.6.3 See 3.3.131.1.

A.7.1.11 See 3.3.131.1.

A.7.1.12 Many residential appliances, including pellet stoves, Category I gas appliances, and most residential oil-fired appliances, do not create sustained positive pressure inside masonry chimneys even though they are equipped with combustion blowers.

A.7.3.1.3 However, this does not eliminate the firestopping requirements in 7.1.6.

A.8.1.8 See 3.3.131.1.

A.9.3.1(3) See 3.3.131.1.

A.9.5.2 The system design should be based on applicable heat transfer principles, taking into account the geometry of the system, the heat loss characteristics of the structure behind the combustible material, and the possible abnormal operating conditions of heat-producing sources.

A.9.7.8 Listed equipment includes components such as heat reclaimers, draft regulators, and safety controls.

A.9.11 For information concerning the use and installation of draft regulators with oil-burning appliances, see NFPA 31.

A.10.1.4 ANSI/UL 1738, *Standard for Venting Systems for Gas-Burning Appliances, Categories II, III, IV*, covers the construction of special gas vents.

A.10.6 Additional requirements for the installation of venting systems serving gas appliances appear in NFPA 54.

A.10.7.2.1 For information on ventilation of restaurant cooking equipment, see NFPA 96.

A.11.2 See Figure A.11.2(a) and Figure A.11.2(b).

A.11.2.10 Factory-built accessories for fireplaces include devices that could alter the combustion or heating characteristics of the fireplace. These products should meet the requirements of ANSI/UL 907, *Fireplace Accessories*; ANSI Z21.11.2, *Gas-Fired Room Heaters — Volume II, Unvented Room Heaters*; Z21.60/CSA 2.26, *Decorative Gas Appliances for Installation in Solid-Fuel Burning Fireplaces*; or ANSI Z21.84, *Manually Lighted, Natural Gas, Decorative Gas Appliances for Installation in Solid-Fuel Burning Appliances*.

In developing the 2013 edition, the committee received reports that some building and energy codes indicate that gasketed or tight-fitting doors should be used on masonry fireplaces to minimize heat loss through the fireplace opening when not in operation. Many existing masonry fireplaces were not designed to be operated with such doors in the closed position. Operation with closed gasketed or tight-fitting doors has the risk of causing an increase in temperature of the masonry material. If operation continues for an extended period, the masonry material could be capable of transferring enough heat to ignite nearby combustibles, even if the minimum separation distance specified in 11.2.5 is provided. In addition, operation of a masonry fireplace with gasketed or tight-fitting doors in the closed position can result in incomplete combustion.

A.13.2.1 Sufficient clearance should be maintained to allow cleaning of surfaces; the replacement of air filters, blowers, motors, controls, and chimney connectors; the lubrication and servicing of moving parts; and the adjustment and servicing of stokers, if provided.

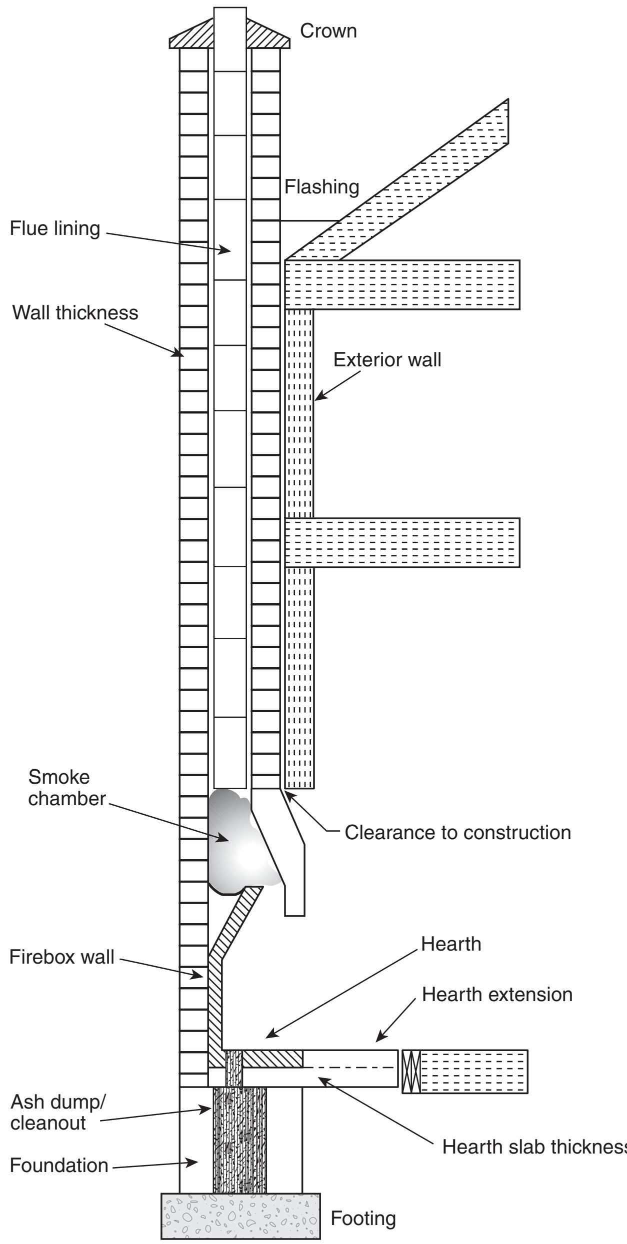

FIGURE A.11.2(a) Fireplace and Chimney Details.

A.13.4.4 Some appliances could perform incorrectly with the "three times" rule. In some cases, smaller cross-sectional areas could be needed to ensure proper performance. The appliance manufacturer's instructions should be consulted for each installation. Natural draft residential-type appliances are designed with a combustion system that relies on natural draft created within the appliance or by the venting system to maintain the combustion process.

A.13.4.5.1(4) Some appliances could perform incorrectly with the "three times" rule. In some cases, smaller cross-sectional areas could be needed to ensure proper performance. The

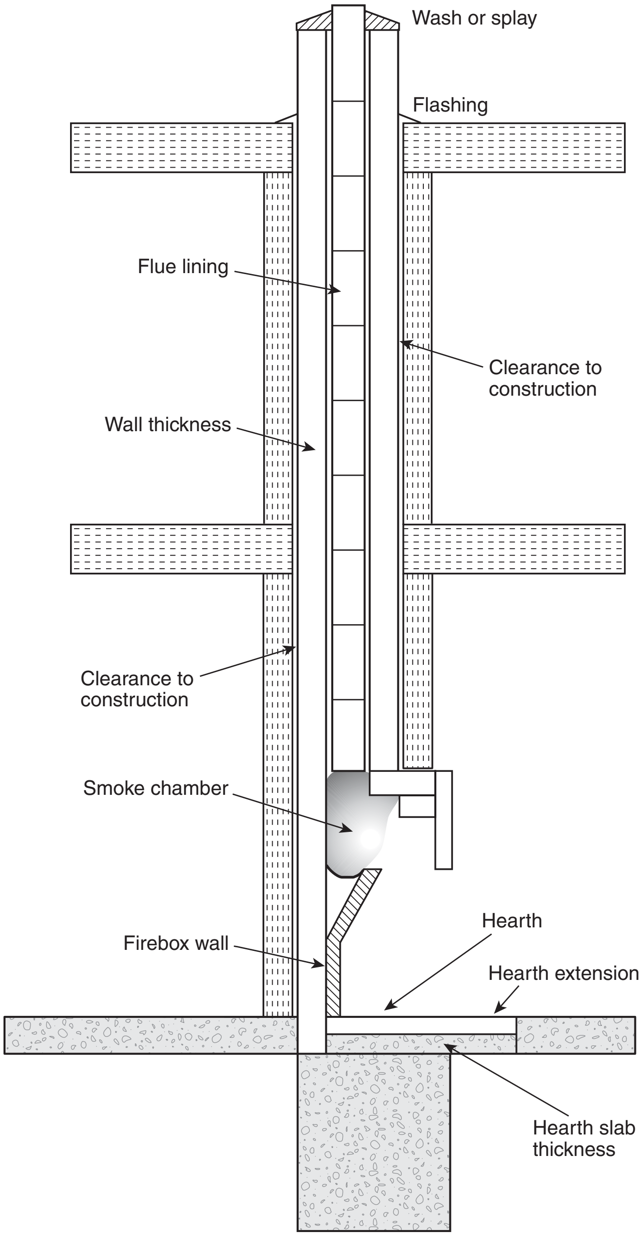

FIGURE A.11.2(b) Interior Block Chimney.

appliance manufacturer's instructions should be consulted for each installation.

A.14.9 Deterioration of the interior surface of a liner that results in softening or corrosion of liner materials (e.g., powdering or crumbling of liner materials or attack on metal surfaces resulting in perforation) indicates an inability of the liner to continue to perform its intended function.

Damage to liners that is from either structural or thermal causes and results in cracks that would allow moisture to penetrate the liner or would preclude the liner from containing flames or the products of combustion, or both, indicates an inability of the liner to continue to perform its intended function.

A.15.1 This chapter covers the inspection of chimneys and is intended primarily for the inspection of residential chimneys, but at the discretion of the inspector, it could apply to industrial or commercial chimneys serving certain appliances.

There are different types of inspections, ranging from superficial observation to an in-depth inspection in which portions of the chimney or building structure are removed, or other destructive methods are used to check hidden portions of a system. Inspections can be triggered by many circumstances, ranging from routine maintenance activities to a complete re-evaluation following a destructive event such as an earthquake. This chapter is intended to delineate, as precisely as possible, the inspection activities appropriate for different circumstances. The application of these requirements to specific situations requires judgment on the part of the inspector and should be in accordance with the Indications row of Table 15.2.1.

Although this chapter is concerned with the inspection of chimneys, the chimney cannot be considered apart from the appliance connected to it. Any defects or potential hazards encountered during such work should not be ignored and should be brought to the attention of the owner, occupant, or responsible party.

A.15.1.1 Certain minor tasks, such as installation of a chimney cap or flashing repair, are so limited in scope that they do not trigger a full inspection of the chimney. However, any defects or potential hazards encountered during such work should not be ignored and should be brought to the attention of the responsible party.

A.15.3 A Level I inspection is required to ensure the minimum acceptable levels of safety for a chimney. Unless otherwise stated, a Level I inspection is limited to readily accessible areas. The following list indicates some of the items to be included in a Level I inspection, to the extent that they are readily accessible and included in the installation being inspected. The following list should not be considered all-inclusive:

(1) Level of cleanliness of venting system
(2) Verification that the flue is not blocked or significantly restricted or obstructed
(3) Appliance clearance
(4) General condition of appliance
(5) Chimney or vent and its connector for general suitability for appliance
(6) Chimney or vent and its connector for type, material, and condition
(7) Chimney or vent and its connector clearance
(8) Chimney or vent and its connector joint security
(9) Chimney or vent and its connector for support and stability
(10) Chimney or vent and its connector for offset, rise, or slope
(11) Chimney connector or vent connector accessories (barometric damper, damper, draft hood, heat reclaimer)
(12) Chimney liner for proper support
(13) Appropriateness of the chimney liner type for appliance
(14) That the chimney liner is present and free of readily visible defects, distortion, and spalling
(15) That flue cleanouts are present and properly installed
(16) Condition of wash when readily accessible
(17) That the chimney cap, if present, does not contribute to flue blockage/restriction
(18) That the spark arrester, if present, is not obstructed

(19) That the top installed damper, if present, does not obstruct the flue
(20) Wall pass-through general condition
(21) That the connector is secure where it meets the wall pass-through, chimney, or vent
(22) General condition of hearth and hearth extension
(23) Hearth extension sizing
(24) General condition of the hearth extension, fireplace facing, fire chamber, and smoke chamber, with special emphasis on tight-fitting joints between assemblies
(25) Type and condition of fire chamber lining
(26) Clearance to combustible trim and mantels around fireplace opening
(27) Operation and closure of damper assembly
(28) Smoke chamber general condition
(29) Smoke chamber accessibility
(30) Smoke chamber transition to flue
(31) That air circulation grilles (openings) around factory-built fireplace are not blocked or restricted
(32) Freedom from rust or corrosion of readily accessible metal parts in factory-built fireplaces and chimneys
(33) That mechanical draft systems are operable and free from rust and corrosion

A.15.3.2.7.3 This paragraph is provided for cases where removing the device is not necessary to gain access to flue passageways needing inspection. It covers devices such as grates or heat exchangers that do not fill or block the fireplace opening. It also covers fireplace inserts or stoves that are directly connected to the chimney flue, where combustion products are contained in the connection and do not contact the fireplace surfaces.

A.15.4 A Level II inspection is limited to accessible parts of the chimney to include attic, basement, and crawl spaces. The following list (which is in addition to the list in A.15.3 for Level I inspection and which should not be considered all-inclusive) indicates some of the items to be included in a Level II inspection, to the extent that they are readily accessible and included in the installation being inspected:

(1) Chimney wall material
(2) Condition of chimney walls
(3) Attic insulation shield for factory-built chimneys and factory-built fireplace chimneys
(4) Housing and shrouds for factory-built chimneys and factory-built fireplace chimneys
(5) Factory-built chimney support type
(6) Factory-built chimney and factory-built fireplace chimney assembled with appropriate parts
(7) Factory-built chimney and factory-built fireplace chimney clearances
(8) Factory-built chimney and factory-built fireplace chimney attachment to appliance
(9) That the venting system is properly sized for the appliance
(10) Height and dimensions of liner
(11) Installation and condition of offsets in flue
(12) That unused openings (into flue) are properly sealed
(13) Construction of wash
(14) Expansion joint between flue and wash
(15) Condition of flashing
(16) Condition of crickets, when present
(17) Chimney connector or vent connector gauge (material thickness)
(18) That the chimney and vent connector diameter is proper for appliance(s) connected
(19) That the wall pass-through is properly installed with adequate clearance and installation details
(20) Chimney or vent connector configuration (appropriate dimensions for sizing and compared with vent or chimney)
(21) Manifold sizing
(22) Combustion air supplied for fireplaces in accordance with Section 11.4
(23) Condition of outside air inlets, outlets, and ducting in accordance with Section 11.4
(24) Ash dump
(25) Combustible framing/forms under hearth or hearth extension of masonry fireplaces
(26) Fireplace opening size (ratio with flue) of masonry fireplaces
(27) Size of throat of masonry fireplaces
(28) Smoke chamber dimensions (angle/height) of masonry fireplaces
(29) Smoke chamber lining (parged, firebrick, etc.) of masonry fireplaces
(30) Smoke shelf area of masonry fireplaces
(31) Factory-built fireplace brand, model, and listing
(32) That factory-built fireplace glass doors and accessories (inserted items) are approved
(33) Factory-built fireplace hearth platform and covering

When conducting a Level II inspection on any type of factory-built chimney or appliance, the inspector should request the product installation instructions from the building owner or occupant for review prior to completing the inspection.

A.15.4.1(1) This item should not be interpreted to include the removal or disconnection of an appliance and subsequent replacement or reconnection that occurs during the course of routine cleaning and maintenance activities.

A.15.5 A Level III inspection encompasses a complete evaluation of the chimney, including verification of proper materials and clearances to combustibles.

The following list (which is in addition to the lists in A.15.3 and A.15.4 for Level I and Level II inspections and which should not be considered all-inclusive) indicates some of the items to be included in a Level III inspection, to the extent that they are readily accessible and included in the installation being inspected:

(1) Firestopping
(2) Debris in annular space of factory-built chimney and factory-built fireplace chimney
(3) Clearances inside the chase housing of factory-built chimneys and factory-built fireplace chimneys
(4) Masonry foundation
(5) Masonry foundation depth and dimension
(6) Masonry foundation soil conditions
(7) That the space around the chimney liner is adequate
(8) That seismic requirements, where required, have been met
(9) Thickness of fireplace walls
(10) Clearance around fireplace walls
(11) Smoke chamber wall thickness
(12) Smoke chamber clearance
(13) Factory-built fireplace clearance

(14) That the factory-built fireplace hearth strip is properly installed
(15) That the factory-built fireplace installation is stable
(16) Connection between factory-built fireplace and its chimney
(17) Factory-built fireplace hearth extensions per manufacturer's instructions, including U values

NFPA®214

Standard on

Water-Cooling Towers

2016 Edition

This edition of NFPA 214, *Standard on Water-Cooling Towers*, was prepared by the Committee on Water-Cooling Towers. It was issued by the Standards Council on November 14, 2015, with an effective date of December 4, 2015, and supersedes all previous editions.

This edition of NFPA 214 was approved as an American National Standard on December 4, 2015.

Origin and Development of NFPA 214

The subject of the protection of water-cooling towers was first considered by the NFPA Committee on Building Construction in 1957, and a progress report on the subject was published in the Advance Reports of that year. In 1958, a new Committee on Water-Cooling Towers was appointed, and a Tentative Standard on Fire Protection of Water-Cooling Towers proposed by the Committee was adopted by the Association. Final adoption of NFPA 214, *Standard on Water-Cooling Towers*, was secured in 1959. Revised editions were published in 1961, 1966, 1968, 1971, 1976, 1977, 1983, 1988, and 1992. The 1996 edition of the standard reinforced a performance-based approach to fire protection for water-cooling towers. The scope was also changed to include protection of field-erected water-cooling towers.

The changes in the 2000 edition reflected the new *Manual of Style for NFPA Technical Committee Documents*. The 2005 edition added requirements for pilot line detectors.

The 2011 edition made several clarifications to improve NFPA 214's functionality for the user and to coordinate with other documents.

The 2016 edition has better aligned the sprinkler requirements within the Standard with the types of systems defined in NFPA 13, *Standard for the Installation of Sprinkler Systems*.

2016 Edition

IMPORTANT NOTE: This NFPA document is made available for use subject to important notices and legal disclaimers. These notices and disclaimers appear in all publications containing this document and may be found under the heading "Important Notices and Disclaimers Concerning NFPA Documents." They can also be obtained on request from NFPA or viewed at www.nfpa.org/disclaimers.

UPDATES, ALERTS, AND FUTURE EDITIONS: New editions of NFPA codes, standards, recommended practices, and guides (i.e., NFPA Standards) are released on scheduled revision cycles. This edition may be superseded by a later one, or it may be amended outside of its scheduled revision cycle through the issuance of Tentative Interim Amendments (TIAs). An official NFPA Standard at any point in time consists of the current edition of the document, together with any TIAs and Errata in effect. To verify that this document is the current edition or to determine if it has been amended by any TIAs or Errata, please consult the National Fire Codes® Subscription Service or visit the Document Information (DocInfo) pages on the NFPA website at www.nfpa.org/docinfo. In addition to TIAs and Errata, the DocInfo pages also include the option to sign up for Alerts for each document and to be involved in the development of the next edition.

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates that explanatory material on the paragraph can be found in Annex A.

A reference in brackets [ ] following a section or paragraph indicates material that has been extracted from another NFPA document. As an aid to the user, the complete title and edition of the source documents for extracts in mandatory sections of the document are given in Chapter 2 and those for extracts in informational sections are given in Annex C. Extracted text may be edited for consistency and style and may include the revision of internal paragraph references and other references as appropriate. Requests for interpretations or revisions of extracted text shall be sent to the technical committee responsible for the source document.

Information on referenced publications can be found in Chapter 2 and Annex C.

Chapter 1 Administration

1.1* Scope. This standard applies to fire protection for field-erected and factory-assembled water-cooling towers of combustible construction or those in which the fill is of combustible material.

1.2 Purpose. The purpose of this standard is to provide a reasonable degree of protection for life and property from fire where water-cooling towers are located.

Chapter 2 Referenced Publications

2.1 General. The documents or portions thereof listed in this chapter are referenced within this standard and shall be considered part of the requirements of this document.

2.2 NFPA Publications. National Fire Protection Association, 1 Batterymarch Park, Quincy, MA 02169-7471.

Chapter 3 Definitions

3.1 General. The definitions contained in this chapter shall apply to the terms used in this standard. Where terms are not defined in this chapter or within another chapter, they shall be defined using their ordinarily accepted meanings within the context in which they are used. *Merriam-Webster's Collegiate Dictionary*, 11th edition, shall be the source for the ordinarily accepted meaning.

3.2 NFPA Official Definitions.

3.2.1* Approved. Acceptable to the authority having jurisdiction.

3.2.2* Authority Having Jurisdiction (AHJ). An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

3.2.3 Labeled. Equipment or materials to which has been attached a label, symbol, or other identifying mark of an organization that is acceptable to the authority having jurisdiction and concerned with product evaluation, that maintains periodic inspection of production of labeled equipment or materials, and by whose labeling the manufacturer indicates compliance with appropriate standards or performance in a specified manner.

3.2.4* Listed. Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

3.2.5 Shall. Indicates a mandatory requirement.

3.2.6 Should. Indicates a recommendation or that which is advised but not required.

3.3 General Definitions.

3.3.1 Air Travel. The distance that air travels through the cooling tower fill by tower type, measured horizontally in crossflow towers (as the fill packing width), or vertically in counterflow towers (as the fill packing depth).

3.3.2* Cell. The smallest tower subdivision that can function as an independent unit with regard to air and water flow.

3.3.3 Combustible Material. A material that, in the form in which it is used and under the conditions anticipated, will ignite and burn; a material that does not meet the definition of noncombustible.

3.3.4* Cooling Tower.

3.3.4.1* ***Counterflow.*** A cooling tower classification in which the water flows countercurrent to the airflow.

3.3.4.2* ***Crossflow.*** A cooling tower classification in which the airflow is essentially perpendicular to the flow of water.

3.3.4.3 ***Deluge Sprinkler System.*** A sprinkler system employing open sprinklers or nozzles that are attached to a piping system that is connected to a water supply through a valve that is opened by the operation of a detection system installed in the same areas as the sprinklers or the nozzles. When this valve opens, water flows into the piping system and discharges from all sprinklers or nozzles attached thereto. [**13,** 2016]

3.3.4.4 ***Dry Pipe Sprinkler System.*** A sprinkler system employing automatic sprinklers that are attached to a piping system containing air or nitrogen under pressure, the release of which (as from the opening of a sprinkler) permits the water pressure to open a valve known as a dry pipe valve, and the water then flows into the piping system and out the opened sprinklers. [**13,** 2016]

3.3.4.5* ***Mechanical-Draft.*** A cooling tower classification in which air movement depends on fans or blowers.

3.3.4.6* ***Natural-Draft.*** A cooling tower containing no fans or blowers, in which air movement depends on the difference in densities of the heated air inside the tower and the cooler air outside.

3.3.5 Film Fill. Water-cooling media made of formed plastic sheets and placed parallel to tower air travel at evenly spaced intervals.

3.3.6* Fire-Resistant Partition. A tight, continuous partition suitable for use in a cooling tower environment that has a fire resistance rating of 20 minutes or more in accordance with Section 4.9.

3.3.7 Noncombustible Material. A material that, in the form in which it is used and under the conditions anticipated, will not ignite, burn, support combustion, or release flammable vapors, when subjected to a fire or heat. Materials that are reported as passing ASTM E136, *Standard Test Method for Behavior of Materials in a Vertical Tube Furnace at 750°C,* shall be considered noncombustible materials. [**13,** 2016]

3.3.8 Pilot Line Detector. An automatic sprinkler or thermostatic fixed temperature release device used as a detector to pneumatically or hydraulically release the system actuation valve.

3.3.9 Preaction Sprinkler System. A sprinkler system employing automatic sprinklers that are attached to a piping system that contains air that might or might not be under pressure, with a supplemental detection system installed in the same areas as the sprinklers. [**13,** 2016]

3.3.10 System Actuation Valve. The main valve that controls the flow of water into the fire protection system.

3.3.11 Wet Pipe Sprinkler System. A sprinkler system employing automatic sprinklers attached to a piping system containing water and connected to a water supply so that water discharges immediately from sprinklers opened by heat from a fire. [**13,** 2016]

Chapter 4 General Requirements

4.1 Construction Materials of Water-Cooling Towers.

4.1.1 Where the cooling tower's structure, fan, distribution system, louvers, and fill and drift eliminator materials are all of noncombustible materials, a fire protection system shall not be required.

4.1.2 If any of the construction materials are combustible and the factors in Section 4.2 necessitate it, fire protection shall be provided in accordance with Chapter 5, and towers shall be located in accordance with Chapter 4.

4.2* Fire Risk Analysis. A fire risk analysis shall be conducted. The following are some of the factors that shall be considered in determining the extent and method of fire protection required for induced-draft and natural-draft water-cooling towers:

(1) Importance to continuity of operation
(2)* Size and construction of tower
(3) Type of tower
(4) Location of tower
(5) Water supply
(6) Value of tower
(7) Climate
(8)* Water delivery time
(9) Environment

(10) Rooftop towers
(11) Limited access
(12) Materials of construction *(see Section 4.1)*

4.3 Combustible Exterior Surfaces. Water-cooling towers with combustible exterior surfaces, including the deck, distribution basins, and so forth, shall be located at least 100 ft (30.5 m) from the following hazards:

(1) Structures or processes that emit sparks or flying brands under ordinary circumstances, such as chimneys, incinerators, flare stacks, or cob burners
(2) Materials or processes of severe fire hazard, such as petroleum processing and storage tanks, explosives manufacturing or storage, and petroleum product pipelines and pumping stations

4.4 Combustible Surfaces with Fixed Protection. Towers with combustible exterior surfaces that are provided with fixed exposure protection in accordance with 5.2.10 shall be permitted to be located closer than 100 ft (30.5 m) from the hazards listed in Section 4.3.

4.5 Noncombustible Exterior Surfaces. Towers with noncombustible exterior surfaces shall be located 40 ft (12 m) or more from the hazards listed in Section 4.3.

4.6 Noncombustible Surfaces with Fixed Protection. Towers with noncombustible exterior surfaces that are provided with fixed interior fire protection installed in accordance with Chapter 5 shall be permitted to be located closer than 40 ft (12 m) from the hazards listed in Section 4.3.

4.7 Combustible Towers on Building Roofs. Combustible water-cooling towers located on building roofs or other locations to which access for manual fire fighting is restricted or difficult shall be provided with a protection system in accordance with Chapter 5.

4.8 Screening.

4.8.1 Open areas or space between a combustible cold-water basin and the ground or roof of a building upon which it is located shall be effectively screened to prevent the accumulation of waste combustible material under the tower and to prevent the use of such areas or space under the tower for the storage of combustible material.

4.8.2 Fire protection shall be permitted to be installed in lieu of screening.

4.9 Fire-Resistant Partition.

4.9.1* A fire-resistant partition for water-cooling towers shall be tested in accordance with ASTM E119 or UL 263.

4.9.2 The partition shall extend from 1 ft (0.3 m) below the operating water level of the cold-water basin to the underside of the fan deck (counterflow towers) or distribution basin (crossflow towers).

Chapter 5 Fire Protection

5.1 General.

5.1.1* Types of Fire Protection Systems. If the fire risk analysis results in Section 4.2, or the conditions of Section 4.7 exist, requiring a fire protection system, that system shall be in accordance with 5.2.2.

5.1.2 Complete Plans and Data Required. A complete plan showing piping arrangement, location of sprinklers, fixed detectors, and operating equipment such as valves and deluge valves, together with hydraulic calculations, water requirements, and water supply information, shall be submitted to the authority having jurisdiction for approval before installation.

5.1.2.1 Plans shall be drawn to scale and shall include the details necessary to indicate clearly all of the equipment and its arrangement.

5.1.2.2 Plans shall show location of new work with relation to existing structures, water-cooling towers, and water supplies.

5.1.2.3 Plans shall include a note listing the types of materials used in the system.

5.2 Fire Protection System Design.

5.2.1 General. Fire protection systems shall be designed, installed, and tested in accordance with NFPA 13.

5.2.2 Types of Systems.

5.2.2.1* The following fire protection systems shall be permitted to be used in counterflow cooling towers:

(1) Wet pipe sprinkler system
(2) Dry pipe sprinkler system
(3) Preaction sprinkler system
(4) Deluge sprinkler system

5.2.2.2* A deluge sprinkler system shall be used in crossflow towers.

5.2.3 Minimum Rate of Application.

5.2.3.1 Under the fan decks of counterflow towers, the rate of application of water shall be 0.5 gpm/ft^2 (20.4 mm/min), including fan opening.

5.2.3.2 Under the fan decks of crossflow towers, the rate of application of water shall be 0.33 gpm/ft^2 (13.45 mm/min), including fan opening.

5.2.3.3 Over the fill areas of crossflow towers, the rate of application of water shall be 0.5 gpm/ft^2 (20.4 mm/min).

5.2.4 Types and Locations of Discharge Outlets.

5.2.4.1* Counterflow Towers.

5.2.4.1.1 The discharge outlets shall be located under the fan deck and fan opening.

5.2.4.1.2 Except under the fan opening, all discharge outlets shall have deflector distances installed in accordance with NFPA 13.

5.2.4.1.3 Closed-head discharge outlets for dry-pipe and preaction systems shall be installed in the upright position only.

5.2.4.2* Crossflow Towers.

5.2.4.2.1 The discharge outlets protecting the plenum area shall be located under the fan deck and in the fan opening.

5.2.4.2.2 Discharge outlets protecting the fill shall be located under the distribution basin on either the louver or drift eliminator side, discharging horizontally through the joist channels.

5.2.4.2.3 Placement and Pressure of Discharge Devices.

5.2.4.2.3.1 Towers with an air travel dimension longer than the maximum allowable for the discharge device being used shall have discharge devices placed on both sides of the fill area in each joist channel.

5.2.4.2.3.2 The pressure at each discharge device shall be adequate to provide protection for half of the length of the fill measured along the air travel.

5.2.4.2.4 Number of Discharge Devices.

5.2.4.2.4.1 Where joist channels are wider than 2 ft (0.6 m), more than one discharge device shall be required per joist channel.

5.2.4.2.4.2 If the discharge device being used is listed for the width of the joist channel being protected, one discharge device per joist channel shall be permitted to be used.

5.2.4.3* Extended Fan Decks. On towers having extended fan decks that completely enclose the distribution basin, the discharge outlets protecting the fill area shall be located over the basin, under the extension of the fan deck.

5.2.4.3.1 These discharge outlets shall be open directional spray nozzles or other approved spray devices arranged to discharge 0.35 gpm/ft^2 (14.26 mm/min) directly on the distribution basin and 0.15 gpm/ft^2 (6.11 mm/min) on the underside of the fan deck extension.

5.2.4.3.2 On towers having extended fan decks that do not completely enclose the hot-water basin, outlets protecting the fill shall be located under the distribution basin in accordance with 5.2.4.2.2.

5.2.4.4 Combustible Fan Decks. For deluge systems using directional spray nozzles in the pendant position, provisions shall be made to protect the underside of a combustible fan deck at a minimum rate of 0.15 gpm/ft^2 (6.11 mm/min), which shall be included as part of the application rate specified in 5.2.3.

5.2.4.5* Water Basin Covers. On film-filled towers that have solid, hot-water basin covers over the complete basin, the discharge outlets protecting the fill area shall be permitted to be located under the basin covers.

5.2.4.5.1 These discharge outlets shall be open directional spray nozzles or other approved devices arranged to discharge 0.50 gpm/ft^2 (20.4 mm/min) into the distribution basin horizontally, with some of the spray splashing up and on the underside of the water basin covers.

5.2.4.5.2 On towers having basin covers that do not completely enclose the hot-water basin, outlets protecting the fill shall be located under the distribution basin in accordance with 5.2.4.2.2.

5.2.5 Pipe, Fittings, and Hangers.

5.2.5.1* Piping shall be installed in accordance with the requirements of NFPA 13.

5.2.5.2* Piping or tubing used within the cooling tower shall be metallic and approved for fire protection use, except as outlined in 5.2.5.2.1.

5.2.5.2.1 Piping or tubing used for pneumatic detection systems shall be permitted to be of other materials suitable for use in a cooling tower environment.

5.2.5.3 Hydraulic calculations shall be made in accordance with NFPA 13.

5.2.5.4 All fittings shall be of a type specifically approved for fire protection use.

5.2.5.4.1 In dry sections of the system piping, which can be exposed to possible fire conditions, ferrous fittings shall be of steel, malleable iron, or ductile iron, except as outlined in 5.2.5.4.2.

5.2.5.4.2 Cast-iron fittings shall be permitted to be used in pneumatic detection piping.

5.2.5.5 Approved, gasketed, groove-type fittings shall be permitted to connect pipe in fire-exposed areas where the fire protection system is operated automatically.

5.2.5.6 Where piping is supported from structural members of a cooling tower, the attachment shall be made so that the structural member is not split or otherwise damaged.

5.2.6 Valves.

5.2.6.1 General.

5.2.6.1.1 Valves shall be installed in accordance with NFPA 13.

5.2.6.1.2 Shutoff valves and automatically operated water control valves, if provided, shall be located as follows:

(1) Outside the fire-exposed area
(2) As close to the cooling tower as possible to minimize the amount of pipe to the discharge device
(3) Where they will be accessible during a fire emergency

5.2.6.2 Manual Release Valve.

5.2.6.2.1 Remote manual release valves, where required, shall be conspicuously located and accessible during a fire emergency.

5.2.6.2.2 Where remote manual release valves are not required, an inspector's test valve shall be provided for each pilot-head-operated system.

5.2.7* Strainers. Strainers shall be required for systems utilizing discharge devices with waterways of less than ⅜ in. (9.5 mm) diameter.

5.2.8* Heat Detectors. Where deluge or preaction systems are used, heat detectors shall be installed and shall be selected from either of the types in 5.2.8.1 or 5.2.8.2.

5.2.8.1 Pilot Line Detection Systems. Where pilot line detection systems are installed for actuation of deluge or preaction systems, heat detectors shall be installed in accordance with 5.2.8.1.1 through 5.2.8.1.4.

5.2.8.1.1 Protection.

5.2.8.1.1.1 Corrosion Protection. Detection equipment shall be protected from corrosion in accordance with Section 5.3.

5.2.8.1.1.2 Protective Canopy. Detection equipment requiring protection from the weather shall be provided with a canopy, hood, or other protection.

5.2.8.1.1.3* Mechanical Damage. Detection equipment shall be located so as to be protected from mechanical damage.

5.2.8.1.1.4 Mounting. Pilot line detectors shall be permitted to be supported by their piping or tubing.

5.2.8.1.2 Selection, Location, and Spacing of Pilot Line Detectors.

5.2.8.1.2.1 The selection, location, and spacing of pilot line detectors for the actuation of fire protection systems shall be in accordance with 5.2.8.1.2.1(A) through 5.2.8.1.2.1(E).

(A) In mechanical-draft towers, pilot line detectors shall be located under the fan deck at the circumference of the fan opening and under the fan opening where necessary to comply with the spacing requirements in 5.2.8.1.2.1(B). *(For extended fan decks, see 5.2.8.2.3.)*

(B) Pilot line detectors shall be spaced not more than 8 ft (2.4 m) apart in any direction including the fan opening. Temperature ratings shall be selected in accordance with operating conditions, but shall be no less than intermediate.

(C) Pilot line detectors shall not be required to be installed under the fan deck area in the fill area of crossflow towers with unenclosed distribution basins.

(D) A pilot line detector shall be provided over each fan drive motor where the motor is located so that it is not within the protected area of the tower.

(E) Specially listed pilot line detection devices specific to water-cooling towers shall be permitted to be used at spacings that have been evaluated and listed in accordance with the following:

(1) Data obtained from field experience
(2) Tests
(3) Engineering surveys
(4) Manufacturer's recommendations
(5) Detectors' listing criteria for water cooling towers
(6) Nature of the hazard being protected
(7) Both normal and abnormal air velocities
(8) Range of anticipated temperatures
(9) Maximum expected rates of temperature change under non-fire conditions
(10) Number and height of structural levels
(11) Effects of environment, including humidity
(12) Presence and magnitude of electromagnetic interference
(13) Presence of obstructions that might retard or mitigate timely detection
(14) Other conditions that might affect the efficacy of the fire detection employed

5.2.8.1.2.2 Detectors shall be located so as to promptly respond to a fire, flammable gas release, or other design condition.

5.2.8.1.2.3 The detection system shall be capable of detecting a fire up to the elevation of the highest level of protected equipment surface.

5.2.8.1.3 Pilot Line Detectors.

5.2.8.1.3.1 Pilot line detectors shall be standard response type unless specifically listed for water-cooling tower applications.

5.2.8.1.3.2 The temperature rating of pilot line detectors shall be selected in accordance with NFPA 13.

5.2.8.1.3.3 Where located under a fan deck or fan deck enclosure, the deflector of a pilot line detector shall be positioned 1 in. (2.54 cm) to 12 in. (30 cm) below an unobstructed fan deck or 1 in. (2.54 cm) to 6 in. (15.24 cm) below the structural members of an obstructed fan deck, but not more than a total of 22 in. (56 cm) below the fan deck.

5.2.8.1.3.4 The obstruction-to-water-distribution rules for automatic sprinklers in NFPA 13 shall not be required to be followed where pilot line detectors are used.

5.2.8.1.3.5 Two or More Systems. Where there are two or more adjacent water spray systems in one area controlled by separate detection systems, the pilot line detectors on each system shall be spaced independently.

5.2.8.1.4 Arrangement and Supervision of Pneumatic and Hydraulic Systems. Pneumatically and hydraulically operated systems shall be supervised in a manner such that failure will result in positive notification of the abnormal condition, unless the failure results in operation of the water spray system.

5.2.8.2 Electrical Heat Detection Systems. Where electrical detection systems are installed for actuation of deluge or preaction systems, heat detectors shall be installed in accordance with the applicable sections of *NFPA 72*.

5.2.8.2.1 In mechanical-draft towers, electrical heat detectors shall be located under the fan deck at the circumference of the fan opening and under the fan opening where necessary to comply with the spacing requirements of 5.2.8.2.2 through 5.2.8.2.2.2. *(For extended fan decks, see 5.2.8.3.)*

5.2.8.2.2* Electrical fixed-temperature detectors shall be spaced not more than 8 ft (2.4 m) apart in any direction including the fan opening.

5.2.8.2.2.1 Temperature ratings shall be selected in accordance with operating conditions, but shall be no less than intermediate.

5.2.8.2.2.2 Electrical fixed-temperature detectors shall not be required to be installed under the fan deck area of crossflow towers with unenclosed distribution basins.

5.2.8.2.3 On towers having extended fan decks that completely enclose the distribution basin, electrical heat detectors shall be located under the fan deck extension in accordance with standard, indoor-spacing rules for the type detectors used in accordance with *NFPA 72*.

5.2.8.2.3.1 Where the fan deck extension is 16 ft (4.9 m) or less and this dimension is the length of the joist channel, then only one row of detectors centered on and at right angles to the joist channels shall be required. Spacing between detectors shall be in accordance with *NFPA 72*.

5.2.8.2.3.2 On towers having extended fan decks that do not completely enclose the hot-water basin, electrical heat detectors shall not be required under the fan deck extension.

5.2.8.3 Where electrical heat detectors are inaccessible during tower operation, an accessible test detector shall be provided for each detection zone.

5.2.8.4 Electrical heat detector components exposed to corrosive vapors or liquids shall be protected by materials of construction or by protective coatings applied by the equipment manufacturer.

5.2.9 Protection for Fan Drive Motor.

5.2.9.1 A sprinkler or spray nozzle shall be provided over each fan drive motor where the motor is located so that it is not within the protected area of the tower.

5.2.9.2 Where a preaction or deluge system is used, the detection system shall be extended to cover the motor.

5.2.9.3 Provision shall be made to interlock the fan motors with the fire protection system so that the cooling tower fan motors are stopped in the cell(s) for which the system is actuated.

5.2.9.4 Where the continued operation of the fans is vital to the process, a manual override switch shall be permitted to be provided to reactivate the fan when it is determined that there is no fire.

5.2.10 Exposure Protection.

5.2.10.1 Where any combustible exterior surfaces of a tower, including the fan deck and distribution basins, are less than 100 ft (30.5 m) from significant concentrations of combustibles such as structures or piled material, the combustible exposed surfaces of the tower shall be protected by an automatic water spray system.

5.2.10.2 Systems for exterior protection shall be designed with the same attention and care as interior systems.

5.2.10.2.1 Pipe sizing shall be based on hydraulic calculations.

5.2.10.2.2 Water supply and discharge rate shall be based on a minimum 0.15 gpm/ft^2 (6.11 mm/min) for all protected surfaces.

5.2.11 Suppression Design. The design and installations shall comply with the applicable sections of NFPA 13.

5.3 Corrosion Protection.

5.3.1* Piping, fittings, hangers, braces, and attachment hardware including fasteners shall be hot-dipped galvanized steel in accordance with ASTM A153/A153M, or other materials having a superior corrosion resistance.

5.3.1.1 Exposed pipe threads and bolts on fittings shall be protected against corrosion.

5.3.1.2 All other components shall be corrosion resistant or protected against corrosion by a coating.

5.3.2* Wax-type coatings shall not be used on devices without fusible elements.

5.3.3* Special care shall be taken in the handling and installation of wax-coated or similar sprinklers to avoid damaging the coating.

5.3.3.1 Corrosion-resistant coatings shall not be applied to the sprinklers by anyone other than the manufacturer of the sprinklers.

5.3.3.2 In all cases, any damage to the protective coating occurring at the time of installation shall be repaired at once using only the coating of the manufacturer of the sprinkler in an approved manner, so that no part of the sprinkler is exposed after the installation has been completed.

5.4* Hydrant Protection. Hydrants shall not be located less than 40 ft (12.2 m) from towers.

5.5* Standpipe Protection. Towers with any combustible construction located on a building 50 ft (15.3 m) or more in height shall be provided with Class III standpipe protection with hose connections within 200 ft (61 m) of all parts of the tower.

5.5.1 Sufficient hose shall be provided to reach all parts of the tower.

5.5.2 Provision shall be made for completely draining all exposed standpipe lines during winter.

5.5.3 Hose equipment at each standpipe hose connection on the roof shall be protected from the weather in a cabinet or enclosure in accordance with NFPA 14.

5.6 Water Supply.

5.6.1 Deluge Systems.

5.6.1.1* Where all cells of a cooling tower are protected by a single deluge system, the water supply shall be adequate to supply all discharge outlets on that system.

5.6.1.2* Where two or more deluge systems are used to protect a cooling tower and fire-resistant partitions are not provided between the deluge systems, the water supply shall be adequate to supply all discharge outlets in the two most hydraulically demanding adjacent systems.

5.6.1.3* Where two or more deluge systems are separated by fire-resistant partitions, the water supply shall be adequate to supply all discharge outlets in the single most hydraulically demanding system.

5.6.1.4* On towers having extended fan decks that completely enclose the distribution basin, one of the following options shall be employed:

(1) The water supply shall be designed for all deluge systems.
(2) Heat barriers shall be installed under the extended fan deck to separate deluge system zones in order to prevent the total number of deluge systems operating from exceeding the number of deluge systems for which the water supply was designed. Heat barriers shall extend from the fan deck structure to the distribution basin dividers.

5.6.2 Wet, Dry, and Preaction Systems.

5.6.2.1* Where each cell of the cooling tower is separated by a fire-resistant partition, the water supply shall be adequate to supply all discharge outlets in the hydraulically most demanding single cell.

5.6.2.2* Where fire-resistant partitions are not provided between each cell of a cooling tower, the water supply shall be adequate to supply all discharge outlets in the two most hydraulically demanding adjoining cells.

5.6.3 Hose Streams. Water supplies shall be sufficient to include a minimum of 500 gpm (1892.5 L/min) for hose streams in addition to the sprinkler requirements.

5.6.4 Duration. A water supply adequate for at least a 2-hour duration shall be provided for the combination of the water supply specified in 5.6.1 or 5.6.2, plus the hose stream demand specified in 5.6.3.

5.7* Lightning Protection. Lightning protection, where provided, shall be installed in accordance with the provisions of NFPA 780.

5.8 Earthquake Protection. Where provided, earthquake-resistant construction shall be in accordance with applicable sections of NFPA 13.

Chapter 6 Electrical Equipment and Wiring

6.1 Installation. Installation of all electrical equipment and wiring pertaining to water-cooling towers shall be in accordance with *NFPA 70*.

6.2* Overcurrent Protection. Electric motors that are driving fans shall be provided with overcurrent protection devices as mandated by *NFPA 70*.

6.3 Stop Fan. A remote fan motor switch shall be provided to stop the fan in case of fire.

6.4 Interlock. When a fire protection system is installed, provisions shall be made to interlock the fan motors with the fire protection system as set forth in Chapter 5.

6.5 Vibration-Controlled Switch. A listed, automatic, vibration-controlled switch shall be provided to automatically shut down fan motors.

Chapter 7 Internal Combustion Engine–Driven Fans

7.1 Internal Combustion Engines.

7.1.1 Electric motors or steam turbines shall be the preferred drives to operate fans on water-cooling towers.

7.1.2 Where neither electric motor nor steam turbines are available, internal combustion engines shall be permitted to be used, provided they are installed, used, and maintained in accordance with NFPA 37.

Chapter 8 Operating Features, Maintenance, and Access

8.1 Housekeeping. Areas around towers located on the ground shall be kept free of grass, weeds, brush, or combustible waste materials.

8.2 Smoking.

8.2.1 Smoking shall not be permitted on or adjacent to any cooling tower of combustible construction.

8.2.2 Signs stating the provisions of 8.2.1 shall be posted and maintained, and this regulation shall be strictly enforced.

8.3 Mechanical Inspection. Forced- and induced-draft towers in continuous operation shall be checked for excessive heating in motors and for excessive fan vibration.

8.4 Inspection Frequency.

8.4.1 At least semiannually, the fan assemblies, including the motors and speed reducers, shall be checked, both during operation and when shut down, for excessive wear or vibration, improper lubrication, corrosion, or other factors that could result in failure.

8.4.2 Where conditions require it, corrective action shall be taken.

8.5 Welding and Cutting. Where work on the tower requires welding or cutting, it shall be done in accordance with NFPA 51B.

8.6 Down Time.

8.6.1* All automatic fire protection on the tower shall be operable during periods when the towers are shut down for repairs or other reasons.

8.6.2* Where the tower does not have automatic fire protection, special protection shall be provided until the tower is back in service.

8.7 Access.

8.7.1 Access to the tops of water-cooling towers for fire fighting and maintenance shall be provided by an approved stairway or ladder.

8.7.2 Towers in excess of 120 ft (37 m) in any dimension shall be provided with not less than two means of access remote from each other.

8.8 Lockout.

8.8.1 Motors, speed reduction units, and drive shafts shall be accessible for servicing and maintenance.

8.8.2 Lockout or tagout of fan equipment shall be conducted when maintenance work is being performed in the vicinity of fans.

8.9 Temporary Supports. After maintenance work is completed, all scaffolding, boards, temporary supports, and other temporary materials shall be removed from the tower.

8.10 Fire Protection Systems Inspection, Testing, and Maintenance. Fire protection systems installed in accordance with this standard shall be inspected, tested, and maintained in accordance with NFPA 25.

Annex A Explanatory Material

Annex A is not a part of the requirements of this NFPA document but is included for informational purposes only. This annex contains explanatory material, numbered to correspond with the applicable text paragraphs.

A.1.1 This standard does not apply any more or less strictly to factory-assembled units than did earlier revisions. Because these units have typically been steel frame/structure with PVC fill, the protection requirements should be evaluated in accordance with Section 4.2, with item (2) being specifically noted. In all cases, Section 4.2 should be reviewed for making the determination with regard to the installation of fire suppression systems. In some cases, no fire suppression is required.

The fire record of water-cooling towers indicates a failure to recognize the extent or seriousness of the potential fire hazard of these structures either while in operation or when temporarily shut down. Water-cooling towers of combustible construction, especially those of the induced-draft type, present a potential fire hazard even when in full operation because of the existence of relatively dry areas within the towers.

A significant percentage of fires in water-cooling towers of combustible construction are caused by ignition from outside sources such as incinerators, smokestacks, or exposure fires. Fires in water-cooling towers can create an exposure hazard to adjacent buildings and processing units. Therefore, distance separation from buildings and sources of ignition or the use of noncombustible construction are primary considerations in preventing these fires.

Ignition within these structures can be caused by welding or cutting operations, smoking, overheated bearings, electrical failures, and other heat- or spark-producing sources.

Fires have also occurred during the construction of water-cooling towers. Measures should be taken during construction to prevent the accumulation of combustible waste materials such as wood borings, shavings, scrap lumber, or other easily ignited materials. "No Smoking" regulations and strict control of welding and other heat- or spark-producing operations should be enforced. Wetting down combustible portions of the tower during idle periods of construction is a good fire prevention practice.

Where cooling water is supplied to heat exchangers that are used for cooling flammable gases or liquids or combustible liquids, and where the cooling water pressure is less than that of the material being cooled, an unusual hazard to the cooling tower can be created by the return of the flammables or combustibles to the cooling tower water distribution system.

A.3.2.1 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

A.3.2.2 Authority Having Jurisdiction (AHJ). The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A.3.2.4 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A.3.3.2 Cell. Each cell can have one or more fans or stacks and one or more distribution systems. For the purposes of this standard, a cell within a hyperbolic tower is considered the area bounded by fire-resistant partitions.

A.3.3.4 Cooling Tower. See Figure B.1(a).

A.3.3.4.1 Counterflow. See Figure B.1(d).

A.3.3.4.2 Crossflow. See Figure B.1(e).

A.3.3.4.5 Mechanical-Draft. When the fans or blowers are at the air inlet, the tower is considered forced-draft. When the fans or blowers are at the air exit, the tower is considered induced-draft. *[See Figure B.1(c).]*

A.3.3.4.6 Natural-Draft. Natural-draft towers contain no fans or blowers. *[See Figure B.1(b).]*

A.3.3.6 Fire-Resistant Partition. Examples of some types of construction in a wood-framed tower that meet this requirement are ½ in. (12.7 mm) cement board, ½ in. (12.7 mm) plywood, or ¾ in. (19.1 mm) tongue-and-groove boarding where installed on both sides of wood studs. Other types of assemblies, both partition and frame, should be tested in accordance with ASTM E119 or UL 263.

Occasionally, the water level is lowered or the cold-water basin is emptied (e.g., for tower maintenance). Where the tower is empty for an extended period of time, the fire partition should be extended to the bottom of the cold-water basin, for example, by installing a temporary extension. The temporary fire partition should remain in place, except where it interferes with the maintenance activity in a single cell, until the tower is returned to service and the water level in the basin is returned to normal.

A.4.2 No standard can be promulgated that guarantees the elimination of fires in water-cooling towers. Technology in this area is under constant development and is reflected in revisions to this standard. The user of this standard should recognize the complexity of fire protection requirements for water-cooling towers. Therefore, the designer is cautioned that this standard is not a design handbook. This standard does not do away with the need for the engineer or for competent engineering judgment. It is intended that a designer, capable of applying more complete and rigorous analysis to special or unusual problems, has latitude in the development of such designs. In such cases, the designer is responsible for demonstrating the validity of the approach.

Fire experience for mechanical-draft towers does not indicate the general need for automatic fire protection systems. However, exposure protection provided as required by 5.2.10 might be necessary.

A.4.2(2) Several fire tests can be used to evaluate the fire risk related to water-cooling tower materials. The most suitable tests are those that demonstrate low fire risk where tested in a configuration that approximates the large scale of the installation. Tests such as ASTM E136 and ASTM E84 have limitations. The test methods do not duplicate the larger extent of the hazard in its final installation and are not necessarily suitable or generally satisfactory for materials that soften, flow, or melt under fire conditions.

A.4.2(8) Piping arrangements, system capacities, and supervisory air pressures should be designed such that the time for water delivery to the most remote discharge device is minimized. For all water suppression systems using detection, the detection system should be designed to cause actuation of the special water control valve within 20 seconds under expected exposure conditions (*see* NFPA 15).

A.4.9.1 Fire-resistant partition testing for water-cooling towers should reflect their intended purpose (bearing or non-bearing). ASTM E119 or UL 263 sets out two test judgment criteria. Both judgment criteria should be met.

A.5.1.1 The use of antifreeze sprinkler systems in water-cooling towers is not recommended. While in theory this type of system would function, the use of antifreeze systems in water-cooling towers presents problems not encountered in usual antifreeze applications.

Due to the inaccessibility of the piping during normal operation of the cooling tower, it is almost impossible to do any maintenance work or to make routine inspections. The corrosion problem can be quite serious in water-cooling towers, and leaks in the system do not readily become apparent. These leaks would result in loss of the antifreeze solution and could result in freezing of the system.

Local ordinances in many areas prohibit the use of these systems.

A.5.2.2.1 Counterflow design configurations lend themselves to use of open- or closed-orifice fire protection systems. A deluge system provides a higher degree of protection where water supplies are adequate. In climates that are subject to freezing temperatures, a dry pipe, preaction, or deluge system minimizes the possibility of failure due to pipes freezing.

A.5.2.2.2 The crossflow design is such that it is difficult to locate sprinklers in the most desirable spots for both water distribution and heat detection. This situation is best addressed by using a deluge system.

A.5.2.4.1 Figure A.5.2.4.1(a) through Figure A.5.2.4.1(d) show typical plan and section views of fire protection systems in counterflow water-cooling towers. For the requirement to screen area beneath the tower in Figure A.5.2.4.1(b), see 4.8.1.

A.5.2.4.2 Figure A.5.2.4.2(a) through Figure A.5.2.4.2(d) show typical plan and section views of fire protection systems in crossflow water-cooling towers.

A.5.2.4.3 Location of the nozzle relative to surfaces to be protected should be determined by the particular nozzle's discharge characteristics. Care should also be taken in the selection of nozzles to obtain waterways not easily obstructed by debris, sediment, sand, and so forth, in the water. *[See Figure A.5.2.4.3(a) and Figure A.5.2.4.3(b).]*

A.5.2.4.5 Figure A.5.2.4.5 shows a detail of the sprinklers and target nozzles for an enclosed distribution basin in a crossflow tower.

A.5.2.5.1 In towers where vibration is anticipated to cause movement of the fire protection system, resulting in wear of water piping, detection piping, or tubing at the hangers, it is necessary to install vibration absorbers between the hangers and the pipe.

Special consideration should be given to the support of detection piping or tubing due to its small diameter. Thin-wall or nonmetallic pipe or tubing usually requires close spacing of hangers for adequate support.

A.5.2.5.2 Where plastic piping or tubing is used for pneumatic detection systems, consideration should be given to the effects of ultraviolet radiation.

A.5.2.7 See NFPA 15 for further details.

FIGURE A.5.2.4.1(c) Plan View, Typical Deluge or Dry-Pipe Fire Protection Arrangement for Counterflow Towers.

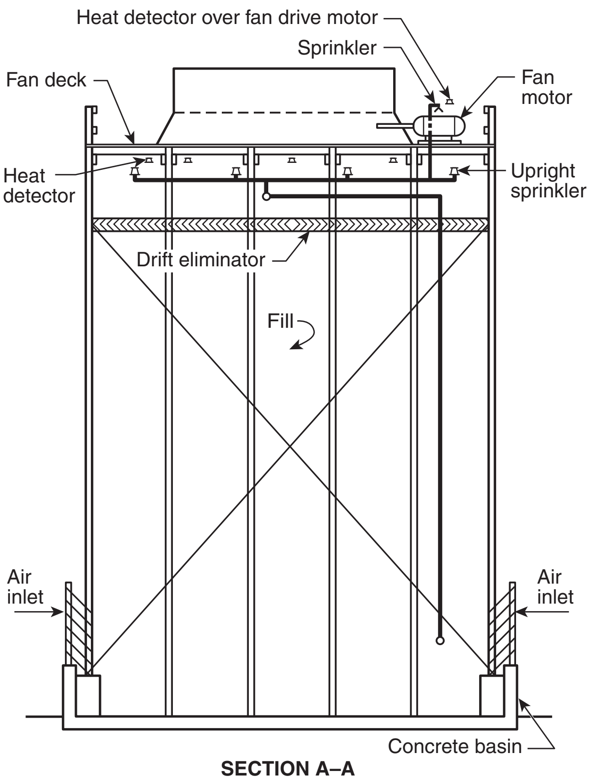

FIGURE A.5.2.4.1(d) Section View, Typical Deluge or Dry-Pipe Fire Protection Arrangement for Counterflow Towers.

A.5.2.8 Over the years, rate-of-rise detection systems were installed for the actuation of deluge or preaction systems. Some of these systems are still in the field and are being maintained in accordance with their listing. The design criterion was that these rate-of-rise detectors were spaced not more than 15 ft (4.6 m) apart in any direction. In pneumatic-type systems, for detectors inside the tower, these detectors were to be no more than one detector for each mercury check in towers operating in cold climates, and two detectors for each mercury check in towers used during the warm months only or year-round in warm climates. Also, these detectors were to be no more than four detectors for each mercury check where the detectors are located outside the tower.

A.5.2.8.1.1.3 Consideration should be given to the protection of the detection system in areas subject to earthquake damage. Some guidance on this topic is provided in NFPA 13.

A.5.2.8.2.2 Due to the extremely humid atmosphere and potentially corrosive conditions in water-cooling towers, it is very difficult to maintain electrical detection equipment. Experience has shown that even with weatherproof equipment and wiring practices, an electrical system malfunctions frequently. Therefore, the information in the subparagraphs of this section is based on the use of detectors operating on pneumatic or hydraulic principles.

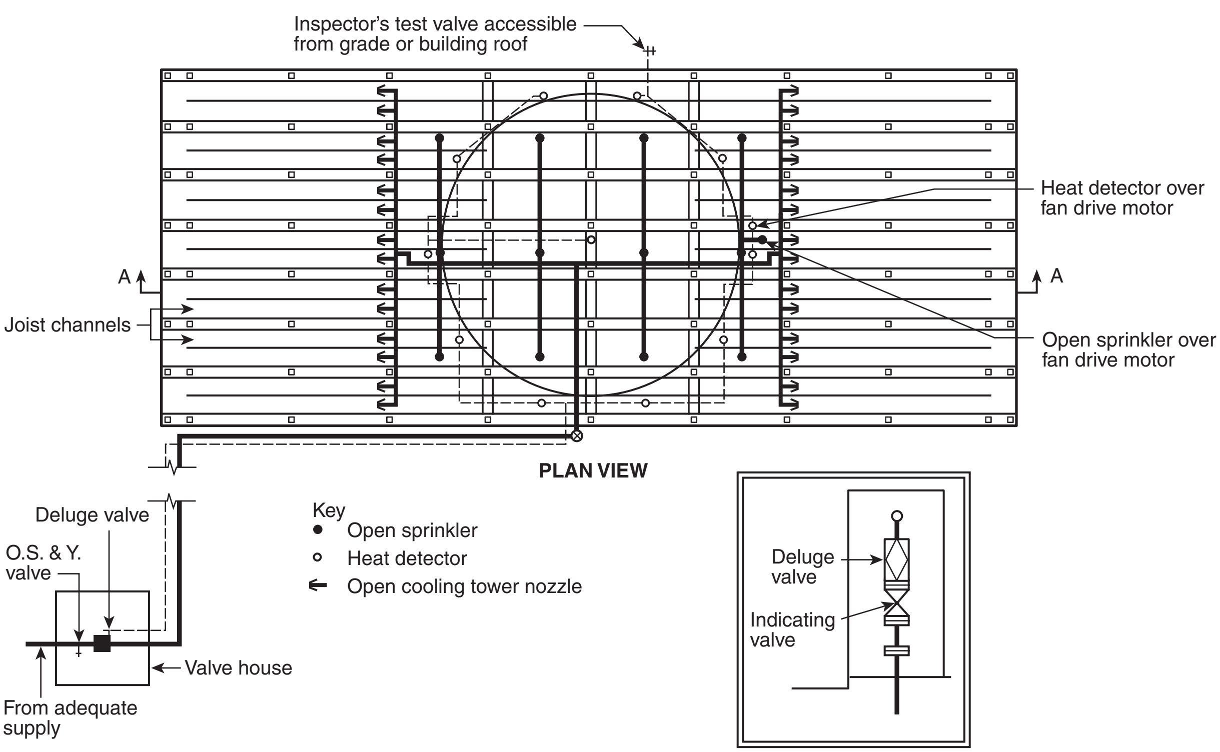

FIGURE A.5.2.4.2(a) Plan View, Typical Deluge Fire Protection Arrangement for Crossflow Towers.

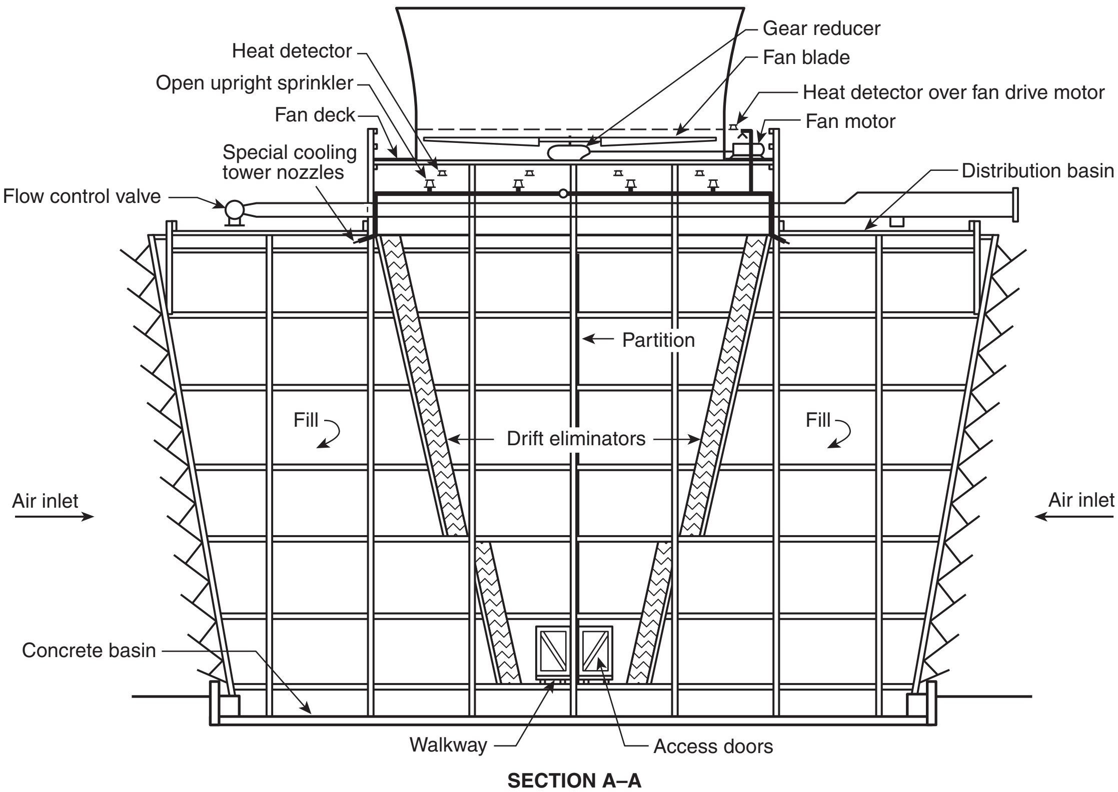

FIGURE A.5.2.4.2(b) Section View, Typical Deluge Fire Protection Arrangement for Crossflow Towers.

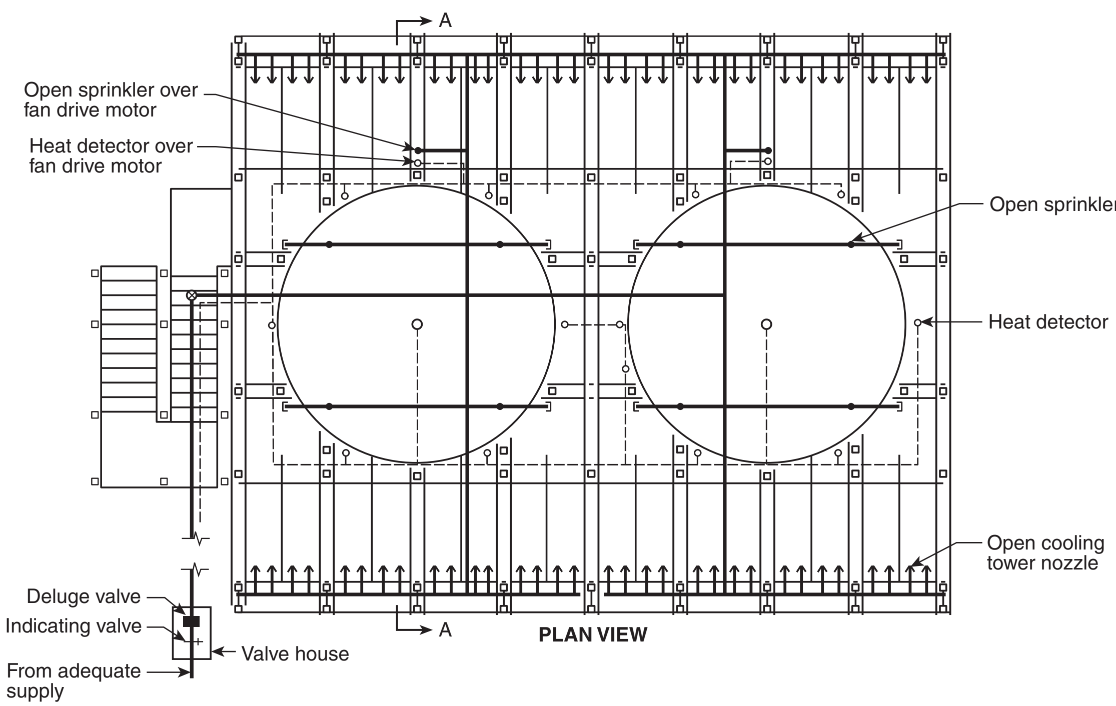
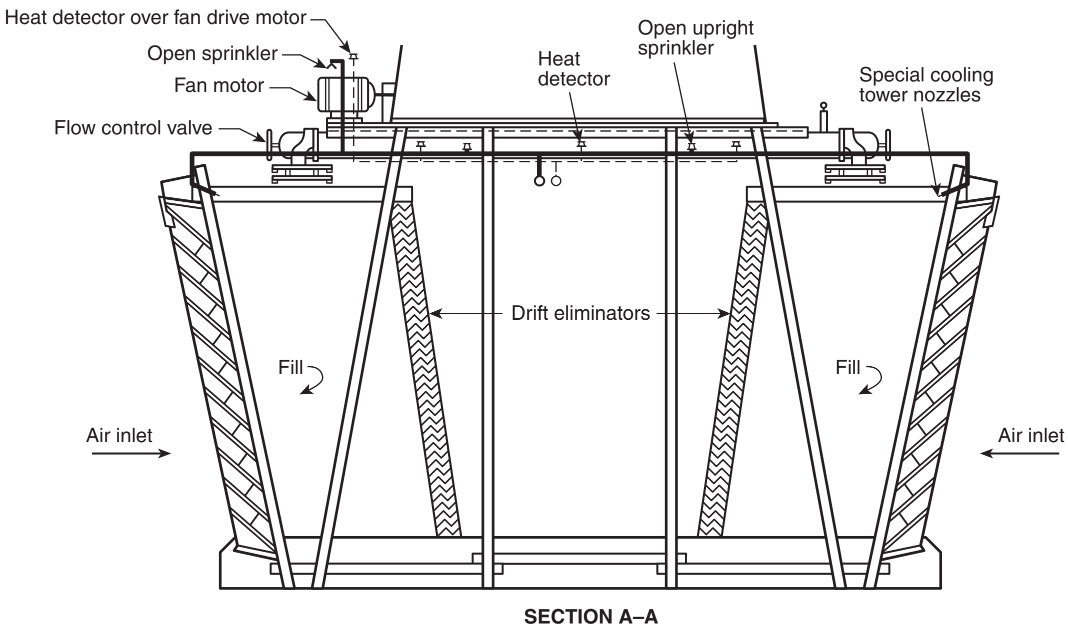


Note: Where air seal boards prevent installation of cooling tower nozzles on drift eliminator side of fill, this nozzle location should be used.

FIGURE A.5.2.4.2(c) Plan View, Typical Deluge Fire Protection Arrangement for Multicell Crossflow Towers.



Note: Where air seal boards prevent installation of cooling tower nozzles on drift eliminator side of fill, this nozzle location should be used.

FIGURE A.5.2.4.2(d) Section View, Typical Deluge Fire Protection Arrangement for Multicell Crossflow Towers.

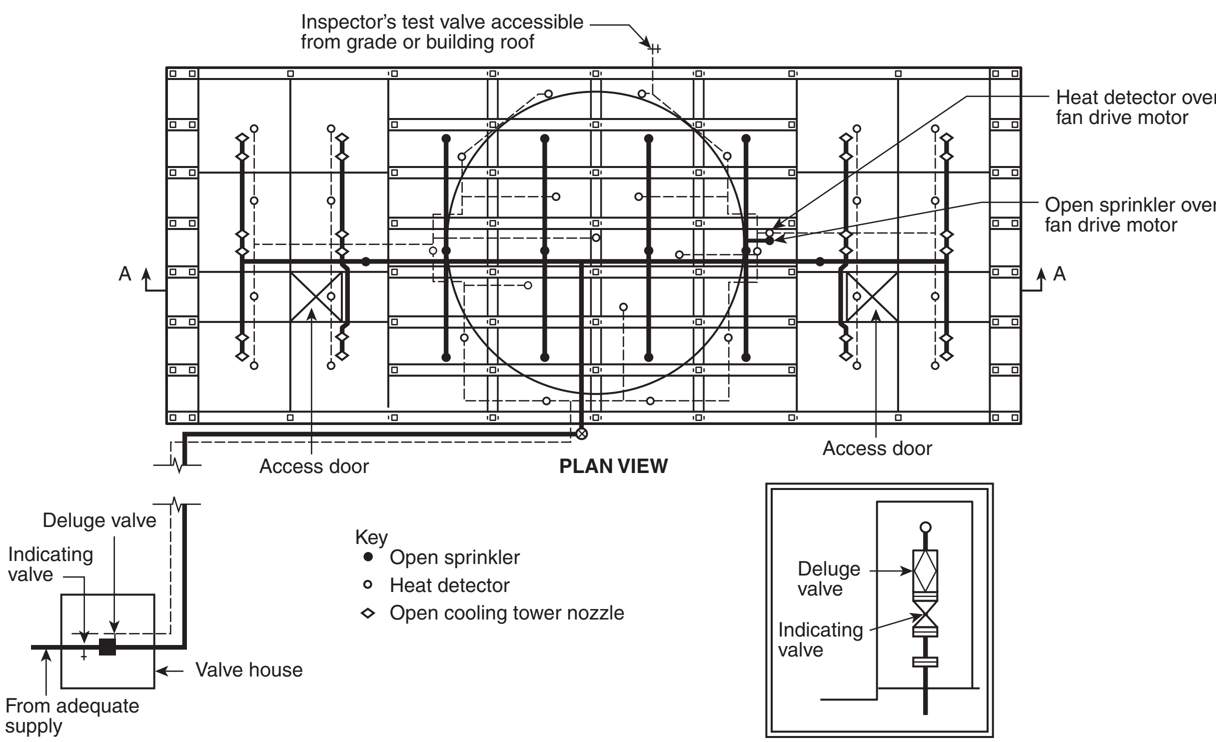


FIGURE A.5.2.4.3(a) Plan View, Typical Deluge Fire Protection Arrangement for Crossflow Towers with Completely Enclosed Distribution Basins.

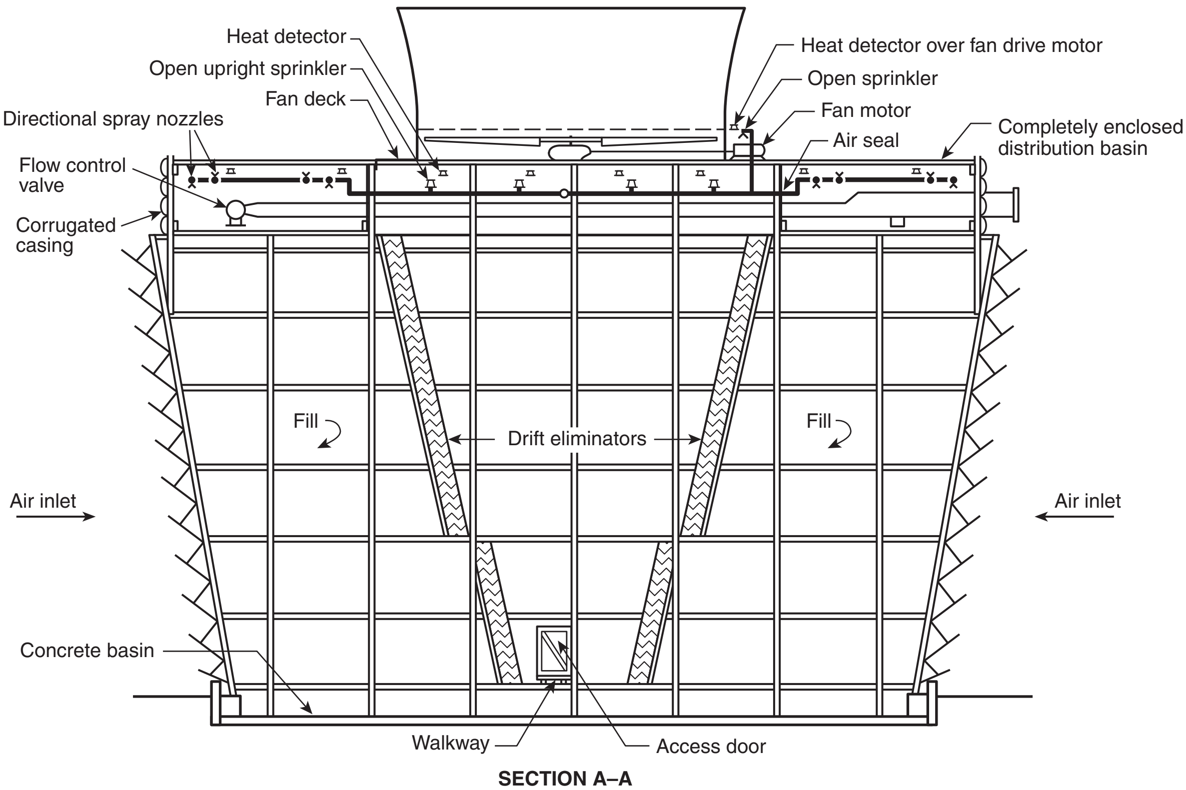

FIGURE A.5.2.4.3(b) Section View, Typical Deluge Fire Protection Arrangement for Crossflow Towers with Completely Enclosed Distribution Basins.

A.5.3.1 Corrosion of exposed pipe threads and bolts on fittings is a concern. Therefore, care should be taken to ensure that corrosion protection is as equivalent to hot-dipped galvanized steel as possible. Experience has shown that cadmium-plated components corrode at an accelerated rate compared to hot-dipped galvanized components.

If circulating tower water quality has the following characteristics, an upgrade of hot-dipped galvanized sprinkler components should be considered:

(1) Calcium, as $CaCO_3$ <50 ppm
(2) Chloride >450 ppm as Cl^- (750 ppm as NaCl)
(3) pH <6.5
(4) pH >9.0
(5) Hot water temperature >140°F (60°C)

Other unusual water uses include geothermal power, paper processing, and Stretford process, each of which can require component material upgrade.

A.5.3.2 Approved discharge devices are made of nonferrous material and are corrosion-resistant to normal atmospheres. Some atmospheres require special coatings on the discharge devices.

A.5.3.3 Corrosion attacks the exposed metal and, in time, creeps under the wax coating.

A.5.4 Hydrant protection should be provided within 200 ft (61 m) of all parts of towers having combustible construction and located on the ground or on buildings less than 50 ft (15.3 m) in height. A hose house and standard hose house equipment should be provided at each hydrant. *(See NFPA 24 for further details.)*

A.5.5 Standpipes should preferably be located in stair towers. If located on an open roof, they should not be closer than 40 ft (12.2 m) to the cooling tower. For a definition of Class III standpipe protection, see NFPA 14.

A.5.6.1.1 Where a single deluge system protects an entire water-cooling tower, regardless of the number of cells, the water supply needs to be based on the entire deluge system coverage. *(See Figure A.5.6.1.1.)*

A.5.6.1.2 Without fire-resistant partitions between cells, the worst-case situation involves the most demanding adjoining cells. *(See Figure A.5.6.1.2.)*

A.5.6.1.3 Deluge systems separated by fire-resistant partitions can be treated independently as worst-case water supply situations. *(See Figure A.5.6.1.3.)*

A.5.6.1.4 Acceptable materials are ⅜ in. (9.5 mm) plywood or $\frac{3}{16}$ in. (4.8 mm) asbestos cement board on one side of studs.

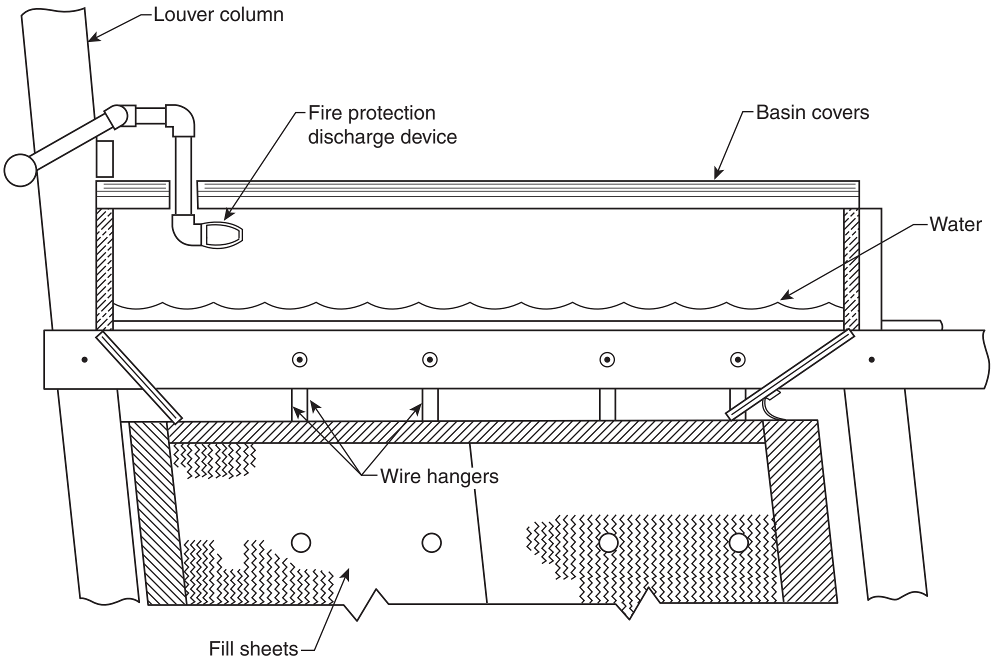

FIGURE A.5.2.4.5 Typical Deluge Fire Protection Arrangement for Crossflow Towers with Covers Completely Enclosing Distribution Basins.

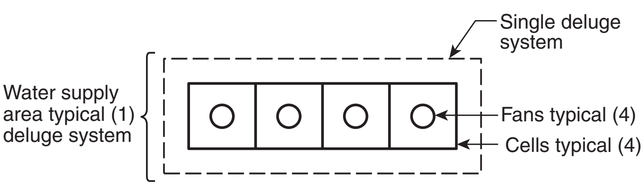

FIGURE A.5.6.1.1 Single Deluge System.

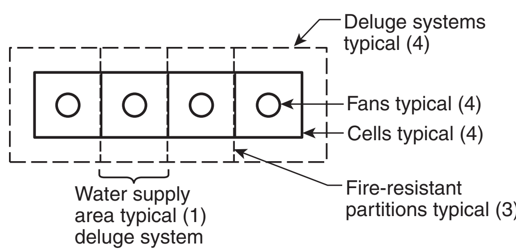

FIGURE A.5.6.1.3 Multiple Deluge Systems.

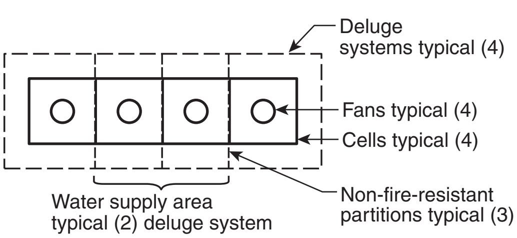

FIGURE A.5.6.1.2 Multiple Deluge Systems with No Fire-Resistant Partitions.

A.5.6.2.1 Water-cooling towers with each cell separated by a fire-resistant partition and protected by wet, dry, or preaction system(s) should have the water supply based on the most demanding individual cell. *(See Figure A.5.6.2.1.)*

A.5.6.2.2 Without fire-resistant partitions between cells, the worst-case situation involves the most demanding adjoining cells. *(See Figure A.5.6.2.2.)*

A.5.7 Towers located on roofs of buildings in certain geographical locations can be particularly susceptible to lightning damage.

A.6.2 Motors should be totally enclosed to protect them from dirt or moisture and to prevent sparks from reaching adjacent combustible construction.

A.8.6.1 During periods when combustible water-cooling towers are shut down for repairs or other reasons, the towers become particularly susceptible to ignition as the wood dries out.

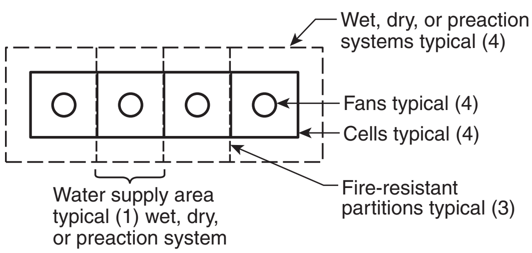

FIGURE A.5.6.2.1 Multiple Wet, Dry, or Preaction Systems with Fire-Resistant Partitions.

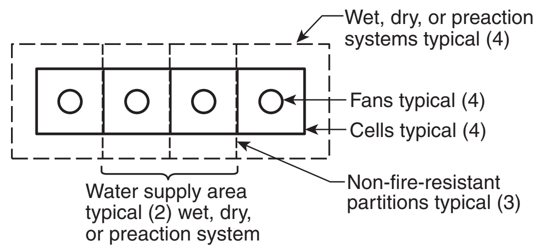

FIGURE A.5.6.2.2 Multiple Wet, Dry, or Preaction Systems with No Fire-Resistant Partitions.

A.8.6.2 Examples of special protection are watch service or intermittent wetting, or both.

Annex B Water-Cooling Tower Types

This annex is not a part of the requirements of this NFPA document but is included for informational purposes only.

B.1 Figure B.1(a) through Figure B.1(e) represent typical configurations of the many types of water-cooling towers.

NFPA® 220

Standard on

Types of Building Construction

2015 Edition

This edition of NFPA 220, *Standard on Types of Building Construction*, was prepared by the Technical Committee on Building Construction. It was issued by the Standards Council on April 29, 2014, with an effective date of May 19, 2014, and supersedes all previous editions.

This edition of NFPA 220 was approved as an American National Standard on May 19, 2014.

Origin and Development of NFPA 220

In 1952, the Committee on Building Construction secured tentative adoption of NFPA 220, *Standard on Types of Building Construction*, at the NFPA Annual Meeting. At the 1954 NFPA Annual Meeting, revisions of the 1952 tentative text were adopted by the Association, and in 1955 minor revisions also were acted on favorably. A new definition of *noncombustibility* and editorial changes in the description of the fire resistance rating of structural members (under the definition of *fire-resistive construction*) were adopted at the 1956 NFPA Annual Meeting on the recommendation of the Committee on Building Construction.

In 1958, with the development of the use of plastics in building construction, recommendations on the types of standard fire tests to be used in evaluating the fire safety of these materials were adopted and inserted in the appendix.

In 1961, an appendix was adopted to furnish a guide to NFPA committees, regulatory officials, and others that addressed the classification of air-supported structures.

In 1975, a more fundamental definition of *noncombustible* was added, including the introduction of a definition of the term *limited-combustible,* based on potential heat value limitations and more generalized definitions for types of building construction.

In 1979, the standard was extensively rewritten to introduce the nomenclature related to construction Type I through Type V, which included parenthetically placed hourly fire resistance designations of the structural components.

The 1985 edition included the addition of a new Chapter 4, which provided referenced publications whose use is mandated within this standard. The 1992 and 1995 editions provided changes in technical terminology as well as changes to increase the user-friendliness of the standard.

The 1999 edition implemented a number of relatively minor changes, including the addition of several new definitions, the addition of a new requirement pertaining to exterior non–load-bearing walls, and a new provision concerning the use of heavy timber exterior walls.

In the 2006 edition, NFPA 220 became an extract document of *NFPA 5000®*, Section 7.2. At the request of the Standards Council, the new edition provided users with a stand-alone set of requirements for construction types and fire resistance ratings of structural elements.

The 2009 edition provided updates to the extracted text that was sourced back to *NFPA 5000* and NFPA 90A. These revisions included updates to the test protocols used to establish flame spread/smoke developed index values, modified criteria for materials used in air handling plenum spaces, and provided recognition of the new criteria used to determine building height and grade geometries.

The 2012 edition was updated to reflect changes in *NFPA 5000* and NFPA 90A. Revisions included updates to the requirements for plenums and noncombustible materials.

The 2015 edition has been revised to include new requirements for limited and noncombustible materials. Referenced publications have also been updated.

This list represents the membership at the time the Committee was balloted on the final text of this edition. Since that time, changes in the membership may have occurred. A key to classifications is found at the back of the document.

NOTE: Membership on a committee shall not in and of itself constitute an endorsement of the Association or any document developed by the committee on which the member serves.

Committee Scope: This committee shall have primary responsibility for documents on the selection and design of types of building construction, exterior walls, building height and area, firewalls, and fire barrier walls, as they relate to the protection of life and property from fire. For the processing of *NFPA 5000*, Chapter 7, and Sections 8.3 and 8.4, this committee reports directly to the *NFPA 5000* TCC; whereas, for the processing of NFPA 220 and NFPA 221, this committee does not report to the *NFPA 5000* TCC.

IMPORTANT NOTE: This NFPA document is made available for use subject to important notices and legal disclaimers. These notices and disclaimers appear in all publications containing this document and may be found under the heading "Important Notices and Disclaimers Concerning NFPA Documents." They can also be obtained on request from NFPA or viewed at www.nfpa.org/disclaimers.

NOTICE: An asterisk (*) following the number or letter designating a paragraph indicates that explanatory material on the paragraph can be found in Annex A.

A reference in brackets [ ] following a section or paragraph indicates material that has been extracted from another NFPA document. As an aid to the user, the complete title and edition of the source documents for extracts in mandatory sections of the document are given in Chapter 2 and those for extracts in informational sections are given in Annex B. Extracted text may be edited for consistency and style and may include the revision of internal paragraph references and other references as appropriate. Requests for interpretations or revisions of extracted text shall be sent to the technical committee responsible for the source document.

Information on referenced publications can be found in Chapter 2 and Annex B.

Chapter 1 Administration

1.1* Scope. This standard defines types of building construction based on the combustibility and the fire resistance rating of a building's structural elements. Fire walls, nonbearing exterior walls, nonbearing interior partitions, fire barrier walls, shaft enclosures, and openings in walls, partitions, floors, and roofs are not related to the types of building construction and are regulated by other standards and codes, where appropriate.

1.2 Purpose. This standard provides definitions for standard types of building construction.

1.3 Application. (Reserved)

1.4 Retroactivity.

1.4.1 The provisions of this standard reflect a consensus of what is necessary to provide an acceptable degree of protection from the hazards addressed in this standard at the time the standard was issued.

1.4.2 Unless otherwise specified, the provisions of this standard shall not apply to facilities, equipment, structures, or installations that existed or were approved for construction or installation prior to the effective date of the standard. Where specified, the provisions of this standard shall be retroactive.

1.4.3 In those cases where the authority having jurisdiction determines that the existing situation presents an unacceptable degree of risk, the authority having jurisdiction shall be permitted to apply retroactively any portions of this standard deemed appropriate.

1.4.4 The retroactive requirements of this standard shall be permitted to be modified if their application clearly would be impractical in the judgment of the authority having jurisdiction, and only where it is clearly evident that a reasonable degree of safety is provided.

1.5 Equivalency.

1.5.1 Nothing in this standard is intended to prevent the use of systems, methods, or devices of equivalent or superior quality, strength, fire resistance, effectiveness, durability, and safety over those prescribed by this standard.

1.5.2 Technical documentation shall be submitted to the authority having jurisdiction to demonstrate equivalency. The system, method, or device shall be approved for the intended purpose by the authority having jurisdiction.

1.6 Units.

1.6.1 SI Units. Metric units in this standard are in accordance with the modernized metric system known as the International System of Units (SI).

1.6.2 Primary and Equivalent Values. If a value for a measurement as given in this standard is followed by an equivalent value in other units, the first stated value shall be regarded as the requirement. A given equivalent value might be approximate.

Chapter 2 Referenced Publications

2.1 General. The documents or portions thereof listed in this chapter are referenced within this standard and shall be considered part of the requirements of this document.

2.2 NFPA Publications. National Fire Protection Association, 1 Batterymarch Park, Quincy, MA 02169-7471.

NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems,* 2015 edition.

Chapter 3 Definitions

3.1* General. The definitions contained in this chapter shall apply to the terms used in this standard. Where terms are not defined in this chapter or within another chapter, they shall be defined using their ordinarily accepted meanings within the context in which they are used. *Merriam-Webster's Collegiate Dictionary*, 11th edition, shall be the source for the ordinarily accepted meaning.

3.2 NFPA Official Definitions.

3.2.1* Approved. Acceptable to the authority having jurisdiction.

3.2.2* Authority Having Jurisdiction (AHJ). An organization, office, or individual responsible for enforcing the requirements of a code or standard, or for approving equipment, materials, an installation, or a procedure.

3.2.3* Listed. Equipment, materials, or services included in a list published by an organization that is acceptable to the authority having jurisdiction and concerned with evaluation of products or services, that maintains periodic inspection of production of listed equipment or materials or periodic evaluation of services, and whose listing states that either the equipment, material, or service meets appropriate designated standards or has been tested and found suitable for a specified purpose.

3.2.4 Shall. Indicates a mandatory requirement.

3.2.5 Should. Indicates a recommendation or that which is advised but not required.

3.2.6 Standard. A document, the main text of which contains only mandatory provisions using the word "shall" to indicate requirements and which is in a form generally suitable for mandatory reference by another standard or code or for adoption into law. Nonmandatory provisions are not to be considered a part of the requirements of a standard and shall be located in an appendix, annex, footnote, informational note, or other means as permitted in the *Manual of Style for NFPA Technical Committee Documents.*

3.3 General Definitions.

3.3.1 Fire Resistance Rating. The time, in minutes or hours, that materials or assemblies have withstood a fire exposure as determined by the tests, or methods based on tests, prescribed by this standard. [**5000,** 2015]

3.3.2* Flame Spread Index. A number obtained according to ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials,* or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials.*

3.3.3 Limited-Combustible Material. See 4.1.6.

3.3.4 Noncombustible Material. See 4.1.5.

Chapter 4 Types of Construction

4.1 General. [**5000:**7.2.1]

4.1.1* Buildings and structures shall be classified according to their type of construction, which shall be based upon one of five basic types of construction designated as Type I, Type II, Type III, Type IV, and Type V, with fire resistance ratings not less than those specified in Table 4.1.1 and Sections 4.3 through 4.6 and with fire resistance ratings meeting the requirements of Chapter 5. [**5000:**7.2.1.1]

4.1.2 Where two or more types of construction are used in the same building, the entire building shall be classified as the least type of construction in the building and shall be subject to the requirements for that type, except as permitted by other provisions of *NFPA 5000.* [**5000:**7.2.1.2]

4.1.3 Requirements for specific materials, types of construction, and fire protection shall be minimum requirements, and any material, type of construction, or fire protection affording safety or a fire resistance rating equal to or greater than that provided in *NFPA 5000*, shall be permitted. [**5000:**7.2.1.3]

4.1.4 Materials shall be in accordance with all of the following, except as modified by any special requirements in Section 4.3:

(1) *NFPA 5000*, Chapter 41, Concrete
(2) *NFPA 5000*, Chapter 42, Aluminum
(3) *NFPA 5000*, Chapter 43, Masonry
(4) *NFPA 5000*, Chapter 44, Steel
(5) *NFPA 5000*, Chapter 45, Wood
(6) *NFPA 5000*, Chapter 46, Glass and Glazing
(7) *NFPA 5000*, Chapter 47, Gypsum Board, Lath, and Plaster
(8) *NFPA 5000*, Chapter 48, Plastics

[**5000:**7.2.1.4]

4.1.5 Noncombustible Material.

4.1.5.1* The material that complies with any of the following shall be considered a noncombustible material:

(1)*The material that, in the form in which it is used and under the conditions anticipated, will not ignite, burn, support combustion, or release flammable vapors, when subjected to fire or heat
(2) The material that is reported as passing ASTM E 136, *Standard Test Method for Behavior of Materials in a Vertical Tube Furnace at 750 Degrees C*
(3) The material that is reported as complying with the pass/fail criteria of ASTM E 136 when tested in accordance with the test method and procedure in ASTM E 2652, *Standard Test Method for Behavior of Materials in a Tube Furnace with a Cone-shaped Airflow Stabilizer, at 750 Degrees C.*

[**5000:**7.1.4.1.1]

4.1.5.2 Where the term *limited-combustible* is used in this Code, it shall also include the term *noncombustible.* [**5000:**7.1.4.1.2]

[c]See 4.3.2.12, 4.4.2.3, and 4.5.6.8.
[**5000:** Table 7.2.1.1]

4.1.6* Limited-Combustible Material. A material shall be considered a limited-combustible material where both of the following conditions of 4.1.6.1 and 4.1.6.2, and the conditions of either 4.1.6.3 or 4.1.6.4 are met. [**5000:**7.1.4.2]

4.1.6.1 The material does not comply with the requirements for a noncombustible material, in accordance with 4.1.5. [**5000:**7.1.4.2(1)]

4.1.6.2 The material, in the form in which it is used, exhibits a potential heat value not exceeding 3500 Btu/lb (8141 kJ/kg), when tested in accordance with NFPA 259, *Standard Test Method for Potential Heat of Building Materials*. [**5000:**7.1.4.2(2)]

4.1.6.3 The material shall have a structural base of a noncombustible material with a surfacing not exceeding a thickness of ⅛ in. (3.2 mm) where the surfacing exhibits a flame spread index not greater than 50 when tested in accordance with ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials* or ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials*. [**5000:**7.1.4.2.1]

4.1.6.4 The material shall be composed of materials that in the form and thickness used, neither exhibit a flame spread index greater than 25 nor evidence of continued progressive combustion when tested in accordance with ASTM E 84 or ANSI/UL 723, and are of such composition that all surfaces that would be exposed by cutting through the material on any plane would neither exhibit a flame spread index greater than 25 nor exhibit evidence of continued progressive combustion when tested in accordance with ASTM E 84 or ANSI/UL 723. [**5000:**7.1.4.2.2]

4.1.6.5 Where the term *limited-combustible* is used in this Code, it shall also include the term *noncombustible*. [**5000:**7.1.4.2.3]

4.2 Reserved.

4.3 Type I (442 or 332) and Type II (222, 111, or 000) Construction. [**5000:**7.2.3]

4.3.1 Type I and Type II Construction. Type I (442 or 332) and Type II (222, 111, or 000) construction shall be those types in which the fire walls, structural elements, walls, arches, floors, and roofs are of approved noncombustible or limited-combustible materials. [**5000:**7.2.3.1]

4.3.2 Special Requirements — Type I and Type II Construction. The special requirements in 4.3.2.1 through 4.3.2.20 shall apply to Type I and Type II construction. [**5000:**7.2.3.2]

4.3.2.1 Wood Sleepers. Where wood sleepers are used for installing wood flooring on noncombustible floors, the furring space shall be filled with noncombustible or limited-combustible material or shall be fireblocked so that there will be no open space exceeding 100 ft^2 (9 m^2) in area under the flooring. [**5000:**7.2.3.2.1]

4.3.2.2 Sleeper Space. The furring spaces created by sleepers in 4.3.2.1 shall be filled solidly under all permanent partitions to prevent spread of fire under the flooring. [**5000:**7.2.3.2.2]

4.3.2.3 Mezzanine Floors in Type I and Type II (222 or 111) Construction. Mezzanine floors in Type I and Type II (222 or 111) construction shall have a fire resistance rating of not less than 1 hour. [**5000:**7.2.3.2.3]

4.3.2.4 Mezzanine Floors in Type II (000) Construction. Mezzanine floors in Type II (000) construction shall not be required to have a fire resistance rating. [**5000:**7.2.3.2.4]

4.3.2.5 Platforms. Permanent platforms shall be constructed of noncombustible or limited-combustible materials. [**5000:**7.2.3.2.5]

4.3.2.6 Space Beneath Platforms. When the space beneath any permanent platform is used for storage or any other purpose other than equipment, wiring, or plumbing, the floor construction shall have a fire resistance rating not less than 1 hour. [**5000:**7.2.3.2.6]

4.3.2.7 Fire-Retardant-Treated Wood Platforms. Fire-retardant-treated wood shall be permitted for permanent platforms that do not exceed 3000 ft^2 (278 m^2), that are not more than 30 in. (760 mm) above the floor, and that do not occupy more than 50 percent of the floor area of the room or space in which they are located. [**5000:**7.2.3.2.7]

4.3.2.8 Roofs 20 ft (6100 mm) or More Above Any Floor. In occupancies other than mercantile, industrial, or storage occupancies with ordinary or high hazard contents, or other occupancies with high hazard contents exceeding the maximum allowable quantities (MAQ) per control area as set forth in 34.1.3 of *NFPA 5000*, the fire-resistive protection of the roof-ceiling assembly required by Table 4.1.1 shall not be required where every part of the roof/ceiling assembly is 20 ft (6100 mm) or more above any floor immediately below. [**5000:**7.2.3.2.8]

4.3.2.9 Fire-Retardant-Treated Wood Roof. [**5000:**7.2.3.2.9]

4.3.2.9.1 Fire-retardant-treated wood members shall be permitted to be used for unprotected members specified in 4.3.2.8. [**5000:**7.2.3.2.9.1]

4.3.2.9.2 Fire-retardant-treated wood shall be permitted for roof construction, including girders and trusses, under the following conditions:

(1) In Type II buildings
(2) In Type I buildings where the number of stories is two or fewer
(3) In Type I buildings where the number of stories is three or more when the vertical distance from the floor to the roof is 20 ft (6100 mm) or more

[**5000:**7.2.3.2.9.2]

4.3.2.10 Heavy Timber Structural Elements. In all occupancies, heavy timber structural members shall be permitted to be used for the roof construction where a 1-hour fire resistance rating or less is required. [**5000:**7.2.3.2.10]

4.3.2.11 Interior Nonbearing Walls. [**5000:**7.2.3.2.11]

4.3.2.11.1 Interior nonbearing walls shall be constructed of noncombustible or limited-combustible materials. [**5000:**7.2.3.2.11.1]

4.3.2.11.2 Interior nonbearing walls required to have a fire resistance rating of 2 hours or less shall be permitted to be fire-retardant-treated wood enclosed within noncombustible or limited-combustible materials, provided that such walls are not used as shaft enclosures. [**5000:**7.2.3.2.11.2]

4.3.2.12 Exterior Nonbearing Walls. Nonbearing exterior walls shall be constructed of noncombustible materials, limited-combustible materials, or materials specified in 4.3.2.12.1 or 4.3.2.12.2. [**5000:**7.2.3.2.12]

4.3.2.12.1 Fire-retardant-treated wood shall be permitted in exterior nonbearing walls when such walls are not required to have fire resistance ratings. [**5000:**7.2.3.2.12.1]

4.3.2.12.2 Exterior nonbearing walls tested in accordance with, and meeting the conditions of acceptance of, NFPA 285, *Standard Fire Test Method for Evaluation of Fire Propagation Characteristics of Exterior Non-Load-Bearing Wall Assemblies Containing Combustible Components*, shall be permitted. [**5000:**7.2.3.2.12.2]

4.3.2.13 Combustible Materials. Combustible materials shall be permitted in accordance with the following:

(1) Foam plastic insulation complying with Section 48.4 of *NFPA 5000*
(2) Metal composite material complying with Section 37.4 of *NFPA 5000*
(3) Thermal and acoustical insulation, other than foam plastic, complying with Section 8.16 of *NFPA 5000*
(4) Interior floor finish and interior finish, trim, and millwork, such as doors, door frames, window sashes, and window frames
(5) Light-transmitting plastic complying with Sections 38.11 and 48.7 of *NFPA 5000*
(6) Class A, Class B, or Class C roof coverings
(7) Blocking

[**5000:**7.2.3.2.13]

4.3.2.14 Ceiling Cavity Plenums and Raised Floor Plenums. The space between the top of the finished ceiling and the underside of the floor or roof above and the space between the top of the finished floor and the underside of a raised floor shall be permitted to be used to supply air to the occupied area or return and exhaust air from the occupied area, provided that the requirements of 4.3.2.15 through 4.3.2.20 are met.

4.3.2.15 Plenum Materials Combustibility. Materials exposed to the airflow within ceiling cavity plenums and raised floor plenums shall comply with NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*.

4.3.2.15.1 Fire-retardant-treated wood complying with, Chapter 45 of *NFPA 5000* shall be permitted.

4.3.2.16 Plenum Fire Stopping. The integrity of the fire stopping for penetrations shall be maintained.

4.3.2.17 Plenum Light Diffusers. Light diffusers, other than those made of metal or glass, used in air-handling light fixtures shall be listed and marked as follows:

Fixture Light Diffusers for Air-Handling Fixtures

4.3.2.18 Plenum Air Temperature. The temperature of air delivered to plenums shall not exceed 250°F (121°C).

4.3.2.19 Plenum Materials Exposure. Materials used in the construction of a plenum shall be suitable for continuous exposure to the temperature and humidity conditions of the environmental air in the plenum.

4.3.2.20 Ceiling Plenum Tested Assembly. Where the plenum is a part of a floor/ceiling or roof/ceiling assembly that has been tested or investigated and assigned a fire resistance rating of 1 hour or more, and the assembly contains air ducts and openings for air ducts, all the materials and the construction of the assembly, including the air duct materials and the size and protection of the openings, shall conform with the design of the fire resistance–rated assembly, as tested in accordance with ASTM E 119, *Standard Test Methods for Fire Tests of Building Construction and Materials*; or UL 263, *Standard for Fire Tests of Building Construction and Materials*. [**5000:**8.2.1.4]

4.4 Type III (211 or 200) Construction. [**5000:**7.2.4]

4.4.1 Type III Construction. Type III (211 or 200) construction shall be that type in which exterior walls and structural elements that are portions of exterior walls are of approved noncombustible or limited-combustible materials, and in which fire walls, interior structural elements, walls, arches, floors, and roofs are entirely or partially of wood of smaller dimensions than required for Type IV construction or are of approved noncombustible, limited-combustible, or other approved combustible materials. [**5000:**7.2.4.1]

4.4.2 Special Requirements — Type III Construction. The special requirements in 4.4.2.1 through 4.4.2.3 shall apply to Type III construction. [**5000:**7.2.4.2]

4.4.2.1 Fire-Retardant-Treated Wood. Approved fire-retardant-treated wood framing shall be permitted within the assembly of exterior walls having a required fire resistance rating of 2 hours or less and a horizontal separation of not less than 60 in. (1525 mm), provided that the fire resistance rating is maintained and the exposed outer and inner faces of such walls are constructed of limited-combustible or noncombustible materials. [**5000:**7.2.4.2.1]

4.4.2.2 Heavy Timber. Wood columns and arches conforming to heavy timber sizes shall be permitted where exterior walls are required to have a 1-hour fire resistance rating or less. [**5000:**7.2.4.2.2]

4.4.2.3 Exterior Nonbearing Walls. Exterior nonbearing walls tested in accordance with, and meeting the conditions of acceptance of, NFPA 285, *Standard Fire Test Method for Evaluation of Fire Propagation Characteristics of Exterior Non-Load-Bearing Wall Assemblies Containing Combustible Components*, shall be permitted. [**5000:**7.2.4.2.3]

4.5 Type IV (2HH) Construction. [**5000:**7.2.5]

4.5.1 Type IV Construction. Type IV (2HH) construction shall be that type in which fire walls, exterior walls, and interior bearing walls and structural elements that are portions of such walls are of approved noncombustible or limited-combustible materials. Other interior structural elements, arches, floors, and roofs shall be of solid or laminated wood without concealed spaces and shall comply with the allowable dimensions of 4.5.5. [**5000:**7.2.5.1]

4.5.2 Exterior Wall Separation. Exterior walls greater than 30 ft (9.1 m) from the property line shall be permitted to be of heavy timber construction, provided that the 2-hour rating as required by Table 4.1.1 is maintained and such walls contain no combustible concealed spaces. [**5000:**7.2.5.2]

4.5.3 Interior Columns, Arches, Beams, Girders, and Trusses. Interior columns, arches, beams, girders, and trusses of approved materials other than wood shall be permitted, provided that they are protected to provide a fire resistance rating of not less than 1 hour. [**5000:**7.2.5.3]

4.5.4 Concealed Space. Certain concealed spaces shall be permitted in accordance with 4.5.5.3.4. [**5000:**7.2.5.4]

4.5.5 Type IV (2HH) Allowable Dimensions. All dimensions in 4.5.5 shall be considered nominal. [**5000:**7.2.5.5]

4.5.5.1 Columns. [**5000:**7.2.5.5.3]

4.5.5.1.1 Wood columns supporting floor loads shall be not less than 8 in. (205 mm) in any dimension. [**5000:**7.2.5.5.3.1]

4.5.5.1.2 Wood columns supporting only roof loads shall be not less than 6 in. (150 mm) in width and not less than 8 in. (205 mm) in depth. [**5000:**7.2.5.5.3.2]

4.5.5.2 Beams. [**5000:**7.2.5.5.4]

4.5.5.2.1 Wood beams and girders supporting floor loads shall be not less than 6 in. (150 mm) in width and not less than 10 in. (255 mm) in depth. [**5000:**7.2.5.5.4.1]

4.5.5.2.2 Wood beams and girders and other roof framing supporting roof loads only shall be not less than 4 in. (100 mm) in width and not less than 6 in. (150 mm) in depth. [**5000:**7.2.5.5.4.2]

4.5.5.3 Arches. [**5000:**7.2.5.5.5]

4.5.5.3.1 Framed or glued laminated arches that spring from grade or the floor line, and timber trusses that support floor loads, shall be not less than 8 in. (205 mm) in width or depth. [**5000:**7.2.5.5.3.1]

4.5.5.3.2 Framed or glued laminated arches for roof construction that spring from the finished ground level or the floor line and do not support floor loads shall have members not less than 6 in. (150 mm) in width and not less than 8 in. (205 mm) in depth for the lower half of the member height and not less than 6 in. (150 mm) in depth for the upper half of the member height. [**5000:**7.2.5.5.5.2]

4.5.5.3.3 Framed or glued laminated arches for roof construction that spring from the top of walls or wall abutments, and timber trusses that do not support floor loads, shall have members not less than 4 in. (100 mm) in width and not less than 6 in. (150 mm) in depth. [**5000:**7.2.5.5.5.3]

4.5.5.3.4 Spaced members shall be permitted to be composed of two or more pieces not less than 3 in. (75 mm) in thickness where blocked solidly throughout their intervening spaces or where such spaces are tightly closed by a continuous wood cover plate not less than 2 in. (51 mm) in thickness that is secured to the underside of the members. [**5000:**7.2.5.5.5.4]

4.5.5.4 Splice Plates. Splice plates shall be not less than 3 in. (75 mm) in thickness. [**5000:**7.2.5.5.6]

4.5.5.5 Floors. Floors shall be constructed of spline or tongue-and-groove plank not less than 3 in. (75 mm) in thickness that is covered with 1 in. (25 mm) tongue-and-groove flooring, laid crosswise or diagonally to the plank, or with ½ in. (13 mm) wood structural panel; or they shall be constructed of laminated planks not less than 4 in. (100 mm) in width, set close together on edge, spiked at intervals of 18 in. (455 mm), and covered with 1 in. (25 mm) tongue-and-groove flooring, laid crosswise or diagonally to the plank, or with ½ in. (13 mm) wood structural panel. [**5000:**7.2.5.5.7]

4.5.5.6 Roof Decks. Roof decks shall be constructed of spline or tongue-and-groove plank not less than 2 in. (51 mm) in thickness; or of laminated planks not less than 3 in. (75 mm) in width, set close together on edge, and laid as required for floors; or of 1⅛ in. (29 mm) thick interior wood structural panel (exterior glue); or of approved noncombustible or limited-combustible materials of equivalent fire durability. [**5000:**7.2.5.5.8]

4.5.6 Special Requirements — Type IV Construction. The special requirements in 4.5.6.1 through 4.5.6.8 shall apply to Type IV construction. [**5000:**7.2.5.6]

4.5.6.1 Structural Elements. Structural elements shall be of heavy timber members (sawn or glued-laminated) or of fire resistance–rated construction as set forth in Table 4.1.1 when materials other than heavy timber are used. [**5000:**7.2.5.6.1]

4.5.6.2 Columns, Arches, Beams, and Roof Decking. Where horizontal separation of 20 ft (6100 mm) or more is provided, wood columns, arches, beams, and roof decking conforming to the requirements for heavy timber in 4.5.5 shall be permitted to be used on the exterior of the building. [**5000:**7.2.5.6.2]

4.5.6.3 Partitions. Permanent partitions shall be permitted to be of solid wood construction formed by not less than two layers of matched boards of 1 in. (25 mm) nominal thickness or of 1-hour fire resistance–rated construction as set forth in Table 4.1.1. [**5000:**7.2.5.6.3]

4.5.6.4 Floors. Floors shall be permitted to be of heavy timber, masonry, concrete, wood, or steel and shall be constructed as required in Chapter 8 of *NFPA 5000*. [**5000:**7.2.5.6.4]

4.5.6.5 Roofs. Roofs of 1-hour fire resistance–rated construction shall be permitted. [**5000:**7.2.5.6.5]

4.5.6.6 Stairways. [**5000:**7.2.5.6.6]

4.5.6.6.1 Stairways shall be permitted to be constructed with wood treads and risers of not less than 2 in. (51 mm) nominal thickness. [**5000:**7.2.5.6.6.1]

4.5.6.6.2 Where built-on, laminated, or plank inclines are required for floors, stairways shall be permitted to be 1 in. (25 mm) nominal thickness or shall be permitted to be constructed as required for buildings of Type I or Type II construction. [**5000:**7.2.5.6.6.2]

4.5.6.7 Exterior Walls. Approved fire-retardant-treated wood framing shall be permitted within the assembly of exterior walls having a required fire resistance rating of 2 hours or less and a horizontal separation of not less than 60 in. (1525 mm), provided that the fire resistance rating is maintained and the exposed outer and inner faces of such walls are constructed of limited-combustible or noncombustible materials. [**5000:**7.2.5.6.7]

4.5.6.8 Exterior Nonbearing Walls. Exterior nonbearing walls tested in accordance with, and meeting the conditions of acceptance of, NFPA 285, *Standard Fire Test Method for Evaluation of Fire Propagation Characteristics of Exterior Non-Load-Bearing Wall Assemblies Containing Combustible Components*, shall be permitted. [**5000:**7.2.5.6.8]

4.6 Type V (111 or 000) Construction. Type V (111 or 000) construction shall be that type in which structural elements, walls, arches, floors, and roofs are entirely or partially of wood or other approved material. [**5000:**7.2.6]

Chapter 5 Fire Resistance Rating Requirements for Structural Elements

5.1 Fire Resistance Rating Requirements.

5.1.1 The fire resistance ratings of structural elements and building assemblies shall be determined in accordance with Section 8.2 in *NFPA 5000, Building Construction and Safety Code*, or 8.2.3 in NFPA *101, Life Safety Code*.

5.1.2 Fire resistance protection shall be provided for structural elements as set forth in Chapter 5.

5.1.3 Structural elements shall meet the requirements of 5.1.3.1 through 5.1.3.3.

5.1.3.1 Structural elements, floors, and bearing walls shall have a fire resistance rating not less than the fire resistance rating required for the structural element, bearing or nonbearing wall, floor, or roof they support. [**5000:**7.2.7.2.1]

5.1.3.2 Structural elements, floors, and bearing walls shall be required to have only the fire resistance rating required for the construction classification of the building, provided that both of the following criteria are met:

(1) The structural elements support nonbearing wall or partition assemblies having a required fire resistance rating of 1 hour or less.
(2) The structural elements do not serve as exit enclosures, protection for vertical openings, or occupancy separations.

[**5000:**7.2.7.2.2]

5.1.3.3 Structural elements, such as girders, beams, trusses, and spandrels, that have direct connections to columns carrying gravity loads, and that are essential to the stability of the building as a whole, shall have a fire resistance rating not less than that of the columns to which they are connected. [**5000:**7.2.7.2.3]

5.1.4 Structural elements required to have a fire resistance rating and that support more than two floors, one floor and roof, a bearing wall, or a nonbearing wall more than two stories high shall be individually protected on all sides for their full length with materials providing the required fire resistance rating. [**5000:**7.2.7.3]

5.1.5* Structural elements, other than those specified in 5.1.3, required to have a fire resistance rating shall be protected by individual encasement, or by membrane or ceiling protection in accordance with *NFPA 5000*, Section 8.6, or a combination of both. [**5000:**7.2.7.4]

5.1.6 In addition to the requirements of 5.1.3 and 5.1.4, columns shall meet the following requirements:

(1) Where columns require a fire resistance rating, the entire column, including its connections to beams or girders, shall be individually protected.
(2) Where the column extends through a ceiling, the fire-resistive protection provided for the column shall be continuous from the top of the floor through the ceiling space to the top of the column.

[**5000:**7.2.7.5]

5.1.7 Structural elements complying with Section 4.5 shall not be required to comply with 5.1.4. [**5000:**7.2.7.6]

5.1.8 The required thickness and construction of fire-resistive materials or assemblies enclosing trusses shall be based on one of the following:

(1) Results of full-scale tests or combinations of tests on truss components
(2) Approved calculations based on such tests to verify that the assembly is provided with the required fire resistance rating in accordance with 8.2.3 of *NFPA 5000*

[**5000:**7.2.7.7]

5.1.9 The fire resistance rating required for external structural elements located beyond the perimeter of the building floor area shall be permitted to be calculated by using analytical methods in accordance with the provisions set forth in 8.2.3 of *NFPA 5000*. [**5000:**7.2.7.8]

5.1.10 Structural elements within exterior walls or located along the exterior perimeter of a building or structure shall have a fire resistance rating as required by Table 4.1.1 for exterior bearing walls based on the type of construction. [**5000:**7.2.7.9]

5.1.11* Structural elements within an exterior wall located where openings are not permitted, or where protection of openings is required in accordance with 7.3.5 of *NFPA 5000*, shall have a fire resistance rating based on protection against exterior fire exposure as required for exterior bearing walls or the structural element, whichever requires the greater fire resistance rating. [**5000:**7.2.7.10]

5.1.12 The edges of lugs, brackets, rivets, and bolt heads attached to structural elements shall be permitted to extend to within 1 in. (25 mm) of the surface of the fire-resistive protection. [**5000:**7.2.7.11]

5.1.13 Conduits, pipes, or ducts shall not be embedded within the required fire-resistive protection of any structural elements requiring individual encasement to achieve the required fire resistance rating. [**5000:**7.2.7.12]

5.1.14 Fire-resistive materials covering columns required to have a fire resistance rating, where exposed to impact damage by moving vehicles, handling of merchandise, or by other means, shall be protected from damage. [**5000:**7.2.7.13]

5.1.15 In load bearing, light frame walls requiring a fire resistance rating, membrane protection shall not be required to extend beyond the edge or flange of the construction in openings that are framed or where doors or windows are installed. [**5000:**7.2.7.14]

Annex A Explanatory Material

Annex A is not a part of the requirements of this NFPA document but is included for informational purposes only. This annex contains explanatory material, numbered to correspond with the applicable text paragraphs.

A.1.1 It is necessary for the user to consider the influence of location, occupancy, exterior exposure, possibility of mechanical and physical damage to fire-resistant material, and other features that could impose additional requirements for safeguarding life and property, as commonly covered in building codes.

For information on the construction of fire walls and fire barrier walls, see NFPA 221, *Standard for High Challenge Fire Walls, Fire Walls, and Fire Barrier Walls*. For the installation of opening protection, see NFPA 80, *Standard for Fire Doors and Other Opening Protectives* and NFPA 90A, *Standard for the Installation of Air-Conditioning and Ventilating Systems*.

A.3.1 These definitions apply to the materials used in the construction of buildings but do not apply to furnishings, the contents of buildings, or the fire hazard evaluation of materials.

A.3.2.1 Approved. The National Fire Protection Association does not approve, inspect, or certify any installations, procedures, equipment, or materials; nor does it approve or evaluate testing laboratories. In determining the acceptability of installations, procedures, equipment, or materials, the authority having jurisdiction may base acceptance on compliance with NFPA or other appropriate standards. In the absence of such standards, said authority may require evidence of proper installation, procedure, or use. The authority having jurisdiction may also refer to the listings or labeling practices of an organization that is concerned with product evaluations and is thus in a position to determine compliance with appropriate standards for the current production of listed items.

A.3.2.2 Authority Having Jurisdiction (AHJ). The phrase "authority having jurisdiction," or its acronym AHJ, is used in NFPA documents in a broad manner, since jurisdictions and approval agencies vary, as do their responsibilities. Where public safety is primary, the authority having jurisdiction may be a federal, state, local, or other regional department or individual such as a fire chief; fire marshal; chief of a fire prevention bureau, labor department, or health department; building official; electrical inspector; or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the authority having jurisdiction. In many circumstances, the property owner or his or her designated agent assumes the role of the authority having jurisdiction; at government installations, the commanding officer or departmental official may be the authority having jurisdiction.

A.3.2.3 Listed. The means for identifying listed equipment may vary for each organization concerned with product evaluation; some organizations do not recognize equipment as listed unless it is also labeled. The authority having jurisdiction should utilize the system employed by the listing organization to identify a listed product.

A.3.3.2 Flame Spread Index. Under the criteria of ASTM E 84, *Standard Test Method for Surface Burning Characteristics of Building Materials,* and ANSI/UL 723, *Standard for Test for Surface Burning Characteristics of Building Materials* the flame spread index is expressed numerically on a scale for which the zero point is fixed by the performance of inorganic-reinforced cement board and the

100 point (approximately) is fixed by the performance of untreated red oak flooring.

A.4.1.1 The system of designating types of construction also includes a specific breakdown of the types of construction through the use of Arabic numbers. These Arabic numbers follow the roman numeral notation where identifying a type of construction [eg., Type I(442), Type II(111), Type III(200)] and indicate the fire resistance rating requirements for certain structural elements as follows:

(1) First Arabic number — exterior bearing walls
(2) Second Arabic number — columns, beams, girders, trusses and arches, supporting bearing walls, columns, or loads from more than one floor
(3) Third Arabic number — floor construction

Table A.4.1.1 provides a comparison of similar types of construction for various model building codes.
[**5000:** A.7.2.1.1]

A.4.1.5.1 The provisions of 4.1.5.1 do not require inherently noncombustible materials to be tested in order to be classified as noncombustible materials. [**5000:** A.7.1.4.1]

A.4.1.5.1(1) Examples of such materials include steel, concrete, masonry, and glass. [**5000:** A.7.1.4.1.1(1)]

A.4.1.6 Material subject to increase in combustibility or flame spread index beyond the limits herein established through the effects of age, moisture, or other atmosphereic condition is considered combustible. *(See NFPA 259, Standard Test Method for Potential Heat of Building Materials.)*

A.5.1.5 Fire resistance–rated bearing wall assemblies, floor/ceiling assemblies, and roof/ceiling assemblies that are not addressed by 5.1.4 can intersect and provide protection to each other to the extent that the same level of protection is provided by the individual protective elements that intersect.

A.5.1.11 It is not the intent to require protection of structural elements against exterior fire exposure due merely to the presence of fire sprinklers or an occupiable exterior space, such as a porch or balcony, unless specifically required by other codes, such as *NFPA 5000, Building Construction and Safety Code.*

NFPA® 221

Standard for

High Challenge Fire Walls, Fire Walls, and Fire Barrier Walls

2015 Edition

This edition of NFPA 221, *Standard for High Challenge Fire Walls, Fire Walls, and Fire Barrier Walls,* was prepared by the Technical Committee on Building Construction. It was issued by the Standards Council on April 29, 2014, with an effective date of May 19, 2014, and supersedes all previous editions.

This edition of NFPA 221 was approved as an American National Standard on May 19, 2014.

Origin and Development of NFPA 221

The Technical Committee on Building Construction undertook a project to develop a new document to govern fire walls in 1991. At the time, no standard existed to assist code authorities, architects, or engineers on the criteria that were necessary to properly design and construct a fire wall. The first edition of NFPA 221 was issued in 1994. It contained information on various types of fire walls including basic design criteria, proper protection of penetrations, and special design practices for exterior protection features.

The 1997 edition of NFPA 221 contained several changes, including the addition of specific criteria for treatment of seismic separation assemblies, additional criteria for proper protection of raceway penetrations, and the addition of several suggested protection schemes for properly protecting an egress door located in a fire wall.

The 2000 edition addressed specific testing criteria for performance of rated assemblies that included expansion, seismic, and control joints in fire wall and fire barrier wall assemblies. In addition, a second test protocol was recognized for tests of through penetrations.

The 2006 edition introduced two distinct types of fire walls. Presented in Chapter 5, the "high challenge fire wall" requirements are an evolution of the fire wall requirements found in the 2000 edition of NFPA 221, while the "fire wall" requirements presented in Chapter 6 are based upon the requirements found in the 2003 edition of *NFPA 5000®, Building Construction and Safety Code®*. Chapter 4 of this document contains extracts from *NFPA 5000*, Chapter 8, on such topics as analytical methods, duct and air-transfer openings, joints, opening protectives, and penetrations. Please note these extracts were stylistically adjusted to reflect this document's exclusive focus on walls by eliminating references to floors, floor-ceiling assemblies, smoke dampers, and partitions.

The 2009 edition was updated to reflect changes to Chapter 8 of *NFPA 5000*. Other changes included recognition of the new criteria used to determine building height and grade geometries, further clarifications as to where a provision applies to a particular type of wall, and the addition of a new requirement concerning horizontal exits served by bridges between buildings.

The 2012 edition was a reaffirmation of the previous edition, with updated references to reflect changes in UL and ASTM documents.

ASCE definitions are reprinted with permission from ASCE.

For the 2015 edition, extracts from *NFPA 5000* have been removed. *NFPA 5000* now extracts material from NFPA 221. Definitions and referenced documents have also been updated.

This list represents the membership at the time the Committee was balloted on the final text of this edition. Since that time, changes in the membership may have occurred. A key to classifications is found at the back of the document.

NOTE: Membership on a committee shall not in and of itself constitute an endorsement of the Association or any document developed by the committee on which the member serves.

Committee Scope: This committee shall have primary responsibility for documents on the selection and design of types of building construction, exterior walls, building height and area, fire walls, and fire barrier walls, as they relate to the protection of life and property from fire. For the processing of NFPA 5000, Chapter 7, and Sections 8.3 and 8.4, this committee reports directly to the NFPA 5000 TCC; whereas, for the processing of NFPA 220 and NFPA 221, this committee does not report to the NFPA 5000 TCC.
